effects of variations in women's employment in the agricultural sector), Collver and Langlois found that the average activity rate of females within the age group 15 to 64 years was highest in the economically most developed countries, lowest in the least developed, and intermediate in a group of countries coming in between on the scale of economic development. Here again, though, the variations among individual countries were so great as to deprive the averages of much significance. The authors of this study concluded that economic progress might bring either an increase or a decrease in women's participation in the labour force, depending on the level of the female activity rate at the start and on cultural traits relevant to "the speed with which adjustments are made between the family and work". They also noted that the effect of economic development was to diminish participation in some occupations and industries (especially those carried on within the home) while increasing it in others; thus the net effect on the total female activity rate would depend on the circumstances in each country. It is possible also that apparent effects may be illusory in some cases.<sup>79</sup>

(a) *Marital status, motherhood, and economic activity of women*

46. The extent of women's participation in the labour force is related more or less closely in different societies to their marital status and the number and ages of children under their care, as these factors affect their needs for income, the amount of time and energy which they can spare for extra-domestic activities, and social concepts of their proper role. Thus the size of the female labour force may be influenced to an important extent by the ages at which women marry, the frequencies of non-marriage, widowhood, and other forms of broken marriage, and the level and age-pattern of fertility rates. Conversely, variations in female activity rates due to other factors may react upon patterns of behaviour relating to marriage and childbearing.

47. In Western industrialized countries, the great majority of young women work for their living from the time they leave school at least until their marriage. Activity rates for single women in these countries appear to be, on the average, some 15 per cent below those of men at ages 20-34 years. Comparing the average rates for single women in industrialized countries as shown in table IX.6 with the corresponding rates for males in table IX.3, one can see that the difference widens considerably in the older working age groups, thus suggesting that women who remain unmarried tend to withdraw from the labour force earlier than men do.<sup>80</sup> Single women account for a large majority of the female labour

force in some countries, their share of the total exceeding 70 per cent in Norway, for example, and 80 per cent in Ireland according to censuses taken around 1960.<sup>81</sup> Among Western industrialized countries, the United States of America ranks lowest in the share of single women in the female labour force (24 per cent at the census of 1960).

TABLE IX.6. AVERAGE AGE-SPECIFIC ACTIVITY RATES OF FEMALES CLASSIFIED BY MARITAL STATUS IN TWELVE INDUSTRIALIZED COUNTRIES,<sup>a</sup> ACCORDING TO RESULTS OF CENSUSES BETWEEN 1948 AND 1956

Age (years)	Single	Married	Widowed, divorced or separated
15 and over .....	63.8	19.2	27.8
15-19 .....	55.7	24.3	b
20-24 .....	80.9	25.4	b

35-44 .....	74.2	21.1	61.7
45-54 .....	69.1	20.4	51.6
55-64 .....	52.1	14.1	30.3
65 and over .....	18.5	6.5	8.5

SOURCE: United Nations, *Demographic Aspects of Manpower* ... (1962). Adapted from tables 6.1 and appendix tables A-11 to A-13.

<sup>a</sup> Unweighted means of percentages of economically active among female population of specified age and marital status: censuses of Australia, Canada, England and Wales, France, Federal Republic of Germany, Ireland, Israel, Japan, New Zealand, Norway, Sweden and the United States of America.

<sup>b</sup> Numbers too small for calculation of reliable activity rates.

48. The level of the total female activity rate depends mainly on the extent of gainful employment of married women, who make up a large majority of all women in the potentially employable age groups. In Western industrialized countries, the activity rates of married women are much lower than those of single women,<sup>82</sup> but they differ widely from country to country. Among the countries for which averages are shown in table IX.6, the percentages of all married women 15 years of age and over recorded as economically active in the censuses taken around 1950 ranged from about 5 per cent in Ireland and Norway to 46.5 per cent in Japan.<sup>83</sup> Widowed, divorced, and separated women have activity rates below those of single women but generally much higher than those of married women of corresponding ages.

49. In the USSR and some Eastern European countries not included in the averages in table IX.6, the activity rates of married women in particular are undoubtedly

<sup>81</sup> United Nations, *Demographic Yearbook*, 1964 ... (1965).

<sup>82</sup> Married men, on the contrary, tend to have somewhat higher activity rates than single men do, but the variations of activity rates according to marital status are much less pronounced in the male than in the female population. For example, see United Nations, Economic Commission for Latin America, *Some Aspects of Population Growth in Colombia* (1962), part 2, p. 38; Taeuber and Taeuber, *The Changing Population of the United States* (1958), p. 222.

<sup>83</sup> United Nations, *Demographic Aspects of Manpower* ... (1962), table 6.1, p. 37. Activity rates of females specific for age and marital status are tabulated by countries in tables A-11, A-12 and A-13 of the same report.

<sup>79</sup> Collver and Langlois, "The female labor force ..." (1962). Where the extent of women's engagement as unpaid agricultural workers is greatly understated by the census returns, a false picture of higher female activity rates in urban-industrial than in rural-agricultural areas may appear, and an illusion of rising rates in the country's total female population as industrialization and urbanization progress.

<sup>80</sup> The number of countries and the census dates used in computing the rates in tables IX.3 and IX.6 differ, but the broad comparison being made is unlikely to be affected by these differences.

<sup>a</sup> Consensually married women (if classified separately) have been combined with married women for the purpose of these calculations.

<sup>b</sup> Persons 14 years of age reported as economically active are included in the numerators for calculation of these rates.

much higher than the typical range in Western countries. For example, in Czechoslovakia, 1961 census data show that nearly two thirds of married women aged 35-49 years were economically active.<sup>84</sup>

50. Marital status classifications for the female labour force are available for only a few developing countries and the examples of age-specific activity rates for single and married females in such countries, shown in table IX.7, cannot be trusted to be representative. It is certain that much higher percentages of both single and married women are classified as economically active in the censuses of some agricultural countries not shown in the table, since this can be readily inferred from the high activity rates in the female population as a whole, recorded, for example, in Thailand (over 85 per cent of all females between the ages of 15 and 50) and Niger (over 98 per cent between the ages of 14 and 60). In those agricultural countries where the recorded activity rates of married women are very low (represented by the example of Morocco in table IX.7), it is likely that in reality, many farmers' wives share at least to some extent in the farm work. The same observation applies to unmarried daughters in farm households. Thus the fact that the age-specific activity rates for single females recorded in the countries included in table IX.7 are below the typical range for industrialized countries, can be considered as a reflection of incomplete reporting of their services as unpaid family workers and limited opportunities for their employment in paid jobs.<sup>85</sup>

<sup>84</sup> Czechoslovakia, Ústřední Komise Lidové Kontroly a Statistiky, *Vývoj společnosti ČSSR v číslech* ... (1965), p. 193. See also United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1968* ... (1969), p. 250.

<sup>85</sup> Additional factors tending to depress activity rates of single females in some agricultural and semi-agricultural countries are social disapproval of the employment of marriageable daughters outside the home, reporting of many consensually married women as single, and high rates of illegitimacy, meaning that many single women have maternal responsibilities interfering with their employment. It is also possible that, where marriage is early and nearly universal, the few women remaining single at employable adult ages suffer a high incidence of disabilities.

51. The responsibilities of motherhood are the main inhibition to employment of married women in Western industrialized countries, although even those who have no children exhibit lower activity rates than single women do.<sup>86</sup> In England and Wales, for example, a tabulation of women married only once and still married at the 1951 census, showed that half of those who were childless and 20 per cent of those who were mothers were economically active.<sup>87</sup> The larger the number of children, the lower the activity rate of mothers, but the ages of the children may be as important as the number, or more so. It has been shown that in the United States of America, nothing is as effective in keeping a woman out of the labour force as the presence of a child below

<sup>86</sup> The following works are among many in which maternal responsibilities have been studied as a factor affecting activity rates of women in Western industrialized countries: Gendell, "The influence of family-building ..." (1967); United Nations, *Demographic Aspects of Manpower* ... (1962), pp. 49-53; Denmark, Statistiske Department, "Frugtbarheden i og holdbarheden ..." (1955); Kelsall and Mitchell, "Married women and employment ..." (1959); Stewart, "Future trends in the employment ..." (1961); Jephcott, Seear and Smith, *Married Women Working* (1962); Girard, "Le budget-temps de la femme mariée dans les agglomérations urbaines" (1958); Girard and Bastide, "Le budget-temps de la femme mariée à la campagne" (1959); Bloch and Praderie, *La population active* ... (1966); Guilbert and Isambert-Jamati, "La répartition de la main-d'œuvre ..." (1961); Guélaud-Leridon, *Recherches sur la condition féminine* ... (1967), p. 82; Adams and Gendriesch, "Familienstruktur und Frauenerwerbstätigkeit" (1965); Horányi, "A nők foglalkoztatottságának ..." (1965), p. 196; Pfeil, *Die Berufstätigkeit von Müttern* ... (1961); Germany, Federal Republic, Statistisches Bundesamt, "Die erwerbstätigen Ehefrauen ..." (1956); Widstam, "Giftna kvinnors yrkesverksamhet ..." (1958); Dahlström et al., *Studieförbundet Näringsliv* ... (1963); Bancroft, *The American Labor Force* ... (1958), chap. 3; Long, *The Labor Force under Changing* ... (1958), pp. 68-70; Lebergott, "Population change and the supply of labor" (1958); Perrella, "Marital and family characteristics ..." (1964); United States, National Manpower Council, *Womanpower* (1957); Myrdal and Klein, *Women's Two Roles* ... (1968), p. 71. See also the works cited in chapter IV on economic activity of women as a factor affecting fertility.

<sup>87</sup> United Nations, *Demographic Aspects of Manpower* ... (1962), p. 53.

school age.<sup>88</sup> Mothers who enter the labour force are more likely than non-mothers to be employed part-time and intermittently, and the average amount of their time devoted to income-producing occupations varies according to the number and ages of their children.<sup>89</sup> These factors also affect the activity rates of widows, divorcees, and separated women, but they are more likely than married women to go to work in spite of maternal responsibilities.<sup>90</sup> In the socialist countries, extensive public provision for day-care of the children of working mothers helps overcome obstacles to their employment, but even in these circumstances, the presence of several young children depresses the activity rate of the mothers.<sup>91</sup>

52. The conditions of participation for mothers in the labour force are not the same in a rural-agricultural setting where women carry on economic activities mainly at home, on family farms, in family operated retail stores, home-handicraft industries etc. Data from rural areas of little-developed agricultural countries show little relationship, or a positive relationship, between the number of children and activity rates of married women.<sup>92</sup> Likewise, in the agricultural population of industrialized countries, the inverse relationship does not hold as a general rule,<sup>93</sup> but does appear in cities in less developed countries.<sup>94</sup>

#### (b) Age-patterns for female activity rates

53. The ages at which women marry and bear children, together with the conditions of participation of wives and

A-17; Morgan, Sirageldin and Baerwaldt, *Productive Americans* (1966); Girard, "Le budget-temps de la femme mariée dans les agglomérations urbaines" (1958); Girard and Bastide, "Le budget-temps de la femme mariée à la campagne" (1959).

<sup>90</sup> Bancroft, *The American Labor Force* ... (1958), p. 61.

<sup>91</sup> Juraček, "Některé ponýatky o ekonomické činnosti ..." (1964), p. 351; Kuba, "Zamestnanost žien a rozmiestňovanie dorastu" (1964); Prokopec, "Udaná žena v rodine a zamestnanosti, 1961" (1963); Hungary, Kozponti Statisztikai Hivatal, *A termékenységi családtervezési* ... (1963), table 8.3, p. 89; Józefowicz, "Hipoteza zmian aktywności zawodowej ..." (1965), p. 15. The latter study showed that for women in the older working ages, activity rates did not vary much according to the number of children, but for the younger women who were likely to have small children, the variation in activity rates was substantial. See also Berent, "Some demographic aspects of female employment ..." (1970), particularly p. 188; Sonin, "Aktualnye problemy uluchsheniia ..." (1967), p. 255; and Vdovenko and Korchagin, "Zaniatost v domashnem khoziaistve ..." (1969), pp. 208-209.

<sup>92</sup> Jaffe and Azumi, "The birth rate and cottage industries ..." (1967), pp. 6-7.

<sup>93</sup> In Poland activity rates for married women in the villages were little affected by the numbers of children. Berent, "Some demographic aspects of female employment ..." (1970), pp. 184, 189. Positive relationships are indicated by data for the agricultural population in the Federal Republic of Germany and Japan, for instance; see United Nations, *Demographic Aspects of Manpower* ... (1962), p. 53; Germany, Federal Republic, Statistisches Bundesamt, "Die Erwerbstätigkeit von Frauen ..." (1960), p. 41.

<sup>94</sup> For example, see United Nations, *The Mysore Population Study* ... (1961); Tabah and Samuel, "Preliminary findings of a survey ..." (1962).

mothers in economic activities, affect not only the size of the female labour force but also the relative levels of specific activity rates in different age groups of the female population. The age-patterns of these rates differ markedly in different countries and have changed greatly in some countries during recent decades. The estimated activity rates for 1960, given in table IX.3, show that in the more developed regions, labour force participation reaches a maximum in ages around 20 years and declines progressively in higher age groups, while the average activity rates for developing regions are on a much more even level over the range from 15 to 64 years. These averages conceal a diversity of patterns in different geographical regions and in individual countries, especially within the developing group.<sup>95</sup>

54. Two forms of age-curves of female activity rates commonly found among Western industrialized countries are represented by the data for Northern America and Oceania. In both cases, the female activity rates rise in the teen ages to a peak somewhere about the age of 20 and then enter a decline which reflects the increasing proportions of married women, and of mothers among the married. Some time after age 30, the curve for Oceania flattens while that for Northern America rises again towards a second peak around the age of 50 years—this second peak being about as high as the initial peak. The rise to the second peak reflects the growing freedom of middle-aged mothers from maternal cares as their children grow older. It appears that women in Canada and the United States of America take advantage of this opportunity to seek paid jobs in their middle age to a greater extent than do the women of Australia and New Zealand. Curves for both of the above types appear in different countries of Western and Northern Europe. For example, a fairly pronounced secondary peak appears in the data for France and Norway, while those for Denmark, the Netherlands and Sweden show a flattened curve at ages 35 to 55.

55. The forms of age-curves for female activity rates currently found in most industrialized countries have evolved only recently. Before the Second World War, the most common form of these curves in Western industrialized countries seems to have been one in which the rates declined without interruption after the initial peak around the age of 20.<sup>96</sup> There has been a general trend in the post-war period of increasing labour force participation by women at ages in the forties and fifties, while the activity rates for women between the ages of about 25 and 35 have increased less or diminished in some countries. Where these divergent trends have been most pronounced, the double-peaked curve of the North American type has evolved, while elsewhere the curve has taken a form closer to that shown for Oceania.

<sup>95</sup> In the analysis of the data derived from censuses taken between 1946 and 1958, nine regional types of age-curves for female rates were defined by averaging the rates for selected countries within each region. United Nations, *Demographic Aspects of Manpower* ... (1962), table 5.2 and figure 5.

<sup>96</sup> United Nations, *Demographic Aspects of Manpower* ... (1962), p. 30. On changes in female activity rates in Japan, see Umemura, "An analysis of employment ..." (1962); and Taeuber, *The Population of Japan* (1958), p. 81.

Female activity rates in the countries of Southern Europe typically follow the pattern that was common in Northern and Western Europe before the Second World War; thus, the activity rates show a gradual fall with increasing age throughout the age range from 25-65 years.<sup>97</sup> Still another pattern is evident in many Eastern European countries, where very high and nearly constant activity rates are maintained from about ages 20-50.<sup>98</sup>

56. Quite different patterns of age-curves for female activity rates are found within the various developing regions. In Latin America, for example, activity rates reach a peak around 20 and then decline continuously in higher ages.<sup>99</sup> A similar pattern is found in the statistics of some Middle Eastern countries and China (Taiwan). This pattern represents a situation in which the participation of women in the labour force, as recorded in the censuses, is mainly an urban characteristic and those who participate are chiefly young women not yet married or not having children. In contrast, the curve for India and Pakistan is domed in shape and rather similar to the typical age-curve for male activity rates, though at a much lower level. Curves of this form at lower or higher levels are also found in a number of African countries, including the Democratic Republic of the Congo, Morocco, Mozambique, Senegal and Tunisia. They represent a predominantly rural-agricultural pattern of women's economic activities, affected relatively little, if at all, by the changing maternal responsibilities at different ages in the life cycle, and also relatively little by differences between activity rates for the married and the single, since very few women in the countries concerned remain single after the age of 20.<sup>100</sup>

### (c) Trends of female activity rates

57. In some countries, recorded activity rates for females have been rising and offsetting the falling trend in male rates, while elsewhere the trend of the female rates also has been downward. The diversity of trends is apparent among countries of all degrees of industrialization, as shown in table IX.5. Female rates have increased since the Second World War in a majority of industrialized countries and decreased in a majority of semi-industrialized countries, but the average amounts of the changes have not been very great. For agricultural countries, the data are too few to give a reliable indication of the direction of the dominant trend.<sup>101</sup>

<sup>97</sup> United Nations, *Demographic Yearbook, 1964* ... (1965), table 8.

<sup>98</sup> Berent, "Some demographic aspects of female employment ..." (1970), pp. 181-182.

<sup>99</sup> See, for example, Ypsilantis, "World and regional estimates ..." (1969), table 4.

<sup>100</sup> For example, among the countries included in table IX.7, single women made up only 18 per cent of the labour force in Morocco, whereas their share was 56 per cent in Peru and 57 per cent in Panama.

<sup>101</sup> International Labour Office estimates of female activity rates for 1950 and 1960 show a rising trend both in the developed and developing regions, though the increase in the latter derives mainly from the estimated rise in China. International Labour Office, *Labour Force Projections* ... (1971), part V, table 2. Among the factors cited by Bloch and Praderie as contributing to rising activity rates for women in developed countries were: changing social

58. In a number of industrialized countries, as female activity rates rose and male rates fell recently, women began to contribute a major share in the growth of the labour force. Females, mostly past 40 years of age, accounted for almost two thirds of the increase in the civilian labour force during the 1950s in Great Britain<sup>102</sup> and nearly three fifths in the United States of America.<sup>103</sup> The post-war trends have been similar in Australia, Austria, Belgium, Canada and Sweden. In a number of Eastern European countries the share of total labour force growth accounted for by women has been particularly high.<sup>104</sup> Even where the female activity rates have decreased, their decrease has been less than that of the male rates in most instances, so that the labour force sex ratio has shifted to the feminine side. This is the case of France, Italy, Norway, Ireland, the Netherlands, and New Zealand. The Federal Republic of Germany and Japan are cases illustrating increasing rates both for males and females, due to changes in population age structure. In these cases, the increases in female rates exceed those of male rates.<sup>105</sup>

59. In a longer-range view, neither an increase nor decrease in women's participation in economic activities can be discerned as a predominant tendency among industrialized countries. In a comparative study of census data since 1910 for ten industrialized countries, the long-range trend of age-standardized female activity rates was found to be definitely upward in four countries (Australia, Canada, England and Wales, and the United States of America), downward in three (France, Sweden, and Switzerland) and relatively level or unsteady in three

norms concerning the work of married women, use of time-saving appliances for household work, and improvements in the provision of day-care facilities for children. See their *La population active* ... (1966), p. 48.

(1962); Taeuber, *The Population of Japan* (1962), p. 81.

(Japan, the Netherlands, New Zealand).<sup>106</sup> In another study, the conclusion was drawn that the general pattern was one of increasing uniformity in the levels of female activity rates in industrialized countries, the rates rising where they were previously low and remaining stable or falling where they were previously high.<sup>107</sup> For the United States of America, the validity of the statistical indications of a long-range trend of rising activity rates of women has been questioned.<sup>108</sup>

60. In the countries where great increases in female activity rates have been recorded in the censuses since the early decades of the present century, these can be attributed mainly to increasing participation by married women in economic activities, although the activity rates for single, widowed, divorced, and separated women also have risen. In the United States of America, for example, where only 13 per cent of all women in the labour force in 1890 were married, the ratio increased to 60 per cent by 1960.<sup>109</sup> Increasing trends in specific activity rates for married women (and for single, widowed, divorced, and separated women as well) have been observed even in some countries where the total female activity rate has been sagging during recent decades. This paradox is explained by changes in the marital status composition of the female population<sup>110</sup>—especially those brought about by the “marriage boom” during the aftermath of the Second World War in many industrialized countries. The spate of early marriages as well as the rise in marital fertility rates at that time depressed activity rates of young women in some countries and prevented substantial increases which might otherwise have occurred elsewhere.

61. During the first half of the present century, the secular trend of decreasing birth rates in industrialized countries helped to smooth the way for increasing economic activity by married women. Growing freedom from maternal cares was only a minor factor, though, in causing increases in women's activity rates recorded in the United States of America. More important factors were the expanding demand for labour in occupations regarded as suitable for women and changing attitudes and aspirations which predisposed more and more

married women to seek paid jobs when they could spare the time from domestic duties.<sup>111</sup>

62. According to one hypothesis, changes in the activity rates of certain sex-age groups in the population tend to induce compensating changes in other groups, so that the extent of labour force participation on the part of the whole population of employable ages is not greatly affected. This might imply that rising activity rates for women in countries like the United States of America have been caused partly by declining activity rates for males under 20 and over 55 years of age, leaving gaps in the labour force which women came in to fill or, that women crowding into the labour force added impetus to the forces which were pushing older men out and delaying the entrance of young people. Support for this hypothesis has been found in observations of relative stability over long time-periods in age-standardized activity rates for the two sexes in a number of industrialized countries.<sup>112</sup> However, as the findings reviewed above indicate, such a complementary relationship between trends of male and female activity rates does not appear to be a universal rule.

63. Among developing countries, a long-range decreasing trend in female activity rates has been traced in India back to the beginning of the present century, and has been interpreted primarily as a result of industrialization, urbanization, and limited opportunities for women's employment in urban industries.<sup>113</sup> In Egypt, a steep downward trend in female rates (as well as male rates for age groups at the two extremes of the working-life span) since the census of 1927 has been attributed to failure of the growth of employment opportunities in agriculture to keep pace with the growth of the rural population.<sup>114</sup> In Jamaica, where the female rates have been decreasing since the late nineteenth century, the trend has been considered partly as a reflection of the gradual transformation of customs inherited from the former slave-labour régime.<sup>115</sup> In West Malaysia, activity rates among Malay and Indian women fell between 1947 and 1957 as a result of increasing urbanization.<sup>116</sup> In the Republic of Korea, on the other hand, a study of the results of the censuses since 1930 failed to reveal any consistent long-range trend of female activity rates; and the same observation applies to Puerto Rico, when women employed in home needlework are excluded from the labour force totals.<sup>117</sup> The trend has been upward, in a number of Latin American countries such as

<sup>106</sup> United Nations, *Demographic Aspects of Manpower* ... (1962), table 5.3. In the United Kingdom, an increase in the proportion of married women and of older women during the first half of the twentieth century depressed the total female activity rate, but if allowance is made for these factors, labour force participation by women has shown a significant long-term rise. ## B. Demographic and economic factors in labour force size and growth

### 1. THE ROLES OF FERTILITY, MORTALITY, POPULATION AGE STRUCTURE, AND AGE-SPECIFIC ACTIVITY RATES

64. As mentioned above, the age structure of the population, as determined by fertility, mortality, and migration, plays a leading role in determining the size of the labour force. The sex composition of the population in potentially employable age groups is also pertinent, but the sex ratio ordinarily varies too little to be a major factor, except where sex-selective migration occurs on a large scale or war losses create a severe imbalance between the numbers of the sexes.<sup>119</sup> The relative effects of age structure and age-specific activity rates in determining the proportion of workers in a population are examined in the present section, and the role of migration is discussed in the following section.

65. As shown in chapter VIII, the share of working-age adults in the population is generally smaller in economically less developed than in more developed countries because of higher fertility making for proportionately larger numbers of children in the former countries. On this account, with equal age-specific activity rates, the less developed countries would generally have a smaller labour force in proportion to population, and a higher dependency ratio.

66. The eventual effects of different levels of demographic variables and of age-specific activity rates are difficult to study in actual populations. However, the extension of stable population analysis to the economi-

cally active population provides a convenient tool for assessing the long-term effects on total activity rates of (a) varying fertility and mortality rates, operating through the age structure, and of (b) different age-specific activity rates. The results of such an analysis for the male population, summarized in table IX.8, bring out the importance of fertility as a primary determinant of the proportion between the labour force and population in the long run. Under given conditions of mortality and age-specific activity rates, when the gross reproduction rate drops from 3.0 to 1.0, the total male activity rate in these models increases by some 20 per cent of the male population. Lowering mortality rates (that is, increasing life expectation) with the other factors constant has an opposite but less pronounced effect. Under given conditions of mortality and fertility, the ratio of the male labour force to the male population would be appreciably reduced by a change from the pattern of age-specific activity rates typical of agricultural countries to that typical of industrialized countries. However, the effect of changing activity rates, even when combined with the effect produced by declining mortality, would be outweighed by that of a large decrease in fertility.

67. As the stable models represent the structure and dynamics of the population which would eventually result from a continuation of given rates of fertility, mortality and participation in economic activities, they do not show the shorter-run effects of changes in these rates. The shorter-run effects, which may be of great importance in a country undergoing a demographic and economic transition, can be studied by means of the kind of projections illustrated with reference to Brazil in table IX.9. These show how hypothetical changes in fertility, mortality, and age-specific male activity rates, operating separately and in combinations, would affect the total male activity rate and the rate of growth of Brazil's male labour force during a 25-year period. The specific activity rates are assumed to shift from those recorded in Brazil to those recorded in Sweden at the 1950 censuses, thus decreasing in the age groups under 20 and over 55 years by amounts similar, on the whole, to the differences between average male rates for agricultural and industrialized countries. It can be seen that such a change in specific activity rates, under any of the given assumptions as to fertility and mortality trends, makes for an appreciable reduction both of the total

<sup>118</sup> United Nations, *Demographic Yearbook*, 1956 ... (1957), table 10; and ———, 1964 ... (1965), table 8. See also van den Boomen, "Population and labour force growth ..." (1967); You, "Growth and structure of the labour force ..." (1963); Bean, "Utilisation of human resources ..." (1968), pp. 402-403.

TABLE IX.9. PROJECTIONS OF MALE LABOUR FORCE OF BRAZIL, 1950-1955 TO 1975-1980

1950-1955 estimates	Assumption as to trend of age-specific activity rates	1975-1980 projections		
		A: Constant mortality and fertility	B: Declining mortality, constant fertility	C: Declining mortality and fertility
<i>Total male activity rate (male labour force as percentage of total male population)</i>				
56.3 .....	Constant specific activity rates	56.5	55.0	59.5
	Changing specific activity rates	51.7	50.1	54.8
<i>Annual rate of growth per 1,000 of male labour force</i>				
23.4 .....	Constant specific activity rates	22.2	28.2	22.6
	Changing specific activity rates	19.6	24.6	20.3

*Note:* Definition of assumptions: decline of mortality rates according to the assumption adopted for projections of Brazil's population in United Nations, *The Population of South America 1950-1980* (1955), implying rise of expectation of life at birth from 44.1 years in 1950-1955 to 56.6 years in 1975-1980. Decline of fertility according to the assumption of the "low" variant of the same projections, implying decrease of the sex-age-adjusted birth rate from 43.0 in 1950-1955 to 31.6 in 1975-1980. Change of male age-specific activity rates from those recorded in Brazil at the 1950 census, for 1950-1955, to those recorded in the 1950 census of Sweden, for 1975-1980.

male activity rate and the rate of growth of the male labour force. This would suffice, in Brazil's case, to counterbalance the upward pressure on the total male activity rate resulting from a considerable decline of fertility, or to prevent a great acceleration of the male labour force growth rate resulting from a decline of mortality with fertility remaining constant.<sup>120</sup> While the results are presented here in terms of activity rates, the effects of changes in any of the factors on labour force size are obviously also of importance.

68. In view of the possible interdependence of factors, all attempts to isolate the effects of particular factors are made with reservations. For example, it is likely that some of the developments influential in decreasing mortality and fertility rates in Western countries during the course of their industrialization also contributed to the decreasing trends in male activity rates in the youngest and oldest age groups. On the other hand, growth and changing structure of the population may influence specific activity rates. For example, it has been suggested that in less developed countries, the high proportion of children in the population may be one factor tending to force young people to go to work early and men to continue working at an advanced age so as to provide for the dependent children.<sup>121</sup> With regard to industrialized countries, it has been suggested that if the increasing proportion of old people in the population continues, the

time may come when the trend toward earlier retirement will be reversed as a matter of economic necessity.<sup>122</sup>

69. Subject to reservations regarding interdependence, the method of standardization can be used to estimate how much of the difference between crude activity rates in two populations, or how much of the change in the rate for a given population during a period of time, is attributable to changes in population composition and how much to changes in specific activity rates.<sup>123</sup> For example, in the United Nations study of data from censuses taken around 1950, the following averages of crude male activity rates, actual and standardized for age composition of the population, were obtained:<sup>124</sup>

	Actual rates (1)	Age- standardized rates (2)	Difference (1)-(2)
Industrialized countries . . . .	62.2	60.5	+ 1.7
Semi-industrialized countries . . . .	57.8	62.8	- 5.0
Agricultural countries . . . . .	55.2	65.1	- 9.9

The effects of differences in male age-specific activity rates among the three groups of countries are measured by comparing the age-standardized rates (which show how the crude activity rates would have differed if the age composition of the population had been the same in all three groups). The difference between the actual and age-standardized rates measures the effect of differences in the population age structure, bringing out the strong

<sup>120</sup> It should be noted that these calculations are not perfectly comparable with the example of long-run changes either in activity or fertility or mortality rates studied in the preceding paragraph. The results of an analysis along similar lines involving projections of the combined population of seven developing countries is presented in Seklani, "Variations de la structure par âge ..." (1961). Coale and Hoover, *Population Growth and Economic Development* ... (1958), chap. 15, present an analysis by means of projections of the effect of a possible decline of fertility upon the growth of the labour force and the dependency ratio in India.

<sup>121</sup> Durand, "Population structure as a factor ..." (1953).

<sup>122</sup> Daric, *Viellissement de la population* ... (1948).

<sup>123</sup> The methodology is discussed and illustrated in Tamasy, "A munkaerő vizsgálatának ..." (1959). The problem of treating the interaction has often been neglected; on this problem, see Durand, *The Labor Force in the United States* ... (1948), pp. 219-220.

<sup>124</sup> United Nations, *Demographic Aspects of Manpower* ... (1962), table 3.4. The age composition of the Netherlands population as of 1947 was used as a standard in these calculations. Different values would be obtained by the choice of different standards.

negative effect of this factor in the agricultural countries (where fertility is high) and its lesser effect in semi-industrialized countries (where the average level of fertility is somewhat lower).<sup>125</sup>

70. In industrialized countries, the long-range trend of decreasing fertility in the past has had a strong tendency to raise crude activity rates or at least to cushion the effects of other factors tending to lower them. For example, in the United States, the decrease in the proportion of children under 14 years of age in the population, due to declining fertility, would have raised the crude activity rate between 1920 and 1940 by 3.5 per cent of the population if other factors had remained equal. Actually, the effect of other factors was to limit the increase of the rate to 2 per cent.<sup>126</sup> Japan derived a like advantage from the sharp decrease of fertility which occurred in that country more recently. This was the cause of an increase in the Japanese male activity rate from 56.0 per cent of the male population in 1940 to 58.5 per cent in 1960; without any change in the age structure of the population, the rate would have decreased by 3.2 per cent.<sup>127</sup>

71. The post war "baby boom" in Western industrialized countries caused a temporary reversal of the trend in their population age structure which tended to depress activity rates. On this account, the increase of the labour force (both sexes) between 1954 and 1964 in France and the Federal Republic of Germany was only about one half as large as it would have been with an unchanged age structure, while age structure changes detracted about one third from the labour force increase in the United States and about one fifth in the United Kingdom and Canada.<sup>128</sup> Recently, the trend has turned again as the birth rates in these countries have subsided and children born in the years of peak fertility have begun to come into the labour force. Eastern European countries and the USSR also experienced a temporary decrease in the proportion of population in certain working ages during the late 1950s as a result of the war-time decrease and post-war recovery of their birth rates.<sup>129</sup>

72. Shifts in the age distribution of the adult population also may influence the labour force trend, but their effects have generally been much less important than the effects of the changing ratios between adult and child population. In France, where the male labour force in proportion to the male population 15 years of age and over decreased from 90.2 per cent in 1911 to 82.2 per cent in 1954, only 0.4 points of this decrease

could be attributed to the increasing proportion of elderly men and other changes in age distribution of the population over 15 years of age. Findings with regard to the trends in other industrialized countries are similar.<sup>130</sup>

73. The age structure of the adult population has more to do with the age composition of the labour force than it does with the crude activity rate. Aging of population in industrialized countries has resulted in a swelling proportion of elderly workers in the labour force in spite of decreasing activity rates for males in the higher age brackets. In the United States of America, for example, the median age of males in the labour force increased from 33.3 years in 1890 to 38.5 in 1950 and the median for females increased even more, from 24.3 to 35.9 years.<sup>131</sup> The question of effects of aging of the labour force upon productive efficiency has engaged the attention of many writers, but the theoretical discussion and results of such empirical research as has been attempted pertaining to this question are inconclusive.<sup>132</sup> It is clear that aging does tend to diminish spatial and occupational mobility and on this account the increasing proportion of elderly workers may aggravate problems of structural unemployment; on the other hand, it may diminish the unemployment associated with absorption of young people into the labour force.<sup>133</sup>

74. In the less developed countries, where the birth rates have remained, in general, on relatively high levels, population age structures as a rule have undergone no very great changes. Appreciable decreases in the proportions of the adult population have been recorded recently, in some of these countries, however, probably as a result of decreasing mortality rates and possibly some increases in fertility. In India, for example, according to the census returns, the 15 to 59 year age group shrank from 60.2 per cent of the total population in 1931 to 57.1 per cent in 1951 and 54.4 per cent in 1961. This factor could account for about one half of the decrease in India's crude activity rate from 43.3 per cent in 1931 to 39.1 per cent in 1951. The change in population age structure also would have reduced the crude activity rate to 37.3 per cent by 1961 if the 1951 ratio of labour force to population 15-59 years of age had applied

<sup>130</sup> United Nations, *Demographic Aspects of Manpower* ... (1962), tables 3.5 and 5.3; Long, *The Labor Force under Changing* ... (1958), chap. 8.

<sup>131</sup> Jaffe and Stewart, *Manpower Resources and Utilization* ... (1951), p. 165. On the long-range pre-war trend in France, see Desmarest, *La politique de la main-d'œuvre* ... (1946), chap. 1; in Belgium, Dereymaeker, "Interaction entre l'économie et la population ..." (1946); in Switzerland, Renggli, "Die wirtschaftlichen Auswirkungen ..." (1938).

<sup>132</sup> For examples of diverse views and conjectures on this question, see: Létinier, "Vue d'ensemble des conséquences ..." (1948); Daric, *Vieillessement de la population* ... (1948); Myrdal, *Population: A Problem for Democracy* (1962); Robbins, "Notes on some probable consequences ..." (1929), p. 75; Notestein *et al.*, *The Future Population of Europe* ... (1944), p. 130; Höök, *Befolkningsutveckling och arbetskraftsförsörjning* (1952), pp. 113-114; United Kingdom, Royal Commission on Population, *Report* ... (1949), p. 114; Spengler, "Some effects of changes ..." (1947); Stassart, *Les avantages et les inconvénients* ... (1965); Michałkiewicz, *Przydatność zawodowa robotników* ... (1962). See also chapter VIII, section D and chapter XIII, section D.

<sup>133</sup> See sections D and E.

<sup>125</sup> The small positive difference for industrialized countries reflects a difference between the average age structure for this group of countries and that of the Netherlands, which was taken as the standard.

<sup>126</sup> Durand, *The Labor Force in the United States* ... (1948), p. 61.

<sup>127</sup> Calculated by standardization with the data shown in Japan, Bureau of Statistics, *1960 Population Census* ... (1964), part 1, pp. 138-141, 226-227. See also Kono, "Jinkogaku-teki yoin no ..." (1959).

<sup>128</sup> Bloch and Praderie, *La population active* ... (1966).

<sup>129</sup> Lungu, "Population and labour force ..." (1965), p. 136. See also Pod'yachikh, *Naselenie SSSR* (1961), p. 29; and Gozulov and Grigoryants, *Narodonaselenie SSSR* ... (1969), pp. 66-67.

in 1961.<sup>134</sup> In Egypt, the percentage of population in the 15 to 64-year age group is estimated to have decreased from 57.8 in 1947 to 54.1 in 1957; in this case, slightly more than one half of the decrease of the recorded crude activity rate (from about 35 to 30 per cent of the total population) could be attributed to the change in age structure.<sup>135</sup> For the developing regions as a whole, Ypsilantis found that both changes in population age structure and, to a lesser extent, changes in age-specific activity rates, led to a decline in the crude male activity rate from about 58 to 55 per cent between 1950 and 1960.<sup>136</sup>

75. The negative effect of falling mortality rates upon the proportion of the working-age population in less developed countries may be offset by positive effects of improving conditions of health upon specific activity rates as well as upon the productive capacity of the labour force. Losses of potential labour supply and impairment of productive efficiency due to illness have been emphasized as factors in the economic problems of less developed countries.<sup>137</sup> For example, according to one estimate, while 3 million people in these countries might die of malaria annually, 300 million might be suffering from the disease, with an annual loss of 20 to 40 working days per worker afflicted.<sup>138</sup> In the Philippines, malaria was found to be largely responsible for a 35 per cent rate of absenteeism among workers in a sample of enterprises; the rate dropped to the range of 2 to 4 per cent after an anti-malaria campaign.<sup>139</sup> However, in a study in the hill region of Mysore State, India, activity rates and measures of the extent of employment during a year were found to be lower in villages where large-scale anti-malarial operations had been conducted than where they had not; thus it was apparent that any positive effect of the anti-malarial campaigns in this area upon labour supply and employment had been relatively slight and had been more than offset by other differences in the circumstances of the two groups of villages.<sup>140</sup>

<sup>134</sup> Calculations based on the figures given by Kalra, "A note on working force ..." (1962), table 10. According to Kalra's figures, the ratio of labour force to population in this age group rose from 68.5 per cent in 1951 to 79.0 per cent in 1961 (approximately the level of 1901-1921); but as noted above, the reality of this change is dubious.

<sup>135</sup> Seklani, "Population active et structures économiques de l'Égypte" (1962). For the trend in Chile, see Herrick, "Efectos económicos de los cambios ..." (1964); in the West Indies, Harewood, "Employment in Grenada in 1960" (1966).

<sup>136</sup> Ypsilantis, "World and regional estimates ..." (1969), p. 46.

<sup>137</sup> For example, see Swaroop, "Study of morbidity ..." (1959); Belshaw, *Population Growth and ...* (1956). Correa, *The Economics of Human Resources* (1963), pp. 43-45, gives estimates of the reduction of "capacity to work" as a result of sickness in various countries, based on a simplified assumption with regard to bed-disability days. In view of reservations with regard to the comparability of available statistical measures of morbidity in various countries, it is difficult to determine whether the prevalence and incidence of disabling diseases are greater or less in less developed than in more developed countries. See India, Cabinet Secretariat, *Report on Morbidity* (1961), pp. 5-7, 28-29.

<sup>138</sup> Swaroop, "Study of morbidity ..." (1959), p. 543.

<sup>139</sup> Belshaw, "Population growth and ..." (1956), p. 135.

<sup>140</sup> United Nations, *The Mysore Population Study ...* (1961), chap. 15.

## 2. THE ROLE OF MIGRATION

76. International migration has often played an important role in improving the balance between the growth of labour supply and demand. Within national boundaries, internal migration takes a larger role, commonly furnishing the major part of labour force increases in cities and regions of rapid economic expansion and serving as an indispensable medium for the spatial redistribution of manpower which the evolution of modern industrial economies demands. Effects of migration on the trends of labour supply in certain occupations and industries are likely to be more important than its influence on the growth of the labour force as a whole.

77. Immigration generally contributes proportionately more to the growth of the labour force than to the growth of population (and emigration detracts proportionately more) on account of the characteristically large proportion of adults of working age among migrants. Thus the short-run effect of migration is generally to raise the crude activity rate in areas of immigration and to lower it in areas of emigration.<sup>141</sup> The longer-run effects are more diffused, especially when the volume of migration varies over time.<sup>142</sup> The advantage for a developed community in recruiting labour supply by immigration has been demonstrated by a calculation which showed that a "stock" of 100 males in the population concerned yielded a gross annual increment of 14 and net increment of 7 to the male labour force, whereas a "flow" of 100 immigrants provided a net increment of some 40 male workers.<sup>143</sup> The effects of migration upon the growth of the labour force and the crude activity rate are conditioned, of course, by the specific activity rates of migrants in various sex-age groups. These may be either higher or lower than the specific activity rates in the non-migrant population, depending on such factors as the proportion of migrants who are accompanied by dependants, the proportion of students among young migrants and retirement patterns among older migrants and any handicaps or advantages of migrants in competing for employment in the area of immigration.<sup>144</sup>

<sup>141</sup> For example, in Puerto Rico, where the male activity rate dropped from 70.4 per cent of the male population 14 years of age and over in 1950 to 65.2 per cent in 1960, it has been estimated that nearly two-thirds of the change could be attributed to net emigration. See Stone, "Net migration and the sex-age ..." (1965), p. 115. Effects of migration have not often been calculated in these terms; a more common practice has been to calculate effects on the proportions of "working age" and "dependent age" groups of the population without reference to activity rates; for example, see Organization for European Economic Cooperation, Manpower Committee, *Demographic Trends in Western Europe ...* (1956), pp. 43-45; Spengler, "Effects produced in receiving ..." (1958), pp. 24-25.

<sup>142</sup> United Nations, *The Aging of Populations ...* (1956), pp. 48-49.

<sup>143</sup> Sadie, "The white labour force ..." (1960), p. 101.

<sup>144</sup> In Israel, the handicaps of new immigrants in education and skills have been reflected in low specific activity rates as well as high unemployment rates, in comparison with the rates of older immigrants and Israel-born population; see Muhsam, "Labour force characteristics ..." (1961), pp. 71-86; Hovne, *The Labor Force in Israel* (1961). On differences between activity rates of interstate migrants and non-migrants in the United States, see Miller, "Migration differentials ..." (1966). On effects of internal migration and population redistribution upon activity rates in Puerto Rico, see Stone, "Population redistribution and economic ..." (1965).

78. The trans-Atlantic migration from Europe, at its height in the late nineteenth and early twentieth centuries, made major contributions to the expansion of labour supply in the United States of America and other countries in the New World. Foreign-born workers made up more than one third of the United States labour force during the four decades preceding the First World War, and it has been found that the volume of the migratory inflow responded positively to variations in demand for labour.<sup>145</sup> The movement also had an appreciable moderating effect on labour force growth in the European homelands, where the rate of natural increase was speeding up. Around 1910, at least one out of every fifteen workers born in Europe (including the present area of the USSR) was living overseas.

79. Although the volume of intercontinental emigration from Europe has diminished considerably in more recent times, it still played a part which was by no means negligible during the period following the Second World War, in keeping up the expansion of labour supply in the United States and other receiving countries in the face of slackening natural increase and declining male activity rates. Net immigration furnished one fifth of the increase of the labour force between 1954 and 1964 in the United States of America and more than one fourth in Canada.<sup>146</sup> In Australia, without immigration, the available male labour force would have grown during 1947-1957 by less than one half of 1 per cent per annum; immigration brought the rate up to nearly 2 per cent.<sup>147</sup> Within Europe, post-war intracontinental movements of workers have been even more important in relative terms, in supplying the manpower needs of the leading industrial countries and easing labour surpluses in less developed areas, particularly the Mediterranean countries. Immigration into France and the Federal Republic of Germany prevented decreases in the labour force which would otherwise have been expected in those countries during 1954-1964. In Italy, net emigration of workers during this period amounted to about 3 per cent of the 1954 labour force, exceeding the growth due to natural increase and changes of activity rates and thus causing Italy's labour force to decrease by about 1.2 per cent during the ten-year interval.<sup>148</sup> Greece, Spain, Turkey, and Yugoslavia also sent out considerable numbers of migrant workers during recent years (see chapter VII, section A).

80. Seasonal and other temporary movements of workers, as well as migration of a more permanent character, are important in meeting labour requirements in many countries. In European countries, work permits of limited duration are used as a device for regulating the flow of such temporary migrant labour according to the needs of the economy. In 1963, there were approximately 2,700,000 temporary migrants working in Western European countries, 800,000 of them being employed in

the Federal Republic of Germany. In Switzerland, they constituted one quarter of the labour force.<sup>149</sup>

81. In Africa, migration of labour within and across national boundaries, much of it having a seasonal character, is an important feature of economic life. Among others, the cocoa plantations of Ghana, the coffee farms of Uganda, the sisal plantations of the United Republic of Tanzania, and the gold mines of South Africa depend on temporary migrants from subsistence-agricultural areas for a major share of their labour supply.<sup>150</sup> The migratory labour system is estimated to involve an annual flow of 2,500,000 or more workers in Africa. In some instances, it depletes male manpower in the areas of emigration by almost 50 per cent during the intermittent spells of wage-labour employment, and wives and children are left the task of caring for the crops.<sup>151</sup> Here, as in the early period of Japanese industrialization and in the case of migrants to the cities in India who return to their villages periodically, the workers remain uncommitted to stable industrial employment.<sup>152</sup>

82. Migration from rural areas to cities—the dominant type of internal migration in most countries—can be viewed as the counterpart in spatial movement of population, for the shift of manpower from agricultural to non-agricultural industries which is an essential feature of the evolution of modern industrial societies. (It is true that this shift does not depend entirely on migration; within limits, it may also be accomplished by the development of non-agricultural economic activities within rural communities or by rural residents commuting to urban jobs.)<sup>153</sup> In terms of labour supply and demand, the “push” factors motivating rural-to-urban migration are identified with demographic pressures generated by natural increase of the rural labour force and technological changes tending to reduce or limit the growth of manpower requirements in agriculture; while the “pull” factors are linked with the growth of demand for labour in the urban-industrial sector.<sup>154</sup> In more developed countries, it is generally recognized that both “push” and “pull” factors have been influential in governing the flow of such migration, although their relative importance has

<sup>153</sup> For example, see Hoffman, “Employment problems of regional . . .” (1964); Frenkel, “Wychodźstwo zawodowe . . .” (1966).

<sup>154</sup> In addition to the factors of labour supply and demand, and the related differences of earnings in the rural and urban sectors, non-economic factors may also be involved in the “push” and “pull” forces; for example, see Fisk, “The mobility of rural labor . . .” (1961).

varied in different countries and periods of time.<sup>155</sup> In less developed countries during recent times, some observers hold that the rising tide of cityward migration has been caused, in most cases, chiefly or wholly by the "push" of a swelling labour surplus in agriculture; whatever "pull" the urban-industrial sector could exert is viewed as having been too weak to influence the volume of the movement significantly.<sup>156</sup>

83. Migration from rural to urban places may lower the total activity rate for the country as a whole, since certain migrants who previously worked in agriculture are less likely to be employed in the towns. The "migration loss" in the labour force resulting from the exodus from agriculture between 1930 and 1960 in Poland was calculated at about 20 per cent of the number of migrants. While the loss was negligible for men in the prime working ages, it was substantial for women of all ages, as well as for boys under 18 years and men 60 years and over.<sup>157</sup> While the general tendency is for rural-urban migration to lower activity rates for males, it may result in an increase in female activity rates in those countries where relatively few women are employed in agriculture.

### 3. EFFECTS OF INCOME, EDUCATION AND EMPLOYMENT CONDITIONS

84. Levels of income and conditions of employment—that is, the relative scarcity or plenty of employment opportunities, including opportunities for self-employment and unpaid family work as well as paid employment—affect the dimensions and growth of the labour force through influences on the growth and structure of population and on age-specific activity rates. The patterns of these influences are varied and the net effect on the labour force of rising income and expanding employment opportunities may be positive, negative, or nearly neutral according to the circumstances.

85. The influences of economic factors upon the components of population change have been considered in other chapters. In summary, it appears that only through migration do high income and plentiful employment opportunities consistently tend to promote growth in both the population and the labour force, and opposite conditions consistently have a contrary effect. Through migration, these economic factors commonly play a dominant role in the redistribution of the labour force among parts of countries, but ordinarily a less important part in shaping the trends of national labour force growth.

<sup>155</sup> For example, see Lasorsa, "Notes sur les mouvements naturels ..." (1963); Frenkel, *Zatrudnienie w rolnictwie polskim* ... (1968). On occasion, the prevailing direction of the migration from rural to urban areas has been reversed. See Baum, *Population, Manpower and Economic* ... (1961), p. 34.

<sup>156</sup> For example, see United Nations, Economic Commission for Asia and the Far East, *Economic Bulletin for Asia* ... (1957), p. 34; ———, Economic Commission for Latin America, "The demographic situation ..." (1961), pp. 31-32; Desmukh, "Delhi: a study of floating migration" (1956), p. 145; Hájek, "Územní zřetel při zvyšování ..." (1963).

<sup>157</sup> Frenkel, "Wychodźstwo zawodowe ..." (1966), p. 101. For a discussion of employment losses resulting from migration from agriculture in Bulgaria, see Minkov, "Vstreshnite migracionni procesi ..." (1965); and his "Opit za opredeljane ..." (1967).

To the extent that mortality decline is associated with rising income and improving employment conditions, the effect on the numbers of workers would be positive, although in relative terms, the ratio of workers to dependants might decrease, since the effect of mortality decline on age structure is generally to raise the proportion of young children in the population. Variations in mortality in the modern world, however, have come increasingly under the domination of technological developments only loosely connected with economic factors. Regarding fertility, although its recent short-term variations in industrialized countries have been related positively with short-term changes in income and employment opportunities, an opposite relationship is apparent in long-range past trends in these countries, while fertility in less developed countries has shown little sensitivity to varying economic conditions. The main effect of a change in the birth rate upon growth of the labour force is, of course, postponed some 15 or 20 years, while any immediate effect through the influence of women's maternal responsibilities upon their activity rates works in the opposite direction.

86. The international differences and secular trends of specific activity rates, reviewed in section A, exhibit a mixed picture of associations with variations in income. The associations are negative as far as activity rates of males at the two ends of the span of working ages are concerned,<sup>158</sup> sometimes negative and sometimes positive in the case of women's activity rates, while there is little variation in activity rates of men in the central age groups, who provide most of the labour supply in most countries. In industrialized countries, as income has risen in the course of time, contributions to labour supply per head of the male population have been reduced by the shortening of weekly hours of work as well as the decreasing activity rates for males in the youngest and eldest age groups. Women's contributions also have decreased in some industrialized countries while they have increased in others. Present information does not warrant generalizations in these respects with regard to less developed agricultural countries. For associations between the variations in employment conditions and those of activity rates and labour supply contributions per worker, it is more difficult to get a broad view because of the limitations of scope and comparability of employment, unemployment, and underemployment measures.

87. Some attempts have been made to get a better understanding of the economic determinants of activity rates by studying their correlations with income, unemployment, and other variables in annual time-series and cross-sectional data for different areas and population groups within countries. Data on activity rates of family members classified by income of the household head or the family, and of married women according to income or employment status of their husbands, have also been used for this purpose. Research along these lines has been mostly limited to the industrialized market econo-

<sup>158</sup> However, within a group of eleven industrialized countries, differences in male activity rates at ages over 65 years were not found to be correlated significantly with income levels; see Long, *The Labor Force under Changing* ... (1958), p. 7.

mies.<sup>159</sup> In subsistence economies where no labour market in a strict sense exists and in the centrally planned economies where wages are controlled, the relationship of income to activity rates is likely to be of less importance and has not received much study.

88. In studies of cross-sectional data for the United States, Bowen and Finegan found male activity rates to be associated positively, on the whole, with the incomes of employed males, although the implied effect of the income level upon activity rates is relatively slight for males in the central age groups and follows an irregular pattern for younger and older age groups.<sup>160</sup> Married women's activity rates, likewise, have been found to be associated positively with incomes of employed females, but negatively with those of employed married men. For example, a multiple regression analysis of 1960 census data for standard metropolitan areas yielded a coefficient of +.42 for the regression of married women's activity rates upon the median income of females employed 50 weeks or more during 1959 (implying that an increase of one per cent in women's earnings would raise their activity rate by about four tenths of one per cent), while the coefficient was -.63 for the regression upon median income of married male family heads.<sup>161</sup> The latter finding is consistent with cross-sectional data on variations in married women's activity rates classified according to their husbands' incomes. For example, a United States population survey as of March 1960 showed activity rates of married women 20-44 years of age decreasing as their husbands' incomes rose, from 41 per cent for

women whose husbands had less than \$2,000 in income in 1959 down to 15 per cent for those whose husbands had \$10,000 or more.<sup>162</sup> A negative association between activity rates of women and the incomes of men is also found in other industrialized countries,<sup>163</sup> and in less developed countries as well. In India, for example, a study of 1961 census data for the thirteen states showed a significant negative correlation between female activity rates in the rural population and average income per male agricultural worker.<sup>164</sup>

89. According to one hypothesis, an increase in income exerts two contrary influences upon the propensity to be employed: an "income effect" which is negative because higher family incomes mean that family members can afford to devote less time to income-producing work and more to leisure and other activities; and a "substitution effect" which is positive because higher income from employment raises the "opportunity cost" of leisure and other activities. It is argued that while the "income effect" is generally dominant in the case of men, the "substitution effect" may be stronger in the case of women. This hypothesis finds empirical support in the positive association observed between married women's activity rates and the levels of women's earnings, and the negative association between their activity rates and the incomes of their husbands. This has been suggested as an explanation for the divergent secular trends of female and male activity rates accompanying the rising trend of income in the United States of America.<sup>165</sup> Alternative explanations would give more weight to factors other than the income trend which have influenced the trends of male and female activity rates in this country.

90. Educational attainment has sometimes been used as an indicator of socio-economic status, or earning power of workers, in studying the factors which affect female activity rates. Analyses for Canada, based on 1961 census data, show that better educated women were more likely to be in the labour force than the less educated, and that this was true for the entire female population, including married women, whether or not they had children. While the activity rates of married women were thus found to be positively associated with educational attainment, they were negatively associated with the income of the husband, but of the two factors, education appeared to exert a stronger influence.<sup>166</sup>

<sup>159</sup> Pioneering studies in this field in the United States were those of Douglas, *The Theory of Wages* (1934); and Schoenberg and Douglas, "Studies in the supply ..." (1937). Among the most important recent studies are those of Bowen and Finegan, *The Economics of Labor Force Participation* (1969); Cain, *Married Women in the Labor Force* (1966); Finegan, "Hours of work in the United States ..." (1962); Hansen, "The cyclical sensitivity ..." (1961); Long, *The Labor Force under Changing ...* (1958); Mincer, "Labor force participation of married women ..." (1962); Morgan et al., *Income and Welfare in the United States* (1962); Rosett, "Working wives ..." (1958); Strand and Dernburg, "Cyclical variation in civilian ..." (1964). With more particular reference to the effects of employment conditions upon activity rates, see Bowen and Finegan, "Labor force participation ..." (1965); Mincer, "Labor-force participation and unemployment ..." (1966); Tella, "The relation of labor ..." (1964); and his "Labor force sensitivity ..." (1965). On variations in activity rates in "long swings" of economic growth, see Easterlin, "Economic-demographic interactions ..." (1966).

<sup>160</sup> Bowen and Finegan, *The Economics of Labor Force Participation* (1969), particularly pp. 80, 84, 341, 456-457; and their "Labor force participation ..." (1965). Coefficients of regression of activity rates for men of prime working age, youths, elderly men, and married women on various measures of income as well as unemployed rates and other independent variables are presented, as derived from an analysis of 1960, 1950, and 1940 census data for standard metropolitan areas in the United States. A negative correlation between earnings and labour force participation was found for males aged 16-24 years; the authors interpreted this as reflecting the reluctance of employers to hire very many young workers where their wages are high. See *The Economics of Labor Force Participation* (1969), pp. 431-433.

<sup>161</sup> Cain, *Married Women in the Labor Force* (1966), table 15, p. 59. Different values of the coefficients were obtained in an analysis of 1950 census data, *ibid.*, table 11, p. 48. See also Bowen and Finegan, *The Economics of Labor Force Participation* (1969), pp. 161-162, 172-174, 190; and their "Labor force participation ..." (1965); Lebergott, "Population change and the supply of labor" (1958).

<sup>162</sup> Cain, *Married Women in the Labor Force* (1966), p. 3. See also United States, National Manpower Council, *Womanpower* (1957), p. 22; Long, *The Labor Force under Changing ...* (1958), chap. 4; Bancroft, *The American Labor Force ...* (1958), p. 75. Oppenheimer pointed out, however, that according to 1963 survey data, the negative association between female activity rates and husband's income was no longer so uniform. See her *The Female Labor Force ...* (1970), p. 29.

<sup>163</sup> On the variations of British married women's activity rates in relation to their husbands' incomes, see Jephcott, Seear and Smith, *Married Women Working* (1962), p. 103. For France, see Paillat, "Féminisation de la population active ..." (1963), p. 58.

<sup>164</sup> Sinha, "Dynamics of female participation ..." (1965).

<sup>165</sup> Mincer, "Labor force participation of married women ..." (1962); Cain, *Married Women in the Labor Force* (1966), pp. 5-7.

<sup>166</sup> Ostry, *The Female Worker in Canada ...* (1968), pp. 30-32. On the relationship of education and family income to female activity rates in the USSR, see Guseinov and Korchagin, "Voprosy trudovyykh resursov" (1971).

A distinct positive correlation between educational level and female activity rates has been found in a number of other industrialized countries such as Belgium, France, Hungary, the Netherlands, Poland, Sweden and the United States of America, where cross-section analyses have been carried out on the basis of census data.<sup>167</sup> On the other hand, it has been suggested that a similar relationship does not exist in Switzerland.<sup>168</sup> Cross-tabulations of data on education and economic activity are less frequently available for developing countries. In Puerto Rico, a strong positive association between economic activity rates and level of education has been observed, both for the island as a whole, and for the metropolitan area of San Juan.<sup>169</sup> In India the pattern was somewhat different: urban activity rates were found to be lower for literate than for illiterate women, though within the literate group, advanced education appeared to favour increased labour force participation.<sup>170</sup>

91. As was noted in the case of income, it is also considered that varying conditions of employment may exert two contrary influences on activity rates. On the one hand, the labour force may be inflated under conditions of relative shortage of labour and deflated under opposite conditions by the inflow and outflow of marginal workers who can compete for jobs only in a "seller's market" for labour, or who are interested in being employed only when they can find jobs perfectly suited to their tastes. On the other hand, there may be an opposite flow—into the labour force under adverse employment conditions and out under favourable conditions—of secondary breadwinners who are forced by economic necessity to seek work when primary family breadwinners are unemployed or underemployed. These two counteracting influences correspond, respectively, to the "discouraged worker" hypothesis and the "additional worker" hypothesis with regard to variations in activity rates under the pressure of unemployment. The results of empirical studies in the United States imply, on the whole, that the former influence has overbalanced the latter so that activity rates have tended in general to vary inversely with unemployment rates under the conditions which have prevailed in this country since

the 1940s. However, the patterns of associations between these variables appear to have differed in different sex-age groups of the population and to have changed from one date to another.<sup>171</sup> According to Strand and Dernburg, the depressing effect of unemployment upon activity rates is greatest in the initial phase of an employment depression, when the "discouraged worker" influence prevails; whereas the "additional worker" influence gains strength later as adverse employment conditions continue.<sup>172</sup>

92. Studies in other countries also have produced evidence of activity rates sagging under the pressure of unemployment and underemployment.<sup>173</sup> Based on 1954 data for various population groups and districts in Israel, Hovne found significant negative correlations between unemployment and activity rates for males and females in the groups from 35-64 years, though not for younger groups.<sup>174</sup> Similar indications are found in the results of a 1951-1952 survey in the State of Mysore, India, where activity rates in different rural zones and areas of the capital city were shown to vary in inverse association with unemployment and part-year employment rates.<sup>175</sup> In Egypt, it has been suggested (without such empirical evidence) that failure of employment opportunities to expand in pace with the rapid growth of the population was responsible for the decreasing trend of activity rates observed during the last few decades.<sup>176</sup>

93. Activity rates in certain segments of the population may be affected by the composition of employment opportunities as well as their volume. As already noted, the shrinking share of agriculture in the labour force and the decrease in opportunities for self-employment have played a part in shortening the gross years of active life of males in industrializing countries. On the other hand, the growing demand for labour in secretarial, clerical, and other white-collar occupations has been credited as an important factor in the secular increase of female activity rates in some of these countries.<sup>177</sup>

<sup>171</sup> See the results of the analysis by Bowen and Finegan, *The Economics of Labor Force Participation* (1969), particularly pp. 483, 487-489, 510, 526, 533-537; see also their "Labor force participation ..." (1965); Mincer, "Labor-force participation and unemployment ..." (1966).

<sup>172</sup> Strand and Dernburg, "Cyclical variation in civilian ..." (1964). In this connexion, see Proulx, "La variabilité cyclique ..." (1969), on possible reasons for the predominance of the "additional worker" hypothesis in Canada. On the effect of changing unemployment levels upon the rate of continuation of young males in school, see Duncan, "Dropouts and the unemployed" (1965), p. 128.

<sup>173</sup> Regarding post-war experience in European countries, see United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1962* (1963), part 1, chap. 2; ———— *1963* (1964), part 1, chap. 2; Hunter, "Cyclical variations in ..." (1963).

<sup>174</sup> Hovne, *The Labor Force in Israel* (1961), pp. 48-49.

<sup>175</sup> United Nations, *The Mysore Population Study ...* (1961), chap. 15.

<sup>176</sup> Seklani, "Population active et structures économiques de l'Égypte" (1962).

<sup>177</sup> For example, Oppenheimer concluded that an important factor in the accelerated rise in female activity rates between 1940 and 1960 in the United States was the fact that the industries and occupations which were expanding most rapidly were those which were major employers of women. Oppenheimer, *The Female Labor Force ...* (1970), p. 187. See also Lebergott, "Population change

(Continued on next page)

## C. Length of working life and its implications

### 1. TABLES OF WORKING LIFE

94. Among the new possibilities of analysis opened up by the application of demographic techniques to the study of manpower is that of working life expectancy and its implications. Life table techniques have been applied in calculating working life tables which have proved to be a useful tool for studying the processes of labour force growth and replacement and structural change and for estimating such measures as expected lifetime earnings.<sup>178</sup> These techniques have also been applied in studying the process of replacement in particular industries and occupations.<sup>179</sup> The average length of working life or "net expected years of active life"<sup>180</sup> is determined by age-specific activity rates, considered as measures of the probability of a person of either sex being in the labour force at each age, together with the probabilities of survival to various ages as given by a life table.<sup>181</sup> Measures of this average are provided by "tables of working life", which have been calculated for a number of countries.<sup>182</sup> In addition, such tables may

(Footnote 177 continued)  
and the supply of labor" (1958). Examples of empirical studies in the United States in which the occupational composition of demand for labour has been considered as a factor in differences of female activity rates among metropolitan areas are: Belloc, "Labor force participation and employment ..." (1950); Bowen and Finegan, "Labor force participation ..." (1965).

<sup>178</sup> United Nations, *Methods of Analysing Census Data* ... (1968), p. 19.

<sup>179</sup> Benjamin, *Demographic Analysis* (1969), pp. 151-154. Processes of change in labour force structure are discussed in section D of this chapter.

<sup>180</sup> This term is used in opposition to the "gross years of active life", calculated without regard to mortality.

<sup>181</sup> The measure of working-life expectancy includes indiscriminately periods of full-time and part-time work and of unemployment. It can be reduced to a measure of the expected lifetime input of working time by means of data on unemployment and hours of work classified by age and sex. For an example, see Pallós and Valkovics, "A gazdaságilag ..." (1965).

<sup>182</sup> The following is a partial list of works containing various functions of national tables of working life. For Bulgaria, see Kacarov, "Vrhu srednata prod'žitelnost ..." (1961); for Canada, Denton and Ostry, *Working-life Tables for Canadian Males* (1969); for Chile, Sadie, "Población y mano de obra ..." (1969); for France, Daric, *Viellissement de la population* ... (1948); Depoid, "Tables françaises concernant ..." (1951); Naville, "Measurement of working life ..." (1959); for Ghana, Kpedekpo, "Working life tables ..." (1969); for Great Britain, United Kingdom, Ministry of Labour and National Service, *The Length of Working* ... (1959); for Hungary, Pallós and Valkovics, "A gazdaságilag ..." (1965); for India, Cabinet Secretariat, *Report on Some Characteristics* ... (1959), p. 65; Gnanasekaran, "Increasing length of working life ..." (1960); for Jamaica, Roberts, *The Population of Jamaica* (1957), p. 95; for Japan, Kono, *Nihon-jin danshi* ... (1965); Azumi, "Length of work life ..." (1958); for West Malaysia, Saw, "Malaya: Tables of male ..." (1965); for New Zealand, Census and Statistics Department, *Table of Working Life, 1951* ... (1955); for Norway, Thonstad and Sørsveen, "Lengden av den yrkesaktive ..." (1966); for Pakistan, Bean, "Provisional estimates of length ..." (1967); for Panama, García and Castro, *República de Panamá, vol. 2: Proyección* ... (1965); for Poland, Józefowicz, *Zagadnienia stagnacji w zatrudnieniu* (1967), sections 3, 7; Smoliński, "Statystyczne metody mierzenia ..." (1965); for Romania, Ghețau, "Durata medie a vieții ..." (1968); for the United States of America, Bureau of Labor Statistics, *Tables of Working Life* ... (1950); Garfinkle, *Tables of Working Life for Women, 1950* (1957); his "Tables of working life for men, 1960" (1963); and his "The lengthening of working life ..." (1967).

provide age-specific rates of accretion for the labour force by the entrance of new workers, depletion by retirement (that is, voluntary or involuntary withdrawal into inactive status), and depletion by death:<sup>183</sup> also the average ages of entrance into and retirement from the labour force in a cohort of males or females subject to these age-specific rates and the given conditions of mortality.

95. Two alternative measures of the average length of working life can be calculated. The first represents the net expected years of active life for a cohort of males or females at birth, or in the remainder of their lifetime after a given age. This is readily calculated for either sex at each age, from the schedule of age-specific activity rates and the survival functions of the life table.<sup>184</sup> The second measure, referring to males or females in the labour force at a given age, represents their average remaining number of years of active life. Its calculation involves more complications, since entries into the labour force at earlier ages have to be taken into account as well as the possibility of individuals withdrawing and re-entering the labour force once or more during their lifetime, and possible associations between the age of entrance and the age of withdrawal from economic activity. In the circumstances of most countries, while a satisfactory approximation to the latter measure may be derived in the case of males from the age-specific activity rates and survival functions,<sup>185</sup> calculation of the corresponding measure for females requires additional data on the frequencies of first entrance, withdrawal, and re-entrance into the labour force at various ages.<sup>186</sup>

<sup>183</sup> For males, the increments of age-specific activity rates by single years up to the age at which the rate reaches its maximum may be considered as approximate measures of the age-specific rates of accretion by new entries on the assumption that retirements are negligible up to that age. Likewise, decrements of the specific activity rates at higher ages may be taken as approximations to the rates of retirement, while the rate of depletion of the labour force by death at each age is assumed to be the same as the mortality rate in the population of the same age, as given by the life table. For methodological details, see United States of America, Bureau of Labor Statistics, *Tables of Working Life* ... (1950). In the case of females, these methods do not give valid results under the conditions existing in many countries, where considerable numbers of females may withdraw from the labour force at an early age and enter, or re-enter, at a relatively late age. In such circumstances, specific data on the frequencies of entrance, retirement, and re-entrance at various ages are required. In United States tables of working life for females, the age-specific rates for entrance and retirement are separated into parts attributable to changes in marital status and family characteristics and those due to other factors. See Garfinkle, *Tables of Working Life for Women, 1950* (1957).

<sup>184</sup> The measure is obtained by summing the products ( $w_x L_x$ ) of specific activity rates and the life table stationary population by single years of age from the given age up to the end of the life-span, and dividing the sum by the number of survivors ( $l_x$ ) in the life table at the given age.

<sup>185</sup> On the assumption that withdrawals of males from the labour force are negligible below the age at which the specific activity rate ( $w_x$ ) reaches its maximum and entries are negligible above that age, and that the age of withdrawal is independent of the age of entrance, the measure is obtained by substituting the maximum value of ( $w_x$ ) for the observed values at all lower ages, summing the products ( $w_x L_x$ ) from each given age up to the end of the life span, and dividing the sum by ( $w_x L_x$ ) for the given age. For methodological details, see United States of America, Bureau of Labor Statistics, *Tables of Working Life* ... (1950).

<sup>186</sup> For methodological details, see Garfinkle, *Tables of Working Life for Women, 1950* (1957).

TABLE IX.10. AVERAGE EXPECTATION OF LIFE AND NET EXPECTED YEARS OF ACTIVE AND INACTIVE LIFE FOR MALES IN INDUSTRIALIZED, SEMI-INDUSTRIALIZED, AND AGRICULTURAL COUNTRIES, ACCORDING TO DATA FROM CENSUSES TAKEN BETWEEN 1946 AND 1958 AND CORRESPONDING LIFE TABLES

(Figures are unweighted averages of the measures for countries in each group)

Degree of industrialization	At birth			At age 15		
	Expectation of life ( $e_0$ )	Net years of active life	Net years of inactive life	Expectation of life ( $e_{15}$ )	Net years of active life	Net years of inactive life
Industrialized countries . . . . .	65.0	42.2	22.8	54.5	45.3	9.2
Semi-industrialized countries . . . . .	52.8	35.6	17.2	49.5	43.1	6.4
Agricultural countries . . . . .	48.3	33.9	14.4	46.1	41.5	4.6

SOURCE: United Nations, *Demographic Aspects of Manpower* . . . (1962), table 4.4.

Subtraction of the working-life expectancy from the total expectation of life at the given age yields the expected number of years in inactive status.<sup>187</sup>

96. The net expected years of active life of males, at birth and at the age of entrance into the labour force, are considerably greater in industrialized than in agricultural countries on the average, as shown in table IX.10. A comparison in terms of average remaining years of economic activity for males in the labour force, in the younger age brackets, would show a similar difference. The difference is due to lower mortality rates in the industrialized countries, which more than compensate for their relatively low male activity rates in the youngest and eldest groups. The average loss of active years by mortality (measured as the difference between net expected years of active life and gross years as defined in section A above) for males between the ages of 15 and 70 years has been estimated at 4.8 years in industrialized countries, 8.5 years in semi-industrialized, and 11.4 years in agricultural countries.<sup>188</sup> The average length of inactive life of males is also greater in industrialized than in agricultural countries, owing to the combined effects of later entrance and earlier withdrawal from the labour force, with lower mortality rates in industrialized countries. On the average, the years of inactive life are a larger fraction of the total life expectancy of males in industrialized than in agricultural countries (see table IX.10).

97. In the course of time, as the total expectation of life increases, the average length of working life of males in industrialized countries also increases in spite of the decreasing tendency of male activity rates in younger and older age brackets. The average number of years of inactive life increases still more, so that the inactive years represent a growing fraction of the lifetime for males.<sup>189</sup> In most of the less developed countries, data

are lacking for the calculation of long historical series of working life table functions; but it has been found possible in the case of Jamaica to construct such a series going back to 1891. The expected number of active years for males at the age of entrance into the labour force appears to have changed little in Jamaica between 1891 and 1943. Improved chances of survival were balanced by decreases in activity rates at the two ends of the age scale. In Jamaica, as in industrialized countries, the inactive years increased in average number and as a fraction of the total life expectation for males.<sup>190</sup>

## 2. DYNAMIC FUNCTIONS OF THE LABOUR FORCE

98. In a closed population under given conditions of mortality, sex-age structure and age-specific activity rates for each sex, the rate of increase or decrease of the labour force is the net balance of (a) the rate of replenishment by persons entering or re-entering the labour force from the inactive population, (b) the rate of depletion by deaths of the labour force members, and (c) the rate of depletion by retirements (that is, voluntary or involuntary withdrawals into inactive status). The net balance of these three components is the "replacement rate" of the labour force, which is analogous to a rate of natural increase. It may be modified by migration into and out of the area and by changes in the specific activity rates. The ratio of (a) to the sum of (b) and (c) is the labour force "replacement ratio", a sensitive index of pressure on the labour market from new recruits to be placed in proportion to the number of posts being vacated by death and retirement.

99. These components of labour force dynamics have been calculated with the help of a table of working life which provides the age-specific rates corresponding to (a), (b) and (c). These age-specific rates are applied to the corresponding numbers of the actual labour force (as distinct from the labour force in the hypothetical stationary population of the working-life table), and the products summed to obtain totals for all age groups. Alternatively, the components can be estimated for a country during the interval between two censuses, by

<sup>187</sup> Measures of the expected numbers of years of life in the normal ages of economic activity and of dependency, without regard to actual participation in the labour force, are derived from the life table alone. Variations of these measures in space and time have been analysed by Mortara, "Durée de la vie économiquement active . . ." (1951).

<sup>188</sup> United Nations, *Demographic Aspects of Manpower* . . . (1962), table 4.2, p. 18.

<sup>189</sup> Garfinkle, "Changes in working life . . ." (1955), gives measures of long-term changes in the United States. Pallós and Valkovics, "A gazdaságilag . . ." (1965), present a historical series for Hungary,

1910-1960, with reference to males, females, and the two sexes combined. In this case, the trends for both females and males follow the pattern described above.

<sup>190</sup> Roberts, *The Population of Jamaica* (1957), p. 95.

TABLE IX.11. ANNUAL REPLACEMENT RATES AND RATIOS FOR THE MALE LABOUR FORCE AND ANNUAL RATES OF ENTRANCE, RETIREMENT, AND LOSSES BY DEATH, IN STABLE POPULATION MODELS WITH VARIOUS LEVELS OF FERTILITY AND MORTALITY AND TWO SCHEDULES OF MALE AGE-SPECIFIC ACTIVITY RATES

Gross reproduction rate	30 years expectation of life at birth		50 years expectation of life at birth		70 years expectation of life at birth	
	A	B	A	B	A	B
<i>Replacement rate (entrants less retirements and deaths) per 1,000 active males</i>						
4.0 .....	24.0	21.9	39.1	36.9	47.6	45.0
3.0 .....	14.1	12.2	28.8	26.9	37.4	35.6

Column B: Average age-specific activity rates for industrialized countries.

<sup>a</sup> Ratios rounded to the nearest multiple of 10.

analysing the changes in labour force cohorts according to age and sex at the two census dates.<sup>101</sup>

100. Effects of demographic factors upon the rates of labour force replenishment by entries from the inactive population, depletion by death, and depletion by retirement have been analysed by means of stable population models after the fashion described above regarding their influences upon crude activity rates. The results of this analysis of components of growth in the male labour

force, shown in table IX.11, again bring out the potent influence of fertility.

101. Lowering the gross reproduction rate from 3.0 to 1.0 under given conditions of mortality and age-specific activity rates reduces the rate of accretion by entries into the male labour force by one half or more in these models, while substantially increasing the rates of retirement and losses by death. Increased life expectancy, however, primarily affects the rate of depletion by death, while the effect of shifting from the average age-specific activity rates of agricultural countries to those of industrialized countries is mainly an increase in the rate of retirement. With the gross reproduction rate at 3.0, the replacement ratio ranges from 150 to 700 male entrants per 100 posts vacated by males, according to the combinations of mortality and specific activity rates; whereas with the gross reproduction rate reduced to 1.0, the pressure is greatly relaxed—indeed, reversed, as more posts are vacated each year than are demanded by new entrants.

<sup>101</sup> For examples of calculations along these lines referring to various countries, see: García and Castro, *República de Panamá, vol. 2: Proyección ...* (1965); Jaffe and Froomkin, "Economic development and jobs ..." (1966); Sadie, "Población y mano de obra ..." (1964); Jaffe and Carleton, *Occupational Mobility in the United States ...* (1954). In a number of demographic works, components of natural increase of the population in working ages have been calculated without reference to activity rates; such measures are less directly pertinent to the study of dynamics of labour supply. For examples, see Notestein *et al.*, *The Future Population of Europe ...* (1944); Bowles and Taeuber, *Rural Farm Males ...* (1956); Sadie, "Manpower resources of Africa" (1963); Taeuber, "Population growth in Latin America ..." (1962).

### 3. EXPECTATIONS OF EARNINGS AND CONSUMPTION

102. The economic consequences of the extensions of working life expectancy, and particularly the effect of increased longevity on earnings and consumption, have attracted the attention of a number of scholars. Tables of working life have been used in conjunction with data on annual earnings according to age and sex, to estimate the expectation of lifetime earnings of workers, or all persons, in each sex-age group. With estimates of the annual value of consumption according to age and sex (which is more difficult to measure), the expectation of lifetime consumption has also been computed. Thus the average net economic value, represented by the difference between expected earnings and consumption, can be calculated for males and females at each point in the life cycle, as well as the average cost of maintenance after withdrawal from economic activity and the average cost of bringing up and educating the annual crop of new entrants into the labour force. These calculations are pertinent to the study of such questions as the effects of changing activity rates and population structure upon the burden of dependency, the valuation of human capital, costs and economic benefits of migration considered as a transfer of human capital, and the costs of mortality considered as a human capital loss.<sup>192</sup>

103. Costs of mortality, reckoned in terms of the loss of investments in the upbringing of children who do not survive to maturity as well as the loss of the expected earnings of workers who die before retirement age, appear rather large in proportion to national income where mortality rates are high.<sup>193</sup> It seems that the reduction of these losses by decreasing death rates should be an economic boon for developing countries; but it has to be taken into account that decreasing mortality rates add to the inactive as well as the active years of life and that the additional adult survivors generate further growth in the child population.<sup>194</sup> As shown above, the effect is likely to be some increase in the ratio of dependants to the labour force if fertility remains constant. So, unless the improved chances of survival to adulthood and the lengthening of working life lead to enhanced quality in the labour force or in other ways to rising productivity, the effect on income per head is likely to be adverse. In a comprehensive assessment of the economic implications of decreasing mortality rates, the stimulus to growth in the labour force and its possible effect on the trend of output per worker also requires

consideration. These remarks also apply to the question of economic implications in the transfer of human capital between countries by migration.

### D. Economic structure of the labour force

104. The economic significance of the industrial structure of the labour force and its relationship to progress in technology, productivity and national output have long engaged the attention of scholars. As early as the seventeenth century, Petty observed the adverse effects of a maldistribution of the labour force characterized by an overloading in non-productive occupations. Adam Smith and some of his contemporaries strongly emphasized the economic and social consequences of the division of labour. In a longer historical perspective, Marx viewed the specialization and diversification of labour as important landmarks of progress. But it was only with the pioneering studies of Clark and others that the structure of the labour force was precisely defined and quantitatively analysed in terms of the numbers and proportions of workers in the principal sectors of the economy. Still more recent contributions, such as that of Fourastié, stressed the relationship of labour force structure to technological progress and increased productivity.

105. Three principal classifications of the economic characteristics of the labour force are currently used in census statistics: industry, referring to the function of the establishment or enterprise in which the individual works; occupation, referring to the type of work which he does; and status, of which the four primary categories are employees, employers, workers on own account, and unpaid family workers.<sup>195</sup> The composition of the labour force in terms of each of these classifications reflects an important aspect of structure of the economy, closely related to the level of a country's economic development and productive efficiency.

106. Industry, occupation and status are among the least reliably reported items in population census enumerations.<sup>196</sup> In addition to errors in the reporting of these items, the statistics are affected by errors in the reporting of individuals as economically active or inactive and by the variations in census definitions of the labour force, which bear unevenly on different industry, occupation and status groups. For example, where few of the women in farm households who take part in the farm work are reported as economically active, not only the size of the labour force is understated but also the shares of agriculture in the industry classification, of farm labourers in the occupation classification and of unpaid family

<sup>192</sup> For examples of calculations along these lines, discussions of the concepts and problems of measurement, and interpretations of the economic significance of results, see Valkovics, "Magyarország népességének ..." (1966); Lengyel and Valkovics, "Mennyit termel és fogyaszt ..." (1965); Schmücker, "Der Lebenszyklus ..." (1956); Dublin and Lotka, *The Money Value of a Man* (1946); Perroux, "Les coûts de l'homme" (1952); Weisbrod, "The valuation of human capital" (1961); Sauvy, *Théorie générale de la population*, vol. 1 ... (1963), chaps. 24-26; Růžicka, "Economic aspects of mortality rates" (1965); Gini, "Los efectos demográficos ..." (1946); and his "Apparent and real causes ..." (1948); Boldrini, *Demografia* (1956), chap. 7.

<sup>193</sup> However, the magnitude of such losses in proportion to annual national income has been exaggerated in some computations, as shown by Hansen, "A note on the cost ..." (1957).

<sup>194</sup> Singer, *International Development* ... (1964), pp. 80 ff.

<sup>195</sup> In addition to these three main classifications, various socio-economic classifications have been provided in certain censuses. These generally consist of broad-based categories or a combination of occupation and status criteria. See, for example, Benjamin, *Demographic Analysis* (1969), pp. 148-151.

<sup>196</sup> See the results of reliability tests of the reporting of these and other items in the 1950 census of the United States Bureau of the Census, *The Post-Enumeration Survey: 1950* ... (1960), pp. 18, 35-40. For a discussion of the effects of errors in reporting of industry, occupation and status, see United Nations, *Methods of Analysing Census Data* ... (1968), pp. 73-76.

workers and possibly own-account workers in the status classification.

107. Varying forms of the classifications, especially of industry and occupation, pose additional problems both in international comparisons and in historical studies of national statistics. Distinct concepts of industry, occupation and status were first introduced in the censuses of a few countries about half a century ago. The earlier practice, which persisted in the censuses of many countries until a much more recent time, was to mix these concepts in a single, confused classification with overlapping rubrics from which, at best, only approximate measures of a few industry and occupation groups could be extracted.<sup>197</sup> International standards for census classifications of occupation, industry and status have been developed since the Second World War<sup>198</sup> and progress has been made in improving the quality and comparability of these classifications in recent national censuses; but numerous deviations from the standards persist.<sup>199</sup>

### 1. REGIONAL VARIATIONS

108. In spite of the defects of the statistics, it is clear that the proportionate shares of industry, occupation and status groups differ in characteristic ways between regions and countries at different levels of economic and social development. In fact, the share of the labour force engaged in agriculture is so closely related to the level of economic development that it is often used as an approximate measure of the latter.

109. Estimates of the distribution of the world's working force by broad industrial sector in 1960 show about 58 per cent in agriculture, 20 per cent in industry and 22 per cent in services (table IX.12). The high concentration in agriculture and the comparatively minor role of industry reflect the fact that the majority of the world's population lives in the less developed regions.<sup>200</sup> The striking difference between the sectoral distribution of the work force in developing and more developed regions is also shown in this table; whereas the former regions have, on average, 73 per cent of their labour force working in agriculture, the figure for the latter regions is only 28 per cent. In both the developing and the more developed regions, the segment of the labour force in the service sector is somewhat larger than that in industry.

<sup>197</sup> It has been pointed out that clear-cut occupational classifications cannot accurately describe the economic activities of many persons in societies at an early stage of economic development where there is little specialization; Bauer and Yamey, "Economic progress and occupational distribution" (1951), p. 753; and their *The Economics of Under-developed Countries* (1957), pp. 33-40. See also chapter XIV.

<sup>198</sup> International Labour Office, *The International Standard Classification of Occupations* (1958); United Nations, *The International Standard Industrial ...* (1958); ———, *Handbook of Population ...* (1958), vol. 2. See also United Nations, *Application of International Standards ...* (1951).

<sup>199</sup> The variations of major group classifications of industry and occupation can be seen in the compilation of data from the most recent censuses in United Nations, *Demographic Yearbook, 1964 ...* (1965), tables 9-11. The status classifications (table 11) are seen to vary less.

SOURCE: Based on International Labour Office, *Labour Force Projections ...* (1971), part V, table 3.

Note: Because of rounding, parts do not in all cases add to exactly 100.

<sup>a</sup> Including agriculture, forestry, hunting and fishing.

<sup>b</sup> Including mining and quarrying, manufacturing, construction and electricity, gas, water and sanitary services.

<sup>c</sup> Including commerce, transport, storage and communications, public and private services.

110. Even wider differences are observed when the data for particular geographical regions are examined. In the most highly developed regions (Northern America, Northern and Western Europe and Australia and New Zealand) only 7 to 17 per cent of the labour force is engaged in agriculture and 36 to 45 per cent in industry. At the other extreme, in Africa, the percentage in agriculture runs as high as 84 to 87 per cent in the Middle and Eastern regions, and the industrial component amounts to only 5 to 7 per cent.

111. Among the more developed regions, Southern and Eastern Europe and the USSR are seen to have 42 to 43 per cent of their labour force still in the agricultural sector, a proportion which greatly surpasses that in Temperate South America and even slightly exceeds the figure for South Africa. The latter two

regions are, of course, well above the general level of development of the continents of which they are a part.

112. Aside from the Temperate region of South America, the rest of Latin America had just slightly more than half of its work force in the agricultural sector, according to the 1960 estimates. This is considerably less than the corresponding estimate for Asia (74 per cent in South Asia), but part of the difference may be due to the fact that few women are enumerated as unpaid family workers in agriculture in the former region. The very low percentage of workers in the industrial sector in South-East Asia (8 per cent) is particularly noteworthy, as it compares with 11 to 14 per cent in neighbouring regions.

113. The relatively high ratio of the services sector to the industrial sector in many of the developing regions is partly due to the historical role of these countries as exporters of primary products, a role which has led to the development of elaborate transportation and distribution networks to facilitate foreign trade.<sup>201</sup> Moreover, in some less developed regions the absence of sufficient employment opportunities in industry has led many persons to engage in low productivity service activities.<sup>202</sup>

## 2. CHANGES IN THE PROCESS OF ECONOMIC GROWTH

114. As discussed in detail in the introduction to chapter XIV, the process of economic growth is accompanied by profound changes in the structure of the economy, which is reflected, *inter alia*, in the corresponding structure of the labour force. With economic development, there is a movement of the labour force away from agriculture (at least in relative terms) and an increase in the proportion in secondary and tertiary activities. It is generally considered that once a certain stage of development has been reached, the share of the labour force in the secondary sector may stabilize or possibly even decline, while that of the tertiary sector continues to expand.

### (a) *Decrease in the share of agriculture*

115. Although there are imperfections in their quality, sufficient data are available for a number of countries to trace the typical patterns of change in the sectoral distribution of the labour force that have accompanied the process of economic growth.<sup>203</sup> One of the most

conspicuous features of these patterns, as mentioned above, is the decreasing proportion of the labour force engaged in agriculture. Clark observed from his analysis of available census data that "a high proportion of the total labour force engaged in agricultural and associated forms of employment is only to be found in economically underdeveloped communities, and that in an economically developed community there is almost invariably, through time, a tendency for this proportion to fall".<sup>204</sup>

116. Bairoch and Limbor have estimated that, for the developed countries as a whole, the share of the labour force engaged in agriculture declined from close to 60 per cent at the beginning of the century to about 30 per cent in 1960. For a group of more industrialized countries (excluding the countries of Eastern Europe and the USSR), the estimated percentage of the labour force in agriculture was 56 per cent in 1880, and had declined to 23 per cent by 1960. Moreover, the pace of the decline in these countries was found to have been accelerating throughout most of the period studied, having risen from 0.8 per cent per annum in 1880-1900 to 3.0 per cent in 1950-1960 and about 4 per cent between 1960 and 1967. In fact, the change that occurred in the 17 years between 1950 and 1967 was relatively as great as that in the 60-year period between 1890 and 1950.<sup>205</sup>

117. For certain industrialized countries the proportion of the agricultural labour force to the total can be traced back to very early censuses. In the United Kingdom (Great Britain), it dropped from about 35 per cent in 1801 to 5 per cent in 1961; in the United States of America, from about 75 per cent in 1800 to 8 per cent in 1960. In absolute numbers, the agricultural labour force reached its maximum during the 1850s in the United Kingdom and around 1910 in the United States of America; since those dates it has been approximately cut in half in both countries.<sup>206</sup> The decline in the absolute number of persons engaged in agriculture is a characteristic trend of developed countries. For the group of more highly industrialized countries studied by Bairoch and Limbor, the agricultural labour force fell from 84-85 million in 1900-1920 to 65 million in 1960.<sup>207</sup>

118. The basic causes of these trends are easily seen: with rising income and advancing technology in agriculture, the industrializing nations have been able to satisfy the relatively inelastic demands for agricultural products with diminishing proportionate (and eventually absolute) inputs of manpower in this sector, while rapidly growing demands for non-agricultural products

<sup>207</sup> Bairoch and Limbor, "Changes in the industrial distribution ..." (1968), p. 320.

have created an expanding market for labour in other sectors.<sup>208</sup>

119. In some less developed countries also, the proportionate share of agriculture in the labour force has been decreasing recently, but the trend has not been universal in the less developed regions of the world and, where it has occurred, the absolute numbers of the agricultural labour force have continued to grow rapidly, as a rule, owing to the rapid growth of the total population and the insufficient expansion of non-agricultural industries. Bairoch and Limbor's estimates for 1900 to 1960 for developing countries as a whole, while admittedly subject to many reservations, suggest that the agricultural segment has decreased from about 78 per cent of the labour force in 1900 to 71 per cent in 1960. The position of the developing regions in 1960 with respect to this indicator was comparable to that of the group of Western industrialized countries a century and a half earlier.<sup>209</sup>

120. In India, the proportion of agricultural and related workers in the total labour force has followed an irregular trend at the successive censuses since 1901 with little net change in the long run; the percentage was 72 in 1901 and 73 in 1961, according to figures adjusted for comparability.<sup>210</sup>

121. Estimates of trends in the period since 1950 have a sounder statistical basis than those for earlier periods, though for many areas they are still subject to considerable error. According to the latest estimates of the International Labour Office for the world as a whole, the proportion of the labour force working in agriculture declined from 61 per cent in 1950 to 58 per cent in 1960. This change resulted from a sharp drop—from 38 to 28 per cent—in the proportion in agriculture in the more developed regions, and a more modest decline from 79 to 73 per cent in agriculture in the developing regions. However, in the latter, the absolute numbers in the agricultural labour force increased by 77 million during this decade. For example, in Mexico, where the number of workers engaged in agriculture and related activities rose by 17 per cent between 1950 and 1960, the proportion of these to the total labour force shrank from 61 to 55 per cent.<sup>211</sup> An analysis of the male working force in Panama revealed a 20 per cent increase in the number in agriculture between 1950 and 1960, while the

proportion that these workers constituted of the total male labour force fell only from 59 to 58 per cent.<sup>212</sup>

122. In less developed countries, there has been relatively little, if any, push out of agriculture due to labour-saving technological improvements. The push has come rather from the accelerating growth of population and the labour force within the confines of a stationary or slowly advancing agricultural technology, in many cases with little scope for expansion by bringing additional land into use. The labour-absorbing capacity of non-agricultural industries also has been relatively small and growing only slowly in many less developed countries. Thus the shrinkage of the proportionate share of agriculture in the labour force, where it has occurred recently in less developed countries, has been less closely linked with economic growth than it was in countries now at higher levels of development.

123. As rapid a shift as possible of the preponderance of manpower from agriculture to non-agricultural industries is generally recognized as a necessary condition for satisfactory progress in raising levels of income per head in less developed countries. Indeed, it is often held to be a necessity for high-density agricultural countries to avoid any further substantial increase in absolute numbers of the labour force in agriculture, or even to decrease the numbers, if problems of agricultural underemployment are to be solved in the foreseeable future.<sup>213</sup> But it is difficult to achieve such objectives in the circumstances which are typical of less developed countries, while expanding agricultural production as needed to reach satisfactory levels of food consumption and without glutting the markets for labour in the little developed non-agricultural sectors. The greater the present share of agriculture in the total labour force and the higher the rate of growth of the total labour force, the more difficult it is to absorb all this growth in the non-agricultural sector and so to stabilize the number in agriculture.<sup>214</sup>

#### (b) *Changes in shares of non-agricultural industries*

124. According to Clark's well-known theory, as the share of agriculture and other primary industries in the labour force of a country undergoing economic development decreases, there is initially an increase in the share of secondary industries (manufacturing and construction) and, at a later stage, a greater expansion of the tertiary sector (transport, communication, trade, finance and other service industries).<sup>215</sup> Fourastié described

<sup>208</sup> This simplified statement requires qualifications with regard to the conditions of economic development in different countries and periods of time. See Kuznets, *Modern Economic Growth* ... (1966), pp. 100-114; Macura, *Stanovništvo i radna snaga* ... (1958); Valkovics, "Miért csökken ..." (1964); Hatai, "Keizai seicho to nogyo jinko" (1962); Frenkel, *Zatrudnienie w rolnictwie polskim* ... (1968).

<sup>214</sup> Dovring, "The share of agriculture ..." (1959). See also Jaffe and Froomkin, "Economic development and jobs ..." (1966), where the conditions required for holding the size of the agricultural labour force constant and for decreasing it by 15 per cent per decade are formulated mathematically in terms of the initial percentage of the labour force in agriculture, the rate of growth of the total labour force, and the rates of growth of productivity and total product in the non-agricultural sector.

<sup>215</sup> Clark, *The Conditions of Economic Progress* (1957), chaps. 9 and 10. See also the discussion in chapter XIV.

the transformation of labour force structure from an initial equilibrium characterized by the predominance of agriculture, through a transition period during which the primary sector steadily declines, the tertiary sector rises and the secondary sector, while at first increasing its proportion, later enters a period of stability and decline. Finally, in the future a new equilibrium is likely to be reached with both the primary and secondary sectors at a low level and the great preponderance of the labour force in the tertiary sector.<sup>216</sup>

125. Examining empirical data, Bairoch and Limbor found that, while the long-term trends in the structure of the labour force in the developed countries they studied fitted the pattern described by Clark fairly well, the stabilization in the manufacturing share which Clark had observed in the statistics available in the late 1930s was, in fact, only temporary, and a further rise occurred in this sector following the Second World War. These authors noted, however, that recent data for some highly developed countries suggested that a stabilization of the proportion in the manufacturing sector was likely in the medium term and a gradual reduction in the long run.<sup>217</sup>

126. Kuznets's comprehensive analysis of the sectoral distribution of the labour force included both cross-sectional comparisons for countries at different levels of development, as measured by income per head, and long-term trend data for twenty-eight countries. Using statistics from censuses taken around 1950, he found the following average percentage of industry groups in the labour force excluding unpaid family workers:

	Low-income countries	Medium- income countries	High-income countries
All industries .....	100.0	100.0	100.0
Agriculture, forestry and fishing	56.4	39.5	18.6
Manufacturing, mining and construction .....	17.6	25.5	37.8
Other industries, total .....	26.1	35.0	43.6
Other industries, total ...	100.0	100.0	100.0
Transport and communication	13.1	14.9	18.5
Trade and finance .....	25.0	27.7	30.7
Services .....	61.9	57.4	50.8

Note: Figures are unweighted means of percentages for countries in each income group.

As income rises, the relative rise in the secondary sector is seen to be greater than that in the tertiary sector, and this is true as income advances both from low to medium

<sup>216</sup> Fourastié, *Le grand espoir* ... (1963), pp. 131-148. Certain differences exist between the concepts of the sectors as defined by the author and those used by Clark. See *ibid.*, p. 83.

<sup>217</sup> Bairoch and Limbor, "Changes in the industrial distribution ..." (1968), pp. 320, 322. Vimont's analysis of the structure of the male labour force in several industrialized countries also showed a substantial rise in the secondary sector after the Second World War. See his *La population active* ... (1960), pp. 44, 46-47. However, a later study, which compared data for the mid-1950s and mid-1960s, found only a slight increase in the secondary sector, and a much greater expansion in the tertiary sector. Bloch and Praderie, *La population active* ... (1966), pp. 137, 150-151. See also United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1969, Part 1* ... (1970), pp. 122-124; Frejka, "Développement séculaire de la structure industrielle ..." (1966), pp. 6-7.

and from medium to high. While the share of the labour force in the tertiary sector shows less variation internationally than in the other two sectors, its composition varies considerably at different levels of development. In high-income countries, it contains proportionately more workers in transport, communication, trade and finance, while in low-income countries there are more in "other services", including domestic servants.<sup>218</sup>

127. From his study of long-term trends, Kuznets found that the rise in the share of the secondary sector was not as large, or as consistent, as might have been expected on the basis of the cross-section comparisons. This was partly explained by the fact that many of the countries studied were already fairly highly industrialized at the beginning of the period under investigation. Kuznets concluded that an upper limit was imposed on the share of the labour force in the secondary sector, possibly because rapidly rising productivity makes it unnecessary to divert an increasing share of manpower into this sector beyond a certain point.<sup>219</sup>

128. In a study of the labour force in metropolitan areas of countries classified by "development scores", Collver and Langlois found the following average percentage shares of industry sectors, using data from the censuses taken around 1950:

	Class III (least developed)	Class II (inter- mediate)	Class I (most developed)
Manufacturing .....	26	28	34
Commerce .....	19	20	20
Services .....	38	35	27
Other industries (including construction, utilities, transport and communication) .....	17	17	19

As economic development advances, some tendency towards an increase in the share of manufacturing and a decrease in the share of service industries in the metropolitan labour force is apparent in these figures. The authors of the study found, though, that regional variations among countries within each class were at least as great as the differences between class averages.<sup>220</sup>

129. Economic growth is not achieved merely by shifting manpower from one sector to another, but by raising

<sup>218</sup> Kuznets, "Quantitative aspects ..." (1957), part 2, pp. 23, 26-27; see also his *Modern Economic Growth* ... (1966), table 8.1 and pp. 106-107, 131-132.

<sup>219</sup> Kuznets, "Quantitative aspects ..." (1957), part 2, pp. 27-31. Fourastié's study of trends from the beginning of the twentieth century or earlier in a number of highly industrialized countries such as Belgium, France, Germany, the Netherlands, the United Kingdom (Great Britain) and the United States of America, showed that, as the agricultural sector declined in importance, the proportion of the labour force in the tertiary sector rose more than that in secondary industries. See his *Migrations professionnelles* ... (1957), pp. 90, 119, 150, 175, 255. See also the same author's *La civilisation de 1975* (1953), pp. 25-26. On the composition of the tertiary sector and its changes with economic development, see Lengellé, *The Growing Importance of the Service Sector* ... (1966), particularly pp. 26-31.

<sup>220</sup> Collver and Langlois, "The female labor force ..." (1962), table 3, p. 377. The "development scores" were based on measures of *per capita* energy consumption and percentages of male labour force in non-agricultural industries.

productivity in all sectors;<sup>221</sup> yet shifts within each sector from less productive to more productive lines of activity are an important feature of the growth process. In agriculture, there is a shift from traditional, subsistence farming to modernized and more specialized commercial farming; in manufacturing, from handicrafts and cottage industries to mechanized factories of increasing scale; in transport, from human and animal carriers to mechanized vehicles; in trade, from peddling and small-scale family store-keeping to more highly organized and specialized commercial enterprises; in service industries, from domestic and low-paid personal services to more lucrative business and machine-repair services and so on. In less developed countries, the push out of agriculture resulting from rapid population growth and the pressure of underemployment in that sector tends to inflate employment in the least productive segments of the secondary and tertiary sectors, which are relatively easy for displaced agricultural workers to enter, as they require little capital.<sup>222</sup>

### (c) Changes in occupational composition

130. Some of the kinds of changes in the occupational composition of the labour force which go with economic growth are illustrated by the following comparison of the relative size of certain major occupation groups shown by the 1960 censuses of Thailand, Spain and the United States of America, selected as examples of countries at relatively low, intermediate and high levels of economic development, respectively:<sup>223</sup>

	Thailand	Spain	United States of America
	(Percentage distribution)		
All occupations .....	100.0	100.0	100.0
Farmers, fishermen and hunters	81.9	39.8	6.3
Professional, technical and related workers .....	1.2	4.1	11.1
Administrative, managerial and executive workers .....	0.1	1.0	7.7
Clerical workers .....	1.1	5.8	13.6
Sales workers .....	5.4	6.2	7.6
Craftsmen, production process workers, and labourers not elsewhere classified .....	5.9	26.4	31.9
Other occupations and not classified .....	4.5	16.6	21.7

131. The major group, "farmers, fishermen and hunters", in the occupation classification parallels closely the

<sup>221</sup> *Ibid.*, p. 376.

<sup>222</sup> Compare Kuznets, "Quantitative aspects ..." (1957), part 2; and his *Modern Economic Growth* ... (1966), passages cited in foot-note 218 above; Sauvy, *Théorie générale de la population*, Vol. I ... (1963), chap. 9; Macura, *Stanovništvo i radna snaga* ... (1958).

<sup>223</sup> Computed from data in United Nations, *Demographic Yearbook, 1964* ... (1965), table 10, where the classifications of the national censuses have been adjusted to conform roughly to the international standard. For the present purpose, the data for the United States have been further adjusted, by reference to the census publications, so as to exclude armed forces and unemployed persons seeking work for the first time, and to make an approximate division between "administrative, managerial and executive workers" and "clerical workers", who are combined in the *Demographic Yearbook*. The latter adjustment was also made for Thailand.

trend of agriculture and related activities in the industry classification. As this group's share of the labour force decreases in countries undergoing economic development, the professional, technical, administrative, managerial, executive and clerical occupations are among the principal gainers. The percentage of these groups taken together is well over ten times greater in the United States of America than in Thailand. Large differences occur also in the shares of the blue-collar and manual occupations included under the headings of "craftsmen, production process workers and labourers not elsewhere classified" and "other occupations". The comparison masks differences in the composition of the latter groups, which are an important aspect of occupational upgrading in the course of economic development.

132. A comparative study of occupational trends in England and Wales since 1841, the United States of America since 1870, and in Australia and Canada since 1901 has shown a picture of more or less continuous large gains in the shares of the professional, administrative and clerical groups in the labour force. The total of white-collar occupations, including the group of sales workers (which showed generally less impressive and more regular gains) was found to have increased in England and Wales from 9.2 per cent of the labour force in 1841 to 29.7 per cent in 1951, in the United States of America from 10.4 per cent in 1870 to 42.2 per cent in 1960, in Australia from 20.7 per cent in 1901 to 28.0 per cent in 1947, in Canada from 15.2 per cent in 1901 to 38.3 per cent in 1961. These gains more or less balanced the losses of farming occupations in their proportionate share of the labour force, while the totals for blue-collar and service occupations followed various trends in the four countries.<sup>224</sup>

133. Within the blue-collar and service occupation groups, important changes have also taken place with economic progress. For example, the nature of changes in the composition of these groups in the United States during the first half of the twentieth century is indicated by the percentages of the total labour force in each group (figures are adjusted for comparability):<sup>225</sup>

	1900	1950
Craftsmen, foremen and kindred workers ....	10.5	14.1
Operatives and kindred workers .....	12.8	20.4
Service workers, except private household ....	3.6	7.9
Private household workers .....	5.4	2.6
Labourers, except farm and mine .....	12.5	6.6

### (d) Changes in status composition

134. The transition from the "atomized" organization of a little developed, predominantly agrarian economy made up chiefly of small, personal or familial units of production to the highly integrated structure of the modern industrial economy with its large-scale enterprises is reflected by a radical change in shares of status

<sup>224</sup> Farrag, "The occupational structure ..." (1964). The author stressed that, in view of the problems of achieving even rough comparability in the statistics, the figures should be taken as indicators of only broad orders of magnitude.

<sup>225</sup> Computed from data in Kaplan and Casey, *Occupational Trends* ... (1958).

groups in the labour force. Own-account workers and their unpaid family helpers, initially constituting the great majority of the labour force, are reduced to a minor fraction while a growing majority gravitates to the status of employees.<sup>226</sup> Again, the process is illustrated by a cross-sectional comparison of 1960 census statistics for three countries at different levels of economic development:

	Thailand	Spain	United States of America
	(Percentage distribution)		
All status groups .....	100.0	100.0	100.0
Employers .....	0.4	3.6	11.9
Own-account workers .....	29.5	18.6	
Unpaid family workers <sup>227</sup> ....	57.7	12.1	1.0
Employees .....	11.8	65.7	87.1
Not classifiable .....	0.7	—	—

135. Excluding unpaid family workers and considering the relative shares of other status groups in the labour force of countries at different income levels, Kuznets found the following average percentages of employers and own-account workers in the statistics of censuses taken around 1950:<sup>228</sup>

	Low-income countries	Medium-income countries	High-income countries
All industries .....	53	30	22
Agriculture, forestry, fishing ..	66	41	61
Manufacturing, mining, construction .....	31	21	11
Other industries .....	35	25	17

136. Apart from the influence exerted by the stage of economic development in shaping the status composition of the labour force, the social organization of production existing in a given country is also of importance. Given the same level of economic development, the status composition of the labour force may be entirely different

<sup>226</sup> See, for example, Fourastié, *Les 40,000 heures* (1965), pp. 71, 73; Bloch and Praderie, *La population active* ... (1966), pp. 121-124, 147.

<sup>227</sup> The very high percentage of unpaid family workers in the labour force as enumerated in the census of Thailand is due partly to liberal reporting of women in farm households as economically active. If the statistics for males alone are considered, the percentage of unpaid family workers is reduced to 35 in Thailand, 10 in Spain, and less than 1/2 of 1 per cent in the United States of America—still an impressive contrast. In the statistics for Spain, this category includes paid as well as unpaid family workers. While Thailand may be an extreme case because of the inclusion of so large a number of unpaid family workers, other countries at an early stage of development also show that own-account workers and unpaid family workers constitute a very high proportion of the labour force. For example, according to 1960 census data, nearly three fourths of the labour force in Ghana, and about two thirds in the Philippines, consisted of such workers. United Nations, *Demographic Yearbook, 1964* ... (1965), table 12.

<sup>228</sup> Kuznets, *Modern Economic Growth* ... (1966), table 8.1, p. 404. It has been shown that in a number of advanced countries, the proportion of the agricultural labour force consisting of employees has declined with increased mechanization and an over-all decline in agricultural employment. Thus, the trend in status composition of the agricultural labour force in these countries has been opposite to that of the non-agricultural labour force. United Nations, *Report on the World Social Situation* (1957), p. 95.

in a capitalist and a socialist country.<sup>229</sup> Not only may the proportions in the different major groups differ, but the groups themselves are different. In many socialist countries the group "employers" either does not exist at all or is very small; on the other hand, there exist important groups such as members of producers' co-operatives that are absent in capitalist countries. A comparison of the status composition of the labour force is shown below for Bulgaria, Hungary and Poland:<sup>230</sup>

	Bulgaria 1965	Hungary 1963	Poland 1960
	(Percentage distribution)		
All status groups .....	100	100	100
Employees .....	58.0	74.2	52.0
Members of agricultural producers' co-operatives .....	38.2	19.7	0.2
Members of handicrafts producers' co-operatives .....	2.4	2.5	2.3
Individual peasants .....	—	1.6	43.8
Handicraft workers not members of co-operatives .....	1.4	1.6	1.7
Others .....	—	0.4	—

137. The classification of status recommended for international use is likewise not always appropriate for the conditions prevailing in some developing countries. For example, in some Asian countries like India, employment relations in agriculture are sometimes so complicated and interwoven in peculiar forms of tenancy and mutual interdependence that they cannot be adequately described by the status classifications developed for use in industrialized countries.<sup>231</sup>

#### (e) Occupation-industry relationships

138. The occupation composition of the labour force depends partly on the industry composition, and vice versa, since some occupations are mainly or wholly confined to certain industries while others are found in varying proportions in different industries. The relationship between the occupational and industrial distribution of the labour force is likely to be modified in the course of economic development as a result of the increasing diversity of occupational specialization within industries reflecting the growing complexity of economic organization and technology.<sup>232</sup> Interrelationships also exist between the distributions of occupation and status and of industry and status.<sup>233</sup> Study of the occupation-industry relationships is especially valuable for gaining

<sup>229</sup> For a discussion of classifications by status in capitalist and socialist countries, see Boyarsky *et al.*, *Kurs demografii* (1967), pp. 84-86; Rodzyalovskaya, "The range and limitations ..." (1967), p. 388.

<sup>230</sup> Degtyar, *Trudovye resursy i ikh ispolzovanie* ... (1969), p. 46.

<sup>231</sup> For a discussion of such problems, see Thorner and Thorner, *Land and Labour in India* (1962).

<sup>232</sup> United Nations, *Methods of Analysing Census Data* ... (1968), p. 69.

<sup>233</sup> In the comparison of average percentages of employers and own-account workers cited above it was found that roughly one half of the difference between low-income and high-income countries could be attributed to the difference in industrial composition of the labour force. See Kuznets, *Modern Economic Growth* ... (1966), p. 419.

knowledge of the factors which affect employment opportunities in various occupations, including the effects of changing technology and shifting demand on the products of various industries. Estimates of future trends in employment according to occupation are commonly based at least partly on the study of these relationships together with anticipated changes in employment in various industries.

139. A change in the share of a given occupation in the labour force (or a difference in this share between two areas) can be considered as the sum of two components: (a) the effect of any change (or difference) in the distribution of the labour force among industries (called the "industry effect"); (b) the effect of any change (or difference) in occupational composition of the labour force within various industries (called the "occupation-mix effect"). For example, in the United States of America, where the share of professional workers in total civilian employment increased from 8.8 per cent in 1950 to 11.8 per cent in 1960, Gnanasekaran found that four fifths of the change could be attributed to the industry effect (especially the rapid growth of employment in professional and related service industries) and one fifth to the occupation-mix effect (especially the increasing share of professional workers in employment within manufacturing, professional and related service industries).<sup>234</sup> In a study of changes in the occupational composition of the Canadian labour force between 1931 and 1961, the industry effect was subdivided into two parts: (a) change in industrial distribution of total output; (b) change in productivity of labour within industries.<sup>235</sup>

140. Such analyses may be misleading unless it is noted that the occupational composition of the labour force and of employment is not determined merely by factors of demand but also by more or less independent supply factors, including, among others, the kinds and extent of education and vocational training which workers receive and their preferences for different kinds of work. Moreover, there is a certain inertia in the occupational structure, as various inhibitions to occupational mobility prevent swift adjustments to changing conditions of demand. The occupational composition of available manpower may influence occupation mixes in various industries, as the relative scarcity in the supply of workers qualified and willing to work at certain occupations may cause substitution of other occupations or of capital. The growth of industries may also be significantly affected by the conditions of labour supply in the occupations on which the industries depend. For example, in less developed countries, shortages of certain kinds of professional, technical, managerial and skilled manpower are among the major hindrances to the quick development of modernized manufacturing and other industries. The growth of such industries in economically more advanced countries has been facilitated by progress in education,

feeding the growth of labour supply qualified for professional, technical, managerial and clerical jobs.<sup>236</sup>

#### (f) *Processes of change in labour force structure*

141. Each occupation and industry group is replenished annually by a share of the workers entering or re-entering the labour force from the inactive population; is depleted by deaths and retirements; and gains or losses by the balance of workers shifting to and from other occupations and industries as well as by the balance of immigration and emigration. The study of these components of change is helpful in gaining insight into the influences of supply and demand factors and improving the basis for projections.<sup>237</sup> Research in this field has been concentrated chiefly on occupational mobility, including the changes in occupation which occur during the lifetime of individuals (intragenerational mobility) and the differences between the occupations of fathers and sons (intergenerational mobility, which is reflected in the changing occupational distribution of new entrants into the labour force).<sup>238</sup>

142. In the United States of America, the findings of a study of occupational trends since 1900 suggest that intergenerational mobility—the changing proportions of successive cohorts of workers entering each occupation—has played the leading role in bringing about major changes in the long run. Intragenerational shifts have also made significant contributions, though their directions in some cases have been opposite to the long-range trends of structural change. The professional group has gained consistently both by intergenerational and intragenerational shifts, and so has the group of craftsmen (with exceptions in some periods), while non-farm and farm labourers have lost consistently by both processes of occupational change. The share of farmers in the labour force has diminished progressively through intergenerational shifts but has been relatively little affected by intragenerational movements, as most men who became farmers have remained in this occupation until retirement. The group of operatives, on the other hand, has increased its share of the labour force by drawing in increasing numbers of young workers in successive generations, enough to over-balance constant losses by intragenerational shifts to higher paid occupations. The patterns in

<sup>236</sup> In this connexion, it should be noted that the relationships between educational attainments and occupational distribution of manpower vary greatly in space and time. For example, see Layard and Saigal, "Educational and occupational characteristics ..." (1966).

<sup>237</sup> Estimates of the components have been derived from cohort analysis of statistics from successive censuses giving cross-classification of the labour force by occupation or industry with age. See Jaffe and Carleton, *Occupational Mobility in the United States* ... (1954); Jaffe and Froomkin, "Economic development and jobs ..." (1966); Jaffe, "Economic development and the growth ..." (1966); Okazaki, *Rodoryoku no hendo to sangyokozo* ... (1965); Frenkel, "Wychodźstwo zawodowe ..." (1966).

<sup>238</sup> The information on these components is derived from sample surveys inquiring into the work histories of individuals and the occupations of their fathers. For examples, see Pourcher, "Un essai d'analyse par cohorte ..." (1966); Duncan, "Occupation trends and patterns ..." (1966); Blau, "The flow of occupational supply ..." (1965); Matras, "Some data on intergenerational occupational mobility ..." (1963).

<sup>234</sup> Gnanasekaran, *Interrelations Between Industrial* ... (1966), tables 1, 5, 8.

<sup>235</sup> Meltz, *Changes in the Occupational* ... (1965). An attempt was also made in this study to distinguish between changes in the shares of various occupational groups due mainly to supply factors and those due mainly to demand factors.

the managerial, sales, clerical and service occupations are not so clearly defined.<sup>239</sup> The patterns of both inter-generational and intragenerational mobility have changed in the course of time and their evolution shows the influence of varying conditions of labour demand. During the 1930s, when unemployment rates were high in the United States of America, the long-range trend of occupational upgrading appears to have been slowed and at some points temporarily reversed.<sup>240</sup>

143. Intragenerational mobility in occupation and industry varies greatly according to age. For example, in the United States of America during the 1940s, the estimated rate of occupational mobility (percentage of male workers in each age group at the beginning of the decade who shifted during the decade from one major occupation group to another) declined from a maximum of 21 per cent for the ages 15-19 and 20-24 years to 16 per cent for 25-29, and progressively lower in each succeeding age group up to 60-64 years, where the rate was estimated at 1 per cent.<sup>241</sup> This observation lends some support to the hypothesis that the aging of a country's labour force tends to impair the adaptability of the occupational and industrial structure to changing conditions of labour demand and thus to aggravate the risks of structural unemployment.<sup>242</sup>

144. On the other hand, the seeming advantage for flexibility of manpower utilization inherent in the youthful age composition and rapid growth of the labour force in less developed countries may be illusory. Potential flexibility on this account is of little avail where the shortage of capital, deficiency of technology, and other obstacles severely limit the rate at which shifts in the occupational and industrial distribution of employment can be accomplished. On the contrary, in those circumstances, the greater the number of young workers added annually in proportion to the size of the labour force, the more difficult it becomes to expand the proportionate share of employment in industries and occupations which have high productivity, and to prevent the accumulation of excessive labour supply in agriculture. The point is well illustrated by the following comparison of components of change in the male agricultural labour force of Panama and Japan during the decade of the 1950s (rates per 100 males in the agricultural labour force as of 1950):<sup>243</sup>

	Panama	Japan
New entries .....	44.4	16.6
Net mobility .....	- 9.0	- 21.5
Deaths .....	11.0	11.8
Retirements .....	3.5	5.2
Net growth .....	20.9	- 22.0

## E. Unemployment and underemployment

145. Waste of labour resources takes the forms of unemployment (that is, a complete lack of employment for a part of the labour force) and underemployment (that is, employment which is deficient in quantity or quality, so that it does not sufficiently occupy the worker's time and productive capabilities or so that it yields inadequate earnings). The level of unemployment and underemployment in a country is primarily determined by economic conditions, though demographic trends affecting the size and composition of the labour force also exert an influence. The theoretical aspects of the relationship between demographic factors and different types of unemployment and underemployment are discussed in chapter XIII, section C. In the present chapter, some findings of studies on the volume and features of unemployment and underemployment in different parts of the world are presented, including estimates of surplus labour in agriculture.

### 1. MEASURES AND LEVELS OF UNEMPLOYMENT

146. The enumeration of unemployed workers in a census or demographic sampling survey requires a criterion of availability for employment whereby the unemployed are distinguished from persons not in the labour force.<sup>244</sup> Although population censuses and demographic sampling surveys have gained ground during recent decades as primary sources of unemployment statistics in many countries, social security and other kinds of administrative records also provide data on unemployment and are the main source in some countries.<sup>245</sup>

147. Unemployment represents the difference between labour supply and demand, but the level of unemployment is also influenced by a variety of factors, such as institutions, attitudes and patterns of behaviour relating to the security of job tenure, to the spatial and occupational mobility of labour and to the propensity of unemployed persons to accept what employment they can get or to continue seeking jobs better suited to their qualifications, aspirations and tastes. The policies of Governments and the measures which they take to deal with unemployment problems may have much to do with

<sup>239</sup> Duncan, "Occupation trends and patterns ..." (1966), particularly table 6. The findings of Jaffe and Carleton, *Occupational Mobility in the United States* ... (1954), with reference to the decades of the 1930s and 1940s are broadly similar.

<sup>240</sup> Jaffe and Carleton, *Occupational Mobility in the United States* ... (1954); Duncan, "Occupation trends and patterns ..." (1966). See also Palmer, *Labor Mobility in Six Cities* ... (1954); Parnes, *Research on Labor Mobility* ... (1954).

<sup>241</sup> Jaffe and Carleton, *Occupational Mobility in the United States* ... (1954), table 9, p. 37. The estimated rates for the decade of the 1930s describe an age curve of similar shape but on a lower level. On age differences in rates of shifting of workers from agriculture to other industries in Poland, 1950-1960, see Frenkel, "Wychodźstwo zawodowe ..." (1966).

<sup>242</sup> Theoretical arguments, *pro* and *con*, relating to this hypothesis are summarized in Stassart, *Les avantages et les inconvénients* ... (1965), pp. 167 ff., with citations of the views of various authors.

<sup>243</sup> Jaffe and Froomkin, "Economic development and jobs ..." (1966), tables 3 and 4.

<sup>244</sup> On the criteria recommended by international bodies, see United Nations, *Handbook of Population* ... (1958), vol. 2. See also International Labour Office, *International Standardization of Labour Statistics* (1959).

<sup>245</sup> Unemployment measures derived from such records are affected by the restrictions of coverage of the administrative operations as well as by the regulations which govern the recording of an individual as unemployed, for example with regard to eligibility for compensation. The international comparability of such statistics is poor on the whole. For a discussion of different types of unemployment statistics, see International Labour Office, *Employment and Economic Growth* (1964), p. 14.

the levels of these rates. Another important factor is the form of the economic structure as reflected by the proportionate shares of employees and other status groups in the labour force. The risk of unemployment bears primarily on employees; in fact, unemployment statistics in some countries are confined to workers having the status of employees. Self-employed workers and their unpaid family helpers are more likely to be underemployed than to face complete lack of employment in adverse circumstances.

148. Some unemployment is considered practically unavoidable in an industrialized market economy, even though the demand for labour may exceed the supply, and a certain minimal rate of frictional unemployment is considered to be consistent with full employment.<sup>246</sup> If the labour force tends to swell when unemployment decreases,<sup>247</sup> the unemployment rate tends to understate the extent of employment expansion which would be required either to do away with unemployment or to reduce it to a level regarded as satisfactory.<sup>248</sup>

149. The identification and measurement of types of unemployment pertinent to the study of its causes and remedies are among the chief preoccupations of theoretical and pragmatic works in this field. The main categories of unemployment are generally identified and their definitions are discussed in chapter XIII, section C. Briefly, these include: frictional unemployment, seasonal unemployment, cyclical unemployment, structural unemployment and unemployment which results from a chronic deficiency of the total demand for labour in relation to supply. It may be noted that these different types of unemployment do not have the same relative importance for more developed and less developed countries. In the former, there is commonly cause for concern over cyclical instability and structural maladjustments related to automation and other technological changes, the obsolescence of industries and occupational skills, and the imperfect mobility of labour. In the less developed countries, the chronic deficiency of total demand for labour (or, in terms more appropriate to the conditions of less developed countries, the deficient volume of opportunities for productive work) is commonly a major problem, related to the shortcomings of technology, the lack of capital, the poverty of developed natural resources, and the rapid growth of the labour force.

150. The unemployment rate is considered an important economic indicator. It is defined as the percentage of unemployed workers in the labour force or in the total of the group to which the statistics refer. Average unemployment rates in eight industrialized countries during the period 1959 to 1963, based on statistics from various

kinds of sources adjusted to conform to the definitions used in the United States of America, were as follows:<sup>249</sup>

Canada .....	6.3	France .....	2.7
United States of America .....	5.8	Sweden .....	1.6 <sup>250</sup>
Italy .....	3.9	Japan .....	1.4
Great Britain ....	2.8	Germany (Federal Republic)	0.7

Several different patterns were distinguished in the trend of unemployment rates in industrialized countries in the period following the Second World War. In Canada and the United States of America there were marked cyclical fluctuations, and the level of unemployment in the 1960s was higher than that of the previous decade. In Austria, the Federal Republic of Germany and Italy, unemployment rates moved gradually downwards during the post-war period, while in another group of countries including Australia, France, Japan, the Netherlands, New Zealand, Norway, Sweden, Switzerland and the United Kingdom, unemployment rates showed little variation at a low level.<sup>251</sup>

151. Much higher unemployment rates than those of the 1960s were experienced in some industrialized countries during the economic depression of the 1930s. The rate in the United States of America is estimated to have reached a peak of 25.2 per cent in 1933; at the other extreme, it sank to 1.2 per cent as an average for the year 1944, under the pressure of extraordinary war-time labour demands.<sup>252</sup>

152. The sex-age composition of the labour force may also have some effect on the rate of unemployment. Other factors being equal, the greater the share of women in the labour force, the less unemployment is likely to be recorded, since women are more prone than men to withdraw into inactive status when they are out of jobs.<sup>253</sup> As noted previously, a large proportion of elderly workers in a country's labour force may aggravate the risks of unemployment associated with immobility in occupation and residence.<sup>254</sup> On the other hand, a large proportion

<sup>249</sup> Averages computed from annual rates shown in Neef, "International unemployment ..." (1965). See also Gendell, "International patterns of unemployment" (1968); Myers and Chandler, "Comparative levels of unemployment ..." (1962) and their "International comparisons ..." (1960); Galenson and Zellner, "International comparison of unemployment ..." (1956).

<sup>250</sup> Average of 1961-1963.

<sup>251</sup> International Labour Office, *Employment and Economic Growth* (1964), pp. 19-22.

<sup>252</sup> Lebergott, *Manpower in Economic Growth* ... (1964), table A-3, p. 512. For a comparison of unemployment levels in various Western countries, see Urlanis, *Naselenie mira* ... (1965), p. 162.

<sup>253</sup> See section B; also Wolfbein, "Gross change in unemployment 1957-1959" (1960); Kalachek and Westebbe, "Rates of unemployment ..." (1961), p. 345. Because of the tendency of women to drop out of the labour force when not employed, sex differences in recorded unemployment rates are likely to understate the relative vulnerability of women, as compared with men, to loss of employment. On variations of unemployment rates in the United States of America according to sex, age and other demographic characteristics, see Thurow, "The changing structure of unemployment ..." (1965); Hauser, "Differential unemployment and characteristics ..." (1957).

<sup>254</sup> Elderly workers are likely to have an advantage in job security on account of seniority, but when they lose their jobs they may be at a disadvantage in seeking re-employment as a result of employer

<sup>246</sup> See chapter XIII, section C.

<sup>247</sup> See the discussion in section B.

<sup>248</sup> Calculations of "corrected" unemployment rates intended to eliminate this understatement have been attempted in some studies. See, for example, Dernburg and Strand, "Hidden unemployment 1953-1962 ..." (1966).

of very young workers may make for a high incidence of another kind of unemployment, since it is generally found that the youngest age groups in the labour force are the ones which exhibit the highest unemployment rates.<sup>255</sup>

153. As mentioned elsewhere, levels of unemployment are related to the stage of industrial development and the proportion of the labour force which is composed of employees. Thus the fact that unemployment rates in recent years have been higher in the United States of America than in Japan, for example, is explained partly (though not mainly) by the larger share of employees in the United States labour force, which is related to the higher degree of industrialization and the smaller share of agriculture in the economy of the United States of America.<sup>256</sup>

154. In countries with a low level of industrialization, the problems of unemployment and underemployment are reflections of the poverty and low productivity to which these areas are subject.<sup>257</sup> Unemployment rates may be low in spite of wide gaps between the supply of labour and the volume of opportunities for productive employment, since what would be unemployment in a more industrialized economy is spread in the form of underemployment over a large number of workers. This substitution of underemployment for unemployment may result not only from the predominance of self-employed and unpaid family workers in the labour force but also from the low level of income and consequent pressure on breadwinners to be constantly engaged in work which will provide at least some means of support.<sup>258</sup> Yet high rates of unemployment are recorded in some less developed countries, particularly where there is a relatively large urban population or an important wage-labour sector in agriculture, as in Ceylon, for example, where 9.8 per cent of the rural and 14.4 per cent of the urban labour force were found to be unemployed in a survey conducted during the period 1959-1960.<sup>259</sup> The corresponding rates for India recorded in the eleventh and

discrimination in favour of younger men, as well as obsolescence of skills and educational handicaps. See Douse, "Discrimination against older workers" (1961); Sadie, "Discrimination against older workers in perspective" (1955); Ribas, "L'âge de la retraite..." (1961).

<sup>255</sup> While this observation suggests that a youthful age composition of the labour force might be conducive to a relatively high unemployment rate (see Barber, "Canada's unemployment problem" (1962), p. 96), it would be so only to the extent that the high unemployment rates in the youngest age groups reflect inherent difficulties in their absorption into steady employment and not merely that the young workers, on account of lack of experience and seniority, get a disproportionate share of the unemployment due to the relative deficiency of labour demand. For further discussion of the relation of age distribution to unemployment, see chapter XIII, section C.

<sup>256</sup> An assessment of some of the factors mentioned here and in the next paragraph, as partial explanations for differences between unemployment rates in the United States of America and those in several other industrialized countries, was attempted in Myers and Chandler, "Comparative levels of unemployment..." (1962).

<sup>257</sup> Coale, "Population and economic development" (1963), p. 65.

<sup>259</sup> International Labour Office, "A survey of employment, unemployment..." (1963).

twelfth rounds of the National Sample Survey were 6.0 and 7.4 per cent, respectively. The national unemployment rate estimated for the Philippines in November 1958 was 7 per cent, while that for Pakistan in 1955 was only about 3 per cent, though a rate of 10 per cent was found for large towns in East Pakistan. The low rate of only about 2 per cent estimated for Java and Madura in Indonesia in 1958 is attributable in part to the long reference period of one year,<sup>260</sup> since the longer the period, the fewer persons will be found having been without any employment. A compilation of statistics for ten Latin American countries around 1960 showed national unemployment rates ranging from 1.6 per cent in Mexico and 2.7 per cent in Argentina and Peru to 11.2 per cent in Panama and 13.7 per cent in Venezuela; and urban rates as high as 25 per cent in Peru and 28 per cent in Chile.<sup>261</sup> Despite rapid economic development, Puerto Rico has continued to experience an unemployment rate above 13 per cent throughout the 1950s. During this decade a number of developing countries in all regions reported increased numbers of unemployed.<sup>262</sup>

155. In most socialist countries, according to official information, the major problems of unemployment which existed under the former capitalist régimes were solved during the early years of socialist reconstruction and since then unemployment is said to have been nil.<sup>263</sup> In Yugoslavia, however, unemployment has remained a problem in spite of the change in the social organization of the economy. In 1968 it was estimated that 3.4 per cent of the total labour force, or 10.5 per cent of all those in the employee category, were unemployed.<sup>264</sup> While the

<sup>260</sup> International Labour Office, "Unemployment and underemployment in India..." (1962).

<sup>261</sup> Jones, "Underutilization of manpower..." (1968), table 2. See also Harewood, "Employment in Grenada in 1960" (1966).

<sup>262</sup> United Nations, *1963 Report on the World Social Situation* (1963), pp. 75-76. In Puerto Rico during the period 1951-1963, the unemployment rate was reduced only slightly in spite of the considerable expansion of industrial production and emigration, which syphoned off the greater part of the natural increase of the labour force. An analysis of this experience has pointed to the conclusion that rising wages and increasing efficiency in the use of labour in the expanding industrial sector tended to minimize the growth of employment and to perpetuate unemployment. In effect, it appears that much of the underemployment which existed previously in Puerto Rico was transformed into unemployment during this period; and it has been suggested that similar experiences might be in store for the future in less developed countries such as India. See Reynolds, "Wages and employment..." (1965); Jaffe, *People, Jobs, and Economic Development...* (1959), chaps. 5, 7, 9.

(1967); Paskhaver, "The rational utilization of rural manpower..." (1967); Sonin, "Manpower balance in the USSR" (1966). On the question of providing full and effective employment in socialist countries, see also Kabaj, "Racionalne zatrudnienie" (1965); Mikulsky, "Trudovye resursy..." (1967); Sonin, "Ratsionalnoe ispolzovanie..." (1966); Kudryavtsev, ed., *Ekonomika truda* (1967), p. 13.

<sup>264</sup> Wertheimer-Baletić, "Regionalni aspekt nezaposlenosti..." (1970), pp. 788-789. The author also estimated the rate of unemployment in a broader sense to include Yugoslav workers employed abroad. On this basis, the unemployed would have amounted to 5 per cent of the total labour force, or 15 per cent of employees, in 1968.

number of unemployed has varied at different periods, the main characteristics of the group have remained essentially the same, namely, a large proportion of first-job seekers, of unskilled workers and of women. The existence of unemployment in Yugoslavia is said to be closely related to the transfer of labour from agriculture, which suffered from overpopulation, and to structural changes in non-agricultural industries.<sup>265</sup>

## 2. MEASURES AND LEVELS OF UNDEREMPLOYMENT

156. Greater difficulties are involved in the measurement of underemployment than of unemployment. Even in defining the basic concept of underemployment and its various forms, there are difficulties which have not been fully resolved. An international group of experts identified two major categories: (a) *visible underemployment*, which involves persons involuntarily working for periods of work shorter than normal; and (b) *invisible underemployment*, which exists when a person's employment is inadequate in terms of abnormally low earnings or because his job does not permit the full use of his highest skills.<sup>266</sup>

157. Efforts to measure underemployment in population censuses and sample surveys have been confined for the most part to the visible type, although measures of invisible underemployment manifested by substandard earnings have also been attempted in some instances. The standards of full-time work and minimal adequate earnings adopted for the purpose of underemployment measures differ greatly in different countries. For example, the length of a normal work week has been defined in recent surveys as 25 hours in Malaysia, 30 in Indonesia and Guyana, 35 in Sweden, Thailand and the United States of America, 40 in Ceylon and the Philippines, 42 in China (Taiwan), and 45 in the Federal Republic of Germany. Different criteria of availability for additional employment are also used.<sup>267</sup> In some surveys, part-time workers are asked whether they are seeking work; in others, merely whether they want more work. The importance of the difference between the two questions is illustrated by the results obtained in the Philippines (survey of October 1962), where both were

asked; 12.6 per cent of employed persons were reported as having worked less than 40 hours during the reference week and wanting more work; 7.1 per cent of those were classified as seeking work and 5.5 per cent as not seeking work.<sup>268</sup>

158. It is obvious, in view of the variations in the definitions and scope of the measures, that much importance cannot be attached to comparisons of the amounts of underemployment reported for different countries. The reported figures make it all too plain, though, that the dimensions of underemployment in the less developed regions of the world are vast. In India, the national survey carried out during 1956-1957 showed 8.3 per cent of the urban and 12.1 per cent of the rural labour force to be visibly underemployed (working less than 42 hours during the reference week and available for additional work).<sup>269</sup> The corresponding measure for Ceylon obtained in the 1959-1960 survey, with 40 hours as the standard for a full-time week, was 18.8 per cent visibly underemployed in the labour force of the whole country.<sup>270</sup> In Panama, a 1963 survey limited to the non-agricultural labour force showed the visibly and invisibly underemployed combined amounting to 20 per cent of the total according to definitions of underemployment which were different for employees and for self-employed workers and were not applied to unpaid family workers.<sup>271</sup> In Greater Santiago, Chile, according to a 1962 survey, about 17 per cent of the male labour force was estimated to be underemployed.<sup>272</sup> In Colombia it was estimated that "invisible unemployment in the subsistence sector of agriculture and visible unemployment in the non-agricultural sectors" amounted to about one fifth of the labour force in 1963.<sup>273</sup> In Trinidad and Tobago, in a 1959 survey, while only 6 per cent of the labour force were reported as visibly underemployed (working less than 32 hours during the reference week and willing to work more), 44 per cent were classified as invisibly underemployed by a criterion of substandard earnings.<sup>274</sup> According to some estimates, underemployment has also affected as much as 40 per cent of the labour force in Barbados and Jamaica.<sup>275</sup> Underemployment exists in more than negli-

<sup>265</sup> Macura, *Stanovništvo i radna snaga* ... (1958), pp. 319-327; Mulina, *Nezaposlenost, uzroci i karakteristike* ... (1969).

<sup>266</sup> International Labour Office, *Report of the Meeting of Experts* ... (1963), para. 22. See also International Labour Office, *Concepts and Methods* ... (1963); Doctor, "Recent progress in underemployment ..." (1967); Myrdal, "A critical appraisal of ..." (1965); Islam, "Concepts and measurement of unemployment ..." (1964); Das Gupta, "An empirical approach ..." (1961); Jaffe, *People, Jobs, and Economic Development* ... (1959), appendix C. For a further discussion of definitions of underemployment, see chapter XIII, section C.

<sup>267</sup> Examples of definitions, scope, methods and results of inquiries on underemployment in various countries are compiled in: International Labour Office, *Selected Recent National Surveys* ... (1963). For additional examples of methodological variations, see International Labour Office, "Unemployment and underemployment in India ..." (1962); Islam, "Concepts and measurement of unemployment ..." (1964); Jaffe and Quesada, "Assessment of underemployment ..." (1967); Boutillier et al., *La moyenne vallée du Sénégal* (1962); France, Mission Economique Centre-Oubangi, *L'emploi du temps du paysan* ... (1961); Sylos-Labini, "Precarious employment in Sicily" (1964).

<sup>268</sup> There were as many persons reported as wanting more work and seeking work in the group having worked 40 hours or more as there were in the group having worked less than 40 hours. This observation underscores the point that the usual measures of underemployment do not represent shortcomings in relation to the total available labour supply, but only in relation to the specified standards of full-time work. It is also worth noting that many individuals may want less work than they actually put in; see Morgan, Sirageldin and Baerwaldt, *Productive Americans* (1966), chap. 7.

<sup>272</sup> Elizaga, "The demographic aspects of unemployment ..." (1967), p. 266. A 1958 survey of the same area had shown that one quarter of all male workers had an income lower than the legal minimum salary. *Ibid.*, p. 267.

<sup>273</sup> Zschock, *Manpower Perspective of Colombia* (1967), p. 47.

<sup>274</sup> Harewood, "Overpopulation and unemployment ..." (1960).

<sup>275</sup> United Nations, *1963 Report on the World Social Situation* (1963), p. 76.

gible amounts in some industrialized countries also, although it is overshadowed by unemployment. For example, in the United States on the average for the year 1965, for every three unemployed persons there were two visibly underemployed (involuntarily working less than 35 hours a week).<sup>276</sup>

159. By weighting numbers of visibly underemployed persons according to the amounts by which their working-time inputs fall short of the full-time standard, an underemployment rate is obtained which may be added to the unemployment rate so as to measure the total shortcoming in relation to the full-time employment of the whole labour force.<sup>277</sup> For example, this shortcoming was estimated at 33 per cent in the rural areas of Indonesia (1958).<sup>278</sup> The complementary index, of the extent of employment in proportion to a full-time equivalent for the labour force as a whole, was estimated in Senegal at 59 per cent for urban and 66 per cent for rural areas.<sup>279</sup>

### 3. ESTIMATES OF "LABOUR SURPLUSES" IN AGRICULTURE<sup>280</sup>

160. Instead of attempting to identify and count unemployed and underemployed individuals, one may approach the question in a different way by comparing a measure of available labour supply with an estimate of labour requirements. This approach has been taken mostly in studies of the utilization of labour supply in agriculture, although methods of macro-economic analysis have been devised for the global assessment of labour requirements and supply in an economy as a whole.<sup>281</sup>

161. The amount of labour required in agriculture under the conditions existing in a country at a given time depends on labour inputs per unit of land, livestock and the like, or per unit of product. Even if the norms for these inputs are founded on a thorough study of conditions and experience in the country concerned, they are essentially arbitrary, since they must refer to some specified level of efficiency among the different levels achieved on the country's farms. The higher this level is placed, of course, the smaller will be the estimate of labour requirements and the larger the estimated labour surplus. The norms which have been specified for various countries and time periods differ immensely. For example, in one study, norms for annual labour inputs in wheat production around 1960 were put at 260 man-days per hectare in Mediterranean areas with traditional farming,

91 days in Yugoslavia, and 10 days in the United States of America, and the figure for the United States of America as of 1910-1914 was put at 38 days.<sup>282</sup> The measure of available labour supply also depends on norms for annual inputs of labour per head of the population, which may be general averages for the agricultural population as a whole or specific figures for sex-age groups. These norms, too, are to some extent arbitrary although observed practices in farm households working under conditions considered to be satisfactory may be taken as a guide.<sup>283</sup>

162. The magnitudes of agricultural labour surplus estimates for various countries and time periods vary over a wide range. Such estimates are as a rule very rough and lack comparability, owing to the absence of satisfactory norms of labour requirements, as mentioned above. In one study of pre-war conditions in Eastern European countries, the surplus was found to be 22 per cent of the available agricultural labour supply in Hungary, about 50 per cent in Romania, Bulgaria and Poland, and nearly 73 per cent in Albania.<sup>284</sup> A surplus of 40 per cent was estimated for India as of 1960, and only 10 per cent for southern Italy as of 1952.<sup>285</sup> In the late 1950s the Food and Agriculture Organization of the United Nations (FAO) estimated that from 28 to 64 per cent of agricultural workers in various parts of the Middle East, North Africa and Southern Europe were surplus.<sup>286</sup> In more developed as well as less developed countries, such calculations have indicated the existence of sizable reserves of redundant labour supply in agriculture. In Denmark for example, the surplus was estimated at about one third of the available supply as of 1951 and, although the supply decreased by about one fourth during the next eight years, the amount of labour required in Danish agriculture decreased more, so that the proportion of excessive supply increased somewhat. Findings were generally similar with regard to other Western European countries and the United States of America.<sup>287</sup> Attempts to calculate labour surpluses in Polish agricul-

<sup>282</sup> Dovring, *Problems of Manpower* ... (1964), table 4, p. 42.

<sup>283</sup> On the methodological problems in such calculations, and ways of resolving them, see *ibid.*; also Communauté Economique Européenne, *Le chômage et la main-d'œuvre* ... (1965); Coutin, "Réflexions sur la population ..." (1964); dell'Angelo, *Note sulla sottoccupazione* ... (1960); Doctor, "Recent progress in underemployment ..." (1967), pp. 351-352. In some studies, attention has been directed more towards the size of agricultural population which could be supported on a country's land resources, and the question of overpopulation, than toward labour requirements and labour surplus. For example, see Issawi and Dabiezis, "Population movements and population pressure ..." (1951); Hayashi, *Results of an Investigation* ... (1949); Clark, "What constitutes rural overpopulation?" (1955).

<sup>284</sup> Moore, *Economic Demography of Eastern* ... (1945), pp. 63-64. Other authors have made different estimates; see Baum, *Population, Manpower, and Economic* ... (1961), pp. 7-8. Estimates of labour surpluses in Polish agriculture for the pre-war period varied greatly. For a critical survey of such estimates, see Stańczak, "Przeludnienie agrarne w Polsce ..." (1955).

<sup>285</sup> Sundaram, "Utilization of idle manpower ..." (1961); dell'Angelo, *Note sulla sottoccupazione* ... (1960).

<sup>280</sup> See also the discussion in chapter XIII, section C.

<sup>281</sup> For examples of the latter, see Correa, ed., *Technology, Employment, and Economic Growth* ... (1963); and his "A method for evaluating ..." (1964).

ture after the war have yielded substantially varying results.<sup>288</sup>

163. Many economists have called attention to the inadequacies of the methods used to calculate labour surpluses.<sup>289</sup> Such estimates may greatly exaggerate the quantities of manpower actually available in existing circumstances for transfer from agriculture to other employments. Commonly, much of the excess of agricultural labour supply over requirements is seasonal and there may be little or no excess over the requirements at

the seasonal peaks, even where a majority of the workers are idle during most of the year.<sup>290</sup> Moreover, it cannot always be taken for granted that labour inputs corresponding to the assumed norms would be forthcoming if ample opportunities for employment were present, nor that the norms for efficiency in the utilization of labour could be attained in existing circumstances on the less efficient farms. The estimates may represent to a large extent a technically possible rather than an actually existing surplus of labour, and the actual availability of the potential surplus may require profound changes in traditional technologies, ways of life and aspirations of the people.<sup>291</sup>

<sup>288</sup> Adamowski, *Ewolucja zatrudnienia w rolnictwie polskim* ... (1964), p. 357, foot-note 1. In the USSR, though certain areas suffer from agricultural labour shortages, others have labour surpluses; for example, in 1959 the surplus was estimated at about 28 per cent in the Ukraine and Moldavia, 42 per cent in Byelorussia, and as high as 99 per cent in Georgia. Moreover, it is reported that the surpluses in some of these areas increased during the next few years as the cohorts born during the years of highest post-war birth rates reached working age. See Perevedentsev, "Migratsiia naseleniia i ispolzovanie trudovykh resursov" (1970).

(1965); United Nations, Economic Commission for Asia and the Far East, "The supply of rural labour ..." (1964).

## FAMILIES AND HOUSEHOLDS

1. Demographers study population composition in terms of individual traits such as sex, age, labour force status, occupation, urban-rural residential groups etc., but this is an abstract and incomplete way of viewing the population. All human activities involve participation in groups, the single most important human grouping being the family or household. Unfortunately, so much of demography is focused on the study of individuals that the study of groups is comparatively neglected.<sup>1</sup>

2. Individuals and their personal characteristics serve as the statistical units for analysis of the sex and age structure of population and the process of population replacement. They represent the atomistic units of the society. On the other hand, families and households constitute its molecular units, which are of vital importance in many aspects of human life.<sup>2</sup>

3. It is through the family that each generation is replaced by the next generation. Through the family, children are brought into the world and cared for until they can assume their own responsibilities in society. It is also through the family that each generation fulfils a major portion of its responsibilities to the ill, the dependent, and the aged of the preceding generations.<sup>3</sup>

4. In addition, the household occupies a single housing unit and is therefore the most relevant population concept for use in analysis of housing trends and planning for future needs. The family or the household, and not the individual, is the primary unit of consumption used in various marketing and cost-of-living studies. The family or household as the unit of statistical enumeration is also central to the study of income maintenance, economic dependency, saving, fertility, migration, social welfare and social adjustment etc.

5. Trends and variations in the size and structure of families and households, their dynamic changes according to phases of the family life cycle and factors affecting them, constitute a comparatively new field of demography and have been treated relatively little in the literature. True, there is an enormous volume of sociological and anthropological literature concerning the family, some of which has relevance for demographic analysis.<sup>4</sup> But

most of these writings are non-demographic in nature and treat the family in terms of a small social group or a kinship network. Their authors, therefore, are mainly interested in the interpersonal, social-psychological relationships among the members of the family and in the functions of the family, particularly in respect of the importance of child-rearing and family problems such as parent-youth conflicts and family instability.

6. Although there have been a good number of studies in economics relating to average household size and household composition by size-class and by age of head, practically all of them regard the household factor simply as an independent variable to explain other economic variables.<sup>5</sup> In fact, only scattered efforts have been made to analyse variations of the size and structure of families and households and factors affecting them. The study of families and households, including that of marriage and divorce, is perhaps the most under-developed branch in demography.

7. One of the major contributions of demography to the study of families and households has been the development of the concept of "life cycle of the family" as a frame of reference, and a set of related definitions that facilitate comparable research internationally. The basic idea is that families go through a definite sequence of stages, and that at each stage the size and composition of the family undergo changes which have widespread social and economic effects in such areas as consumption and savings patterns, economic participation and social welfare and which call for adjustments on the part of individuals. The second important trend in the theoretical development of the demography of families and households is found in a series of studies on interrelationships between the changes in size and structure of the family and household and the demographic transition in the face of the processes of modernization, industrialization and urbanization. This involves studies of the relative importance of declining fertility and the trend towards "nuclearization" of families in bringing about the recent reduction in the size of household and family. The development of simulation models with the aid of computers—which permits the study of the effects of various demographic components, such as fertility, mortality, age at

<sup>1</sup> Bogue, *Principles of Demography* (1969), p. 367.

<sup>2</sup> Tachi, *Keishiki Jinko-gaku* (1960), pp. 247-251. The atomistic unit corresponds to the primary statistical unit and the molecular unit to the secondary unit in demographic statistics. See also Spiegelman, *Introduction to Demography* (1968), p. 1.

<sup>3</sup> Taeuber and Taeuber, *The Changing Population ...* (1958), p. 169.

<sup>4</sup> Among them, the studies made by George P. Murdock, Marion J. Levy Jr., William J. Goode, Talcott Parsons and Reuben Hill

are particularly pertinent for studies of demographic aspects of the family in view of their interesting conceptualization of the nuclear family, their interpretation of the family within the societal context and especially in relation to industrialization, urbanization and modernization.

<sup>5</sup> For example, see Prais and Houthakker, *The Analysis of Family Budgets ...* (1955); David, *Family Composition and Consumption* (1962).

marriage, pattern and timing of family fission, and the like, on family building—constitutes still another important trend.

8. The chapter first outlines in section A basic concepts and definitions of families and households which differ among countries and regions. Sections B and C summarize regional variations and trends, respectively, in the size and structure of families and households. Section D deals with the headship rate as an important measure of household formation and discusses its patterns by sex, age and marital status and regional variations. Section E is devoted to a summary of factors affecting the number and size of households and families, while section F briefly considers dynamic changes in the family and household structure from the viewpoint of the family life cycle.

### A. General definitions and concepts

9. As in many other areas of demography, data relating to families and households are affected by variations in definitions and concepts. Various publications of the United Nations have dealt comprehensively with concepts, definitions, and classifications of families and households used in the censuses of different countries.<sup>6</sup>

10. The concepts of the "family" and "household" are often confused because of their close relationship to each other and because of the lack of unambiguous definitions of either one of them. According to the United Nations *Multilingual Demographic Dictionary*, the household is a socio-economic unit, consisting of individuals who live together. On the other hand, the *Dictionary* defines the "family" primarily by reference to relationships which pertain to or arise from reproductive processes and which are regulated by law or by custom.<sup>7</sup> There is no uniform and universally acceptable definition of the family as a sociological-anthropological concept, partly due to differences in the structure and function of family organization existing in various parts of the world and partly due to many varieties of approaches and schools of thought conceived and worked out by different sociologists, anthropologists, social psychologists etc.<sup>8</sup>

<sup>6</sup> The following publications also present the internationally recommended standards for household and family statistics and treat problems in application of the standards in national censuses. United Nations, *Handbook of Population Census Methods*, vol. 3 ... (1959), pp. 67-68; United Nations, *Principles and Recommendations for the 1970 Population Censuses* (1969), pp. 14, 20-21, 24-25, 33-34; United Nations, *Principles and Recommendations for the 1970 Housing Censuses* (1969), pp. 20-21, 26-27 and 29-30.

<sup>7</sup> United Nations, *Multilingual Demographic Dictionary* ... (1958), p. 4.

<sup>8</sup> Reuben Hill and his associates classify various approaches to the study of the family within a sociological framework as follows: (1) the institutional approach, (2) the structural-functional approach, (3) the interactional approach, (4) the situational approach, and (5) the developmental approach. Under the first approach, the family is dealt with as an institution, which establishes the practices by which societies control the association of the sexes in marriage and family and sanction the reproduction and socialization of human generations. Under the structural-functional approach, "family" means the "nuclear family" made up of only husband and wife and their children, if any. This approach views the family as a social system, with constituent parts bound together by interaction and interdependence. The interactional approach describes the family as a unit of interacting personalities. It interprets family

11. According to Murdock, the family is a social group characterized by common residence, economic co-operation and reproduction. It includes adults of both sexes, at least two of whom maintain a socially-approved sexual relationship, and one or more children, own or adopted, of sexually cohabiting adults.<sup>9</sup> This definition, which embodies the concept of "nuclear family", has been the most widely cited definition in the sociological literature of the family, particularly in view of its emphasis on morphological characteristics of the family in terms of having a residential base and having its coherent members tied by blood, marriage or adoption.<sup>10</sup>

12. With regard to the basic notions of the family and household and their components, fairly substantial differences exist in the various censuses, despite the international recommendations in this field. The United Nations definition of household recommended for international use is as follows:

"The concept of 'household' is based on the arrangements made by persons, individually or in groups, for providing themselves with food or other essentials for living. A household may be either: (a) a one-person household, that is, a person who makes provision for his own food or other essentials for living without combining with any other person to form part of a multiperson household, or (b) a multiperson household, that is, a group of two or more persons who make common provision for food or other essentials for living. The persons in the group may pool their incomes and have a common budget to a greater or less extent; they may be related or unrelated persons or a combination of both."<sup>11</sup>

phenomena in terms of role playing, status relations, communication problems and the like. The situational approach also views the family as a unit of interacting personalities, but also as being subject to external stimuli which influence behaviour of family members. Finally, the developmental approach, too, views the family as a unity of interacting personalities, but its point of departure is the family life cycle or stages of development through which the family and its members travel. This approach deals specifically with the unifying theme of family change through the time dimension. See Hill and Hansen, "The identification of conceptual frameworks ..." (1960), pp. 299-311; Sirjamaki, "The institutional approach" (1964); Pitts, "The structural-functional approach" (1964); Christensen, "Development of the family field of study" (1964); Duvall, *Family Development* (1962).

<sup>9</sup> Murdock, *Social Structure* (1949). Murdock postulated that the nuclear family was universal and that it had four essential functions which it always and everywhere fulfilled. These four functions are: (1) socialization, (2) economic co-operation, (3) reproduction, and (4) sexual relations. *Ibid.*, pp. 4-11.

<sup>10</sup> For example, Levy's recent work is concerned with the residential family—that is, a group of persons usually related by blood or marriage, living together in a common residence or dwelling. Therefore his generalizations may not be taken to apply to family and kinship units defined in terms of interaction or reciprocal obligations among kin living in different households. See Levy, "Aspects of the analysis ..." (1965).

<sup>11</sup> United Nations, *Principles and Recommendations for the 1970 Population Censuses* (1969), p. 14; ———, *Principles and Recommendations for the 1970 Housing Censuses* (1969), pp. 21, 29-30. Households usually occupy the whole, part of, or more than one housing unit, but they may also be found in camps, in boarding houses or hotels, or as administrative personnel in institutions, or they may be homeless. Households consisting of extended families which make common provision for food, or of potentially separate households with a common head, resulting from a polygamous union, may occupy more than one housing unit.

13. On the other hand, the family is defined in United Nations recommendations as follows:

"The family is defined as those members of the household... who are related, to a specific degree, through blood, adoption or marriage. The degree of relationship used in determining the limits of the family is dependent upon the uses to which the data are to be put and so cannot be precisely set for world-wide use."<sup>12</sup>

14. The term "family" may also refer to the "extended family" or "joint family" which would include, in addition to a couple with their minor children, their married children and their families and other relatives as well. This type of family is often found in countries with a predominantly rural economy, though it is not as common as is sometimes assumed. Such a family may be scattered or may live together and share a housing unit. For statistical purposes, it would not be practical to deal with the "family" in this wider sense of including persons tied to each other by kinship but residing in different households. Therefore, in conformity with the United Nations definition, the family can be interpreted in a limited sense as a group of two or more persons mutually related who live together and share the same housing unit.<sup>13</sup>

#### B. Regional variations in the size and structure of families and households

15. The term "size of household" is fairly unambiguous, but the term "size of family" is commonly used in two different ways. In the literature on fertility, it usually refers to the number of children ever born alive; the unit of measurement may be a married couple, a woman in her current marriage, or an ever-married woman. For a woman who has passed her reproductive period, the number of children she has borne is sometimes called her "size of completed family". In the literature on family composition, the term "size of family" generally refers to the number of persons who are related to each other and who live together, including adults as well as children.<sup>14</sup> According to the current United Nations

<sup>12</sup> United Nations, *Principles and Recommendations for the 1970 Population Censuses* (1969), p. 20. A family cannot comprise more than one household; a household can, however, consist of more than one family, of one family together with one or more non-related persons, or entirely of non-related persons. In practice, most households are composed of a single family consisting of a married couple without children, or of one or both parents and their unmarried children.

<sup>13</sup> The joint or composite family generally consists of more than two generations of a biological family and is found in countries where it is not the custom for children to leave the parental home on marriage. United Nations, *Multilingual Demographic Dictionary* ... (1958), p. 6. Generally, sociologists, anthropologists and social psychologists have emphasized interactional, institutional, functional and social psychological aspects of the family within a society, so that its scope is much broader than and somewhat different from this statistical approach. To those social scientists, especially family sociologists, the family is a form of social organization and institution through which a baby grows up, develops his personality and acquires socialization. Therefore, the family's scope of activities and influences, and its implications are far greater than those of the censal "family household". For the sociological literature, see, for example, Kirkpatrick, *The Family as Process* ... (1963); Sussman, ed., *Sourcebook in Marriage* ... (1963).

<sup>14</sup> Glick, *American Families* (1957), pp. 29-30.

recommendations, a family must include at least two mutually related persons.<sup>15</sup> In this chapter, the term "size of family" is used as a measure of family composition rather than that of fertility. Since statistical data on families are relatively scarce, the present chapter is devoted mainly to analyses of the size and structure of households.

TABLE X.1. ESTIMATED AVERAGE HOUSEHOLD SIZE FOR MAJOR AREAS AND REGIONS OF THE WORLD: 1965

Major areas and regions	Average household size
World total .....	4.54
Developing regions .....	5.22
More developed regions .....	3.54
Africa .....	4.99
Western Africa .....	4.94
Eastern Africa .....	4.93

SOURCE: United Nations, *Demographic Yearbook*, 1955, 1962, and 1963. The data for the countries which were not listed in the above United Nations yearbooks are taken from individual population censuses. United Nations, *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

<sup>a</sup> Excluding countries having fewer than 100,000 inhabitants and those having no satisfactory data.

America (5.09), East Asia (5.08) and Africa (4.99). Among the developed regions both Western Europe and Northern Europe show very low figures of 3.03, respectively.

17. The countries with average household size above 4.5 are found almost exclusively in the developing regions of Asia, Africa, Latin America, and Oceania, excluding Australia and New Zealand. In addition to the latter two countries, the countries with average household size below 4.0 are located mainly in Northern America and Europe. As shown in table X.2, among thirty-three European and Northern American countries, only seven countries had a household size larger than 4.0 around 1960. In Europe, Albania had an average household size of 5.8, which is extraordinarily large, even by inter-regional standards. In Asia, some Middle Eastern countries, namely Cyprus and Israel, have relatively low average household sizes of 3.96 and 3.83 respectively. In Latin America, Argentina and Uruguay in the Temperate region have an average household size of less than 4.0 persons, and seven out of ten Caribbean islands for which data are available indicate a figure between 4.0 and 4.5. In Africa, out of nineteen countries, eight show average household sizes smaller than 4.5 and two countries—Central African Republic and Gabon—report a size even smaller than 4.0. Some of these figures are considered to be somewhat dubious, however, perhaps due to vague census definitions of household and family and defective census results.<sup>17</sup>

18. In addition to the United Nations analysis, international comparative studies have been made by Burch and Bogue. Burch undertook a pioneering work in 1967, using data published in United Nations *Demographic Yearbooks* as well as more detailed census materials from selected countries, mostly in Latin America.<sup>18</sup> His main

purpose was to test the recent hypotheses of Levy regarding the essential similarity of family structures, including average size of families in all societies.<sup>19</sup> He also examined the conventional notion that extended families are prevalent in rural-agricultural societies and over time industrialization and urbanization bring about their breakup into nuclear families and non-family households. The findings showed that the extended family is surprisingly less frequent than is commonly expected in pre-industrial societies of the contemporary world. Burch concluded that the most striking feature of the frequency distributions of the data on average household size for the sixty-four countries in his study was their limited range. The vast majority of nations have averages falling within the range of three to six persons, only three cases in his study falling beyond these limits.<sup>20</sup> Burch's study substantiated Levy's broad sociological-demographic proposition that the general outlines and nature of actual family structures have been virtually identical in certain strategic respects in all known societies in world history for well over half of the members of these societies.<sup>21</sup> Backed by the empirical data, Burch pointed out that in no society has the very large residential family become the modal form.<sup>22</sup>

19. As shown in table X.2, in the United Nations study, only nine of 114 countries were found to have an average household size outside the limits set by Burch. As also indicated in Burch's study, notably absent are countries with the average household size which might be expected if ideal extended family patterns were adopted as a matter of course in any of the nations represented. Extended families of large size were thought to be typical of devel-

<sup>19</sup> Levy, "Aspects of the analysis . . ." (1965).

<sup>20</sup> Burch, "The size and structure . . ." (1967). See particularly p. 353.

<sup>21</sup> Levy, "Aspects of the analysis . . ." (1965), pp. 41-42. According to Levy, these strategic respects have to do with the following factors: (a) size of membership, (b) age composition and relationship of the membership through time, (c) composition by sex, (d) generational composition, (e) number of marital pairs, and (f) number of siblings.

<sup>22</sup> Burch, "The size and structure . . ." (1967), p. 34.

<sup>17</sup> For example, African censuses show wide fluctuations with respect to the percentage of one-person households. See United Nations, *Manual VII: Methods of Projecting Households and Families* (1973), p. 12.

<sup>18</sup> Burch, "The size and structure . . ." (1967).

oping nations such as India and Pakistan, traditional China and Tokugawa Japan, but Levy regarded such beliefs and expectations as largely pertaining to ideal types and he distinguished them from actual realities.<sup>23</sup>

20. Family sociologists have generally held the view that a close inverse relation exists between the level of industrialization and urbanization on the one hand, and the incidence of the "extended family" system, on the other. Furthermore, extended families are believed to be much more prevalent in rural than in urban areas. It is maintained that as a society develops, the extended family tends to be replaced as a modal form by the independent nuclear (or conjugal) family consisting of husband, wife, and children, if any.<sup>24</sup>

21. Since extended families were known to be prevalent in rural, pre-industrial societies, it had been assumed that family size in those societies was substantially larger than that in the developed countries, not only because of their higher fertility and subsequently larger number of living children, but also because of the doubling-up of nuclear families within the extended families. The typical residential family in non-industrial societies was seen as being large and complex, containing representatives of three or more generations, more than one nuclear family, and perhaps several collateral relatives. The favourite example of such a family system is that of traditional China, where all males in a direct line of descent, together with their wives and unmarried daughters, were supposed to occupy a common household, forming a social and economic unit under the authority of the oldest able-bodied male, the patriarch. The implied size of such a family group is large, perhaps ten persons or more on the average.<sup>25</sup>

22. More than twenty-five years ago, Hsu and Lang respectively questioned whether such a family was frequently found in practice. They argued that economic limitations, among other things, prevented all but the fairly well-to-do from actually maintaining such large households.<sup>26</sup> The masses in traditional China were

presumed to have lived in residential families closer in size, if not in all other respects, to those found in modern Western societies.<sup>27</sup> In Sjöberg's study it was pointed out that in pre-industrial societies, the extended family was more common in urban than in rural areas.<sup>28</sup> Also Levy argued that, because of economic or demographic limitations, in no society has the extended family become predominant in actual practice.<sup>29</sup> Goode further pointed out that such extended families require considerable managerial skills and leadership which are rather difficult to find and stresses and strains may occur and eventually lead to break-up of the family in cases where the formal leader and the ablest family member are not the same person.<sup>30</sup> Levy's viewpoint is that the "nuclear family" may not be the universal one in all societies, as Murdock or Parsons suggested,<sup>31</sup> but he argued that although ideal structures of the family vary considerably from one society to another, the actual family size, generational composition etc., vary much less than ideal types.<sup>32</sup>

23. On the basis of empirical research, a good number of demographers and family sociologists have agreed that the extended or joint family is an ideal or polar type,<sup>33</sup> though it is not the most frequent. For example, Goode commented that the belief that the Arab family is extended may be accepted as a description, not of reality, but only of ideals. He also observed that in the urban setting in Sub-Saharan Africa, housing facilities are in such short supply that very large households are difficult to arrange.<sup>34</sup>

24. Relatively modest sizes of household have been reported in surveys carried out in different parts of Africa. For the Union of South Africa, Hellman reported that in the recent Keiskammahoe survey, the household averaged 5.95 persons. The Orando survey showed an average of 5.38 and another survey taken in Springs found an average of 5.02 persons.<sup>35</sup> According to a survey in the eastern part of Sierra Leone, average household size was 5.4 persons.<sup>36</sup>

<sup>23</sup> Levy, "Aspects of the analysis ..." (1965), p. 49.

<sup>24</sup> Burch, "The size and structure ..." (1967), p. 347. For typical statements of this classic view pertaining to the relation between industrialization and family, see Kirkpatrick, *The Family as Process* ... (1963), pp. 137-139; Kephart, *The Family, Society* ... (1966), pp. 58-60; Davis, *Human Society* (1949), pp. 414-418. Noting that the conjugal type of family or organization had become generally dominant throughout Western civilization, Kephart (p. 60) noted that: "Despite the apparent stresses and strains involved, the conjugal family system seems to be the one most compatible with modern society. If the trend toward urbanism, industrialism, and mobility spreads to other parts of the world, it is just possible that the consanguine type of family organization will tend to disappear—along with polygamy". Davis (p. 418) observed that: "Marriage became increasingly a private matter beyond the control of the parents, and each new family unit tended to be independent of its predecessors. With the decline in mortality, fertility also declined. The small family, occupying its own small living space and moving as a free unit, became the dominant pattern. This small family system originated in Western industrial civilization and is now being diffused, along with other features of industrialism, to the rest of the world. It seems likely that eventually the whole of mankind will have a family organization roughly similar to that found in the United States today."

<sup>36</sup> Little, *The Mende of Sierra Leone* ... (1951), pp. 65-66.

25. It has also been shown that household size in India was smaller than generally thought. Dandekar and Unde observed that no census data support the widespread notion that the joint family was a rule in the Indian society in the past and that it was giving way. In fact, more than 77 per cent of the households sampled in the State of Maharashtra were only one-couple or non-couple households.<sup>37</sup> Industrialized countries, on the other hand, did not have such large household size in the past as was commonly believed.<sup>38</sup>

26. Bogue observed that while the so-called "extended family", where three or four generations live together under one roof or within one compound, is a part of the cultural standard of many countries, particularly in South Asia and East Asia, it occurs in fact primarily among the upper and upper-middle classes. Although there may be elaborate patterns of mutual aid and family solidarity extending over larger kinship groups, where this exists, it is primarily an interhousehold, and not a single residential unit, arrangement. The joint family as described and discussed in the literature of family sociology and cultural anthropology appears to be more a sociological tradition than a statistical reality.<sup>39</sup>

27. It is also of considerable demographic interest that in Burch's study, as well as in the United Nations study, the distribution of average household size is bimodal, suggesting that despite the limited range, there are two basically different groups of countries as regards household size, namely those with averages between 3 and 4 and those with averages of 5 or more (table X.2.). If the distinction is made between the developed and the developing regions according to the conventional dichotomy adopted by the United Nations, each of the subgroups shows a smoother normal curve than when the two subgroups are combined, the lower tail of the developing group and the upper tail of the developed group being overlapping to some extent. Interregional variations generally follow respectively the developed and developing group patterns. While the frequency distribution for Latin America exhibits a rather complex pattern, those for African and Asian countries are fairly normally distributed over higher size classes and those for European nations are normally distributed over lower size classes.

28. Burch pointed out that the occurrence of a bimodal distribution in this context is particularly interesting in the light of the similar but even stronger bimodal pattern that appears in distributions of countries by current fertility level (gross reproduction rate or crude birth rate).<sup>40</sup> In the United Nations study of world fertility levels around 1960, two groups of countries are clearly distinguished: a high-fertility group and a low-fertility group, with remarkably few countries on the borderline between them. The distributions for the world as a whole are strikingly bimodal.<sup>41</sup>

29. Such an observation leads to an inference that relatively high average household sizes in developing countries may be due in large part to their high fertility rather than to the extension of residential families. Of course, unlike the gross reproduction rate, the average size of household as an index is not free from the effects of changes and variations in age structure and it must be considered whether the developing countries have age structures contributing to somewhat larger household size than the developed countries, other things being equal. Various factors affecting the size and structure of families and households, including changes in age structure, are examined in section E.

### C. Trends in the size and structure of families and households

#### 1. MULTIPHASIC CHANGES IN STRUCTURE

30. Several salient features, patterns and trends have been noted in the demographic and sociological literature with respect to changes in the size and structure of families and households. Although irregularities and reverses are found in specific cases, the general trend is unmistakably in close association, or parallel with the long-range process of demographic transition in the face of modernization, industrialization and urbanization. Indeed, such secular family changes could not have occurred except in the context of societal modernization, although recently some students of these phenomena have pointed out that such a general interpretation of this relationship has sometimes led to over-simplifications.<sup>42</sup>

31. More specifically, certain characteristic features of households may be distinguished for each of the two major stages of demographic transition, namely (a) the stage of declining mortality, whether rapid or moderate, combined with relatively constant and very high fertility, and (b) the stage where a substantial decline in fertility has been attained and mortality shows further slow decline. Regarding stage (a) in which most developing countries of Africa, Asia and Latin America now find themselves, prominent features are likely to include:

- (1) Moderate increases in average size of household and family,
- (2) Moderate increases in relatively large-size (six persons or more) households and families and moderate decreases in relatively small-size households and families, with say, three persons or less,
- (3) Very small increases or stability in the proportions of heads of households for the different sex and age groups, and
- (4) Small increases or stability in the proportions of nuclear families and moderate increases in the proportions of one-person households in many countries.

<sup>37</sup> Dandekar and Unde, "Inter-state and intra-state differentials ..." (1967), p. 326.

<sup>38</sup> Laslett, "Size and structure of the household ..." (1969).

<sup>39</sup> Bogue, *Principles of Demography* (1969), pp. 369-370.

<sup>40</sup> Burch, "The size and structure ..." (1967), p. 353.

<sup>42</sup> For example, see Goode, *World Revolution and Family Patterns* (1963); Bell and Vogel, *A Modern Introduction to the Family* (1968), pp. 2 and 7; and Burch, "The size and structure ..." (1967), pp. 347-348.

32. On the other hand, developed countries which have completed stage (b) have been characterized by more distinct and sweeping trends. These include:

- (1) General secular decline in average size of household and family,
- (2) Increases in the proportion of small-size households and families, with, say, three persons or less, and decreases in large-size households and families, say, six or more persons,

- (3) Over-all increases in proportions of heads of households specific for sex and age, except in some middle-aged groups among females, and
- (4) Increases in the proportion of nuclear families and one-person households and decreases in the proportion of multi-generational extended families.

33. The above-mentioned features are only different facets of the dynamic process taking place in families and households as multiphasic responses to a changing

TABLE X.3. TRENDS OF AVERAGE HOUSEHOLD SIZE AND GROSS REPRODUCTION RATES IN TWELVE SELECTED COUNTRIES

United Kingdom (England and Wales)			United States of America			Canada

SOURCES: In general, household and population data were taken from the population and housing censuses of each country. Data on household size for the United Kingdom (England and Wales) are from Laslett, "Size and structure of the household ..." (1969); Nixon, "Size and structure of the household ..." (1970); Laslett, "The decline of the size of the domestic group ..." (1970). United States data on the average size of household from 1790 to 1950 inclusive are taken from United States, Bureau of the Census, *Historical Statistics of the United States* ... (1960), p. 16. Generally, gross reproduction rates are from United

Nations, *Interim Report on the Conditions and Trends* ... (1972). Gross reproduction rates for 1965 and 1966 are from United Nations, *Demographic Yearbook, 1969* ... (1970), table 31. For the United Kingdom for 1851 to 1881, reproduction rates are from Wrigley, *Population and History* (1969), p. 195. The Japanese reproduction rates were obtained from Institute of Population Problems, *Selected Statistics* ... (1970), p. 3.

\* For 1937.

configuration of demographic, economic and social factors.<sup>43</sup> These features are by no means mutually exclusive, but are rather interlocked with each other. In this section, trends in household size are discussed while other aspects of household change are considered in the following sections.

## 2. SECULAR CHANGES IN AVERAGE SIZE AND STRUCTURE

34. Table X.3 shows historical trends in average size of households and families for the twelve countries for which the pertinent data are available, at least from the beginning of the twentieth century.<sup>44</sup> As the table shows, data for a few of these countries are available even from the beginning of the nineteenth century.<sup>45</sup> Data for all of these countries, except India, show persistent and very remarkable secular declines in average household size for periods of more than fifty years or more. While these eleven countries are all economically developed, India, which belongs to the group of less developed countries, has shown no significant decrease in household size during the past sixty years, since population census taking was initiated in that country.

35. The general trends of declining average household size are considered to be parallel to the secular declines in fertility, and broadly in association with the global process of industrialization and urbanization,<sup>46</sup> though sudden or short-term fertility changes are not necessarily and immediately reflected in changes in household size.

<sup>43</sup> On the concept of multiphasic response, see Davis, "The theory of change and response ..." (1963).

<sup>44</sup> They are the United Kingdom, the United States of America, Canada, the Federal Republic of Germany, Belgium, Sweden, Japan, France, the Netherlands, Denmark, India and Yugoslavia, listed in order according to the number of years for which the data are available.

<sup>45</sup> Six countries, namely, the United Kingdom, the United States of America, Canada, Belgium, Sweden and the Federal Republic of Germany show trends for more than 100 years.

<sup>46</sup> This point is further elaborated later in this section.

In most situations, the decline in average size of household accompanied fertility decline, but in a minority of cases the household size decline lagged a few decades behind the onset of substantial fertility decline, as in the United Kingdom before the twentieth century and Japan before the Second World War. Conversely, short-term fertility increases have not been followed by increases in household size as seen in the United Kingdom, the United States of America, Canada, the Federal Republic of Germany, Sweden and France in the post-war years.

36. The data on household size for France, Sweden, the United Kingdom (England and Wales), and, particularly, Japan, show some reverses and irregularities in the course of their declines, though long-range trends are indisputably clear. India provides very rare and valuable historical data, since the trend displayed may be representative of other less developed countries. The Indian data show that household size has been increasing, instead of decreasing, since 1921. The same type of trend was also observed in Japan at an early stage in that country's development, as well as in many Latin American countries, and the Republic of Korea for which trend data over a short period are available.

37. Sweeping declines in average household size among the more developed countries have been well documented in the literature. In a world-wide review, Levy formulated three developmental types of societies according to their predominant family structure with or without modern medical technology. He hypothesized that a society undergoes transformation from one type to another, suggesting long-run declines in family and household size in the course of modernization. According to Levy's hypothesis, among the individual countries average household size gradually becomes smaller and the international variation narrows.<sup>47</sup>

<sup>47</sup> Levy, "Aspects of the analysis ..." (1965), pp. 48-60. The first type includes "societies devoid of modern medical technology", the second type refers to those "with highly developed modern medical technologies", and the third type is that of "transitional" societies.

TABLE X.4. PERCENTAGE DISTRIBUTION OF HOUSEHOLDS BY SIZE, FOR THE UNITED STATES OF AMERICA:  
1790, 1900, 1950 AND 1960

<i>Census year</i>	<i>All households</i>	<i>1 person</i>	<i>2 persons</i>	<i>3 persons</i>	<i>4 persons</i>	<i>5 persons</i>	<i>6 persons</i>	<i>7 persons</i>	<i>8 persons</i>	<i>9 persons</i>	<i>10 or more persons</i>
1790 .....	100	3.7	7.8	11.7	13.8	13.9	13.2	11.2	9.0	6.5	9.0
1900 .....	100	5.1	15.0	19.6	16.9	14.2	10.9	7.7	5.2	3.2	3.1
1950 .....	100	9.3	28.1	22.8	18.4	10.4	5.3	2.7	1.4	0.8	0.9
1960 .....	100	14.7	28.2	18.7	17.5	11.0	10.0				
(6 or more persons)											

SOURCES: For the years 1790, 1900 and 1950, percentage figures were taken from Winnick, *American Housing and its Use* . . . (1957), p. 79. The percentage distribution for the year 1960 was computed from data in United States, Bureau of the Census, *U.S. Census of Population: 1960, Persons by Family* . . . (1964).

38. Taeuber and Taeuber, Glick, Winnick and others agree that the decline in household size in the United States of America has been an outstanding demographic fact, that it has been widespread since 1790 and that the long-term decline in average size has been accompanied by sharp increases in the proportion of very small households—those composed of one and two persons—and by even more dramatic decreases in the proportion of very large households.<sup>48</sup> Since the early days of the nation, the relative numerical importance of small households has more than tripled, their combined share in the total number of households rising from 11.5 to 41.9 per cent by 1960 (see table X.4). Also, the increase has occurred at the same time as the declines in extended families and in multigenerational families.<sup>49</sup>

39. In the United Kingdom (England and Wales) average household size before 1801 was somewhere between 5.1 and 4.6. It appears not to have changed markedly between the pre-industrial era and that which succeeded it in the nineteenth century. Thus, it is interesting to observe that average household size changed little during the period of demographic transition associated with industrialization<sup>50</sup> and the fall in the average size came late, starting somewhere around 1901 (see table X.3).

40. As table X.3 indicates, the gross reproduction rate in England and Wales dropped from 2.3 to 1.7 between 1851 and 1901, whereas during the same period the average household size fluctuated around 4.4-4.6, but did not show any clear sign of declining. By 1911 a downward trend in household size had clearly set in, and it later became rapid and consistent. By 1966, the average size of household had shrunk to 3.01.

41. Thus, the persistent decline in average household size started about 20 to 30 years later than the inception of fertility decline in England and Wales. This suggests

that the considerable fertility decline which would otherwise have contributed to reducing household size had been offset by the decline in mortality which normally has the effect of increasing average household size. In fact, mortality decline had already started well before 1851<sup>51</sup> and the onset of the decline in the net reproduction rate took place only around 1881, having lagged 10 to 20 years behind the decline in the gross reproduction rate.<sup>52</sup>

42. The British experience outlined above further suggests that the nuclearization of families caused usually by rural-urban migration and associated with the general rise in the standard of living did not take place during the nineteenth century to such a degree that it combined with the force of fertility decline to offset the effect of mortality decline and produce a real decline in the average household size. Nuclearization, it appears, set in only after the beginning of the twentieth century, and it gathered momentum only after the Second World War.<sup>53</sup> Even during the post-war period when fertility was substantially increased (the gross reproduction rate being raised from 1.0 to 1.4 and the net reproduction rate from 1.0 to 1.3 between 1951 and 1961), household size still decreased appreciably, from 3.19 in 1951, to 3.04 in 1961, and to 3.01 in 1966.

43. The fundamental changes in the size distribution of households that caused the secular decline in the average household size are shown in table X.5, which summarizes the changes in the percentage distribution of private households by size group in England and Wales for the period 1911 to 1966. These tables show a persistent and very remarkable increase in the proportion of small size

<sup>51</sup> Petersen, *Population* (1961), p. 393. Also, data compiled by Glass show that the decline in the crude death rate in England and Wales took place around 1750, while the birth rate started to decline after 1870. See Glass, "Population and population movements in England . . ." (1965).

<sup>52</sup> Wrigley, *Population and History* (1969), p. 195.

<sup>53</sup> Laslett hypothesized that the decline was largely due to the disappearance in the twentieth century of domestic servants, who had constituted a large number in pre-twentieth century British society. See Laslett, "Size and structure of the household . . ." (1969); and his *Household and Family in Past Time* (1972). In the present chapter, the term "nuclearization" may be broadly interpreted not only to denote the process of undoubling or separating off of multigenerational families into nuclear families and one-person households, but also to include the process of disappearance of domestic servants from their employers' households.

<sup>48</sup> Taeuber and Taeuber, *The Changing Population* . . . (1958), pp. 170-171; Glick, *American Families* (1957), pp. 21-23; Winnick, *American Housing and its Use* . . . (1957), p. 79. Also see Morton, *Housing Taxation* (1955), pp. 70-73.

<sup>49</sup> Kirkpatrick, *The Family as Process* . . . (1963), pp. 137-138.

<sup>50</sup> Laslett, "Size and structure of the household . . ." (1969), pp. 210-211. Some data are available from as far back as 1564. However, the data available between 1564 and 1801 constituted a rather small sample, and average household sizes for these years may not be comparable to the figures available since 1801 based on the population censuses.

TABLE X.5. PERCENTAGE DISTRIBUTION OF PRIVATE HOUSEHOLDS BY SIZE CLASS  
IN THE UNITED KINGDOM (ENGLAND AND WALES), 1911-1966

Size class of household	Year					
	1911	1921	1931	1951	1961	1966
Total .....	100	100	100	100	100	100
Small (one to three persons) ..	40.8	44.5	52.7	63.6	65.4	67.2
One-person .....	(5.3)	(6.0)	(6.7)	(10.7)	(11.9)	(15.4)
Two to three persons .....	(35.5)	(38.5)	(46.0)	(52.9)	(53.5)	(51.8)
Medium (four to six persons) .	42.9	41.9	39.1	33.0	32.0	30.4
Large (seven persons) .....	16.3	13.6	8.2	3.4	2.6	2.5

SOURCES: For 1911: Nixon, "The size, constitution and housing standards ..." (1935), p. 144. For 1921: Laslett, "Size and structure of the household ..." (1969), p. 212. For 1931 and 1951: Nixon, "On the size, constitution and housing standards of households ..." (1952), p. 136. For 1961: United Kingdom, General Register Office, *Census, 1961, England and Wales; Household ...* (1966), p. 28. For 1966: United Kingdom, General Register Office, *Sample Census 1966, Great Britain ...* (1967), p. 46.

households (1-3 persons), from 40.8 per cent in 1911 to 67.2 per cent in 1966. Up to 1931, the increase was more prominent in the 2-3 person households, but thereafter it was more striking in one-person households, from 6.7 per cent to 15.4 per cent between 1931 and 1966. From 1931 to 1951, the number of these households more than doubled<sup>54</sup> and by 1966 had more than tripled.<sup>55</sup> Between 1961 and 1966, although the 2-3 person household group showed a decrease in its percentage share, the substantial increase in the one-person households enabled the share of the small-size household group as a whole to show a further increase.

44. As opposed to these trends, the medium size households (4-6 persons) show a gradual but substantial decline, the reduction being particularly large between 1931 and 1951. A large decline is evident in large size households of seven persons and over. In fact, this category is shown to have almost disappeared, falling from 16.3 per cent in 1911 to 2.5 per cent in 1966. These features are similar to those observed in the United States of America, as well as in Western and Eastern European countries and Japan, as seen below.

45. In many of the Eastern European countries, statistics on households and families have been developed only after the Second World War, thus not permitting the study of long-term trends. Moreover, numerous territorial changes in this part of Europe make it rather difficult to compare pre-war and post-war data.

46. In all Eastern European countries—with the exception of Poland and Yugoslavia—household size declined continuously throughout the period for which data are available. Although the decrease in the average size of households between the period 1930-1931 and the post-war census years can be ascribed partly to the changes in the definition of households,<sup>56</sup> there is no doubt that

in all the countries studied the decrease constitutes a long-term social and demographic process. The extent of these changes can be best seen in Czechoslovakia and Yugoslavia, where average household size declined during a forty-year period from 4.31 to 3.13 in the former country and from 5.10 to 3.99 in the latter (table X.6). It is interesting, however, to note that in Yugoslavia the decrease was not linear between 1921 and 1948 and that during the period 1921-1931 there was an increase in average household size.

TABLE X.6. TRENDS OF AVERAGE HOUSEHOLD SIZE  
IN CZECHOSLOVAKIA AND YUGOSLAVIA

Czechoslovakia		Yugoslavia	
Year	Average size	Year	Average size
1921 .....	4.31	1921 .....	5.10
1930 .....	3.93	1931 .....	5.14
1950 .....	3.38	1948 .....	4.37
1961 .....	3.13	1953 .....	4.29
		1961 .....	3.99

SOURCES: For Czechoslovakia, 1921 data computed from Sestavil Státní úřad statistický, *Statistický přehled ...* (1930); 1930 data from Státní úřad statistický, *Statistická ročenka ...* (1957); 1950 data supplied by Federální statistický úřad; 1961 data from Federální statistický úřad, *Statistická ročenka ...* (1969). For Yugoslavia, Rančić, "Utjecaj nekih demografskih i socio-ekonomskih faktora ..." (1966), p. 200.

47. Increases in household size, which are rather unusual in the recent history of Europe, occurred in Poland after the Second World War. The average size of households in Polish cities increased from 2.84 to 3.09 between 1950 and 1960. At the same time, the proportion of small households—those containing one to three persons—declined from 68.0 to 60.9 per cent, while that of households with four or more members increased from 32.0 to 39.1 per cent.<sup>57</sup> Further analysis shows that not only average household size, but also the number of adults per household rose—from 1.81 to 1.90 during this period. Viewed in a different way, this means that the headship rate per adult population, i.e., the number of households per adult population at each census

<sup>54</sup> Nixon, "On the size, constitution and housing standards of households ..." (1952), p. 136.

<sup>55</sup> *Ibid.* See also United Kingdom, General Register Office, *Sample Census 1966, Great Britain ...* (1967), p. 3.

<sup>56</sup> The new definitions of households adopted in the censuses taken after the Second World War have in practically every country led to a marked increase in the number of one-person households. This was dealt with explicitly by Litterer-Marwege, *Rozwój Ludności Polski a planowanie ...* (1967), pp. 237-239.

<sup>57</sup> Poland, Główny Urząd Statystyczny, *Rocznik statystyczny, 1964* (1964), p. 39.

year, dropped from 55.2 to 52.6 per cent.<sup>58</sup> While interpretation of these changes is complicated, three major factors appear to be involved: first, the considerable decrease in one-person households owing to socio-economic changes;<sup>59</sup> secondly, the cumulative effects of high fertility between 1950 and 1955 which resulted in a higher proportion of children in the population in 1960 as compared to 1950;<sup>60</sup> and thirdly, the effects of long-term declining mortality which caused an increase in the average number of adults, as well as of children, per household in Polish urban communities.<sup>61</sup>

48. As in the United States of America, and the United Kingdom, the general trend of decreasing household size in Eastern Europe has been accompanied by considerable changes in the distribution of households by size, namely an increase in the proportion of small households and a decrease in that of large households. In Czechoslovakia substantial increases are noted both in the one-person and two-person households—from 10.8 to 14.3 per cent and 23.4 to 26.8 per cent, respectively, between 1950 and 1961. On the other hand, the medium-size and the large-size households show downward trends.<sup>62</sup>

49. In Hungary, also, substantial increases are observed in the two-person and three-person families and decreases in the four-and-more-person families. Already in 1949, Hungary was noted for its small proportion of large families, as those of six persons and over constituted only 10.7 per cent, but this figure had further decreased to 5.8 in 1960 and to 5.3 in 1963.<sup>63</sup>

50. The experience of Japan with regard to changes in average household size is of special importance because of its implications for developing countries, since Japan is the only Asian country which has completed the stages of demographic revolution in response to socio-economic transformation from a rural-agricultural to an urban-industrial society, and since these demographic and socio-economic changes took place so recently and so dramatically within a short time.

51. As shown in table X.3, at the time of Japan's first national census in the modern sense in 1920, the average household size was 4.99 persons.<sup>64</sup> The 1930

census revealed, however, an increase to 5.08 persons and a further rise to 5.13 was recorded at the 1935 census. After 1935, however, there was a slow decline which persisted until 1955, when the average reached the level of the 1920s. After 1955, the downslope suddenly steepened, with a fall to 4.52 in 1960, 4.08 in 1965, and 3.72 in 1970.

52. The gross reproduction rate declined considerably from 2.56 to 2.13 between 1920 and 1935, the latter being the census year when the average household size reached its peak at 5.13 persons. In other words, average household size was increasing, while fertility declined considerably. This implies that although the effect of the fertility decline towards reducing average household size was substantial, other forces operating in an opposite direction were stronger. Thus, there appears to have been a time lag between the start of fertility decline and the reduction of the average household size.

53. In the case of pre-war Japan, the forces which cancelled out the effect of fertility decline were a perhaps more significant decline in mortality<sup>65</sup> and the tenacity of the extended family system in some sectors of the Japanese society.<sup>66</sup> According to Tachi, during the 1920s and 1930s, the nuclearization of families did not take place in Japan, as had occurred earlier in the West, despite the fact that industrialization and urbanization were fairly well advanced and that a considerable fertility decline had occurred. He further argued that the effects of mortality decline can easily outweigh the effects of fertility decline on household size since the effects of annual fertility change upon the age structure of population are limited to the age group under one year and, therefore, they are only cumulatively effective in influencing the whole population structure, whereas those of annual mortality change have direct effects upon all ages even though they are normally greatest in ages under five.<sup>67</sup>

54. Changes in the distribution of households by size in Japan also follow the general patterns observed in Europe and Northern America. That is to say, they show a considerable increase in one-person households, a sizable increase in the medium-sized households (two to five persons), and a marked decrease in the large-sized households (six persons and over). The changes in percentage distribution of private households are shown in table X.7.

<sup>58</sup> Computed from census data.

<sup>59</sup> One-person households declined from 25.7 to 21.1 per cent of all households. Poland, Główny Urząd Statystyczny, *Rocznik statystyczny*, 1964 (1964), p. 39.

<sup>60</sup> United Nations, *Demographic Yearbook*, 1970 ... (1971), table 6.

<sup>61</sup> Between 1952-1953 and 1960-1961, life expectancy at birth for males rose from 58.6 to 64.8. United Nations, *Demographic Yearbook*, 1966 ... (1967), table 21.

<sup>62</sup> 1950 data supplied by Federální statistický úřad; 1961 data from Jureček, "Velikost a struktura domácností ..." (1963), p. 195.

<sup>63</sup> Tamásy, "A Magyar családok nagysága és összetétele" (1964), p. 411; Szabady, "A Magyar családok demográfiai sajátosságai" (1966), p. 1062.

<sup>64</sup> Official data on average size of households are not available before 1920, but Hayami made estimates for some provinces in Tokugawa Japan from the seventeenth to nineteenth centuries. Although there were considerable variations from region to region, most households were reported to have been surprisingly small, mostly between four and five persons in the eighteenth and nineteenth centuries. See Hayami, "The population at the beginning of the Tokugawa period ..." (1966-1967); Hayami and Uchida, "Analysis of trends in the mean size of households ..." (1972).

<sup>65</sup> The crude death rate decreased substantially from 25.4 per 1,000 in 1920, to 20.3 in 1925, to 18.2 in 1930, and to 16.8 in 1935. Japan, Ministry of Health and Welfare, *Showa 42-nen jinko dotai tokei*, vol. 1 (1970), p. 86. At the same time life expectancy at birth rose from 42.1 for males and 43.2 for females in the period 1921-1925 to 46.9 and 49.6 years, respectively, in the period 1935-1936. Japan, Ministry of Health and Welfare, *Dai 9-kai seimeihyo* (1955), pp. 78-81 and pp. 86-89.

<sup>66</sup> This does not mean, however, that Japanese families even in 1920 were predominately of the extended family form consisting of three or more generations. In fact, they were more dominantly of the nuclear family type. See Toda, *Kazoku kosei* (1953); Koyama, "Kazoku kosei no henka" (1962); and Morioka, "Kazoku no keitai" (1966), pp. 6-9. According to a sample of 11,216 households from the 1920 national population census, the average household size was 4.9 persons and the average family size was 4.5 persons. See Toda, *Kazoku kosei* (1953).

<sup>67</sup> Tachi, "Jinko tenkan katei kara mita ..." (1967), especially pp. 78-81.

TABLE X.7. CHANGES IN PERCENTAGE DISTRIBUTION OF PRIVATE HOUSEHOLDS  
BY MAJOR SIZE-CLASS IN JAPAN, 1920-1965

Size-class of household	Year					
	1920	1930	1950	1955	1960	1965
Total .....	100	100	100	100	100	100
One person .....	5.7	5.5	5.4	3.5	5.2	7.9
Two to five persons .....	57.6	56.1	56.2	58.6	64.4	71.4
Six persons and over .....	36.7	38.4	38.4	38.0	30.4	20.7

SOURCE: Based on the 100-per cent count of respective censuses. See Kono, "Changes in households and family structure ..." (1971).

55. From table X.7 it is clear that the distribution of households by size-class was remarkably stable from 1920 to 1955, except for some slight decreases in the percentage of one-person households and small increases in that for the medium-size and large-size households which were partly due to the consequences of the post-war marriage and baby booms, and partly due to changes in the definition of "household", which particularly affected the number of households.<sup>68</sup> Since 1955 the distribution has changed suddenly and substantially. It is observed that the percentages of the small- and medium-size households have increased, and conversely the percentage of large households with six persons or more has declined, the latter trend being particularly significant.

56. For the past sixty years India has shown a relatively stable average household size, although it has been increasing more recently. For instance, household size was found to be larger in many states of India in 1941 than

in 1931. Though definite trends had not been observed in the past, they were obvious for the decade 1951-1961, when household size increased in the rural and urban areas of many states, as well as in the national average (see table X.3). Thus, it would appear that much of the discussion in the sociological literature on the prevalence of the joint family in the past and its gradual break-up in recent years does not find substantial support from the census data.<sup>69</sup>

57. Orenstein also examined similar data from the successive decennial censuses by individual states from 1911 to 1951 and found that, contrary to expectation, there was no sign of a decrease in household size in the period 1911-1951. Data for earlier years are sporadic, but a review of them offers little to contradict this finding. The longest time-series given in Orenstein's study, for the State of Punjab, shows the following trend:<sup>70</sup>

<sup>68</sup> Dandekar and Unde, "Inter-state and intra-state differentials ..." (1967), pp. 325-326.

<sup>70</sup> Orenstein, "The recent history of the extended family ..." (1961), p. 345.

Year	1855	1868	1881	1891	1911	1921	1931	1941	1951
Average household size	4.5	4.3	4.6	4.7	4.5	4.6	4.8	5.2	4.9

Sampling data from many other states, the author concluded that household size in India up to 1951 had not declined.<sup>71</sup>

58. Orenstein recognized that the relative constancy in average household size did not necessarily imply that the long-maintained joint family system was still intact, since it was possible that the effects of its decline were obscured by the substantial declines both in crude death rates and infant mortality rates which had been realized in India<sup>72</sup> and which tended to expand family size. He found, however, that the proportions of married and widowed men per household, instead of declining as would be expected with a decline in extended families, had shown some increase from 1911 to 1951 in most of the states. The weighted average ratio, which could be

taken to roughly represent India as a whole, was 1.31 in 1911, 1.26 in 1921, 1.38 in 1931 and 1.33 in 1951. These data support the conclusion that the joint family had not decreased in significance.<sup>73</sup> While there are some growing tendencies in India's recent history, such as a growth of individualism, an increase of rural-urban migration and a rise in the standard of living, which would tend to encourage a disintegration of joint or extended families, such factors were apparently offset by the effects of mortality decline, unaccompanied by fertility decline. Dandekar and Unde maintain that the increase in average household size in India recently has been due mainly to the decline in mortality.<sup>74</sup> Because mortality improvements have followed an uneven pattern, being concen-

<sup>71</sup> *Ibid.*, p. 346.

<sup>72</sup> See, for example, estimates in Davis, *The Population of India and Pakistan* (1951), pp. 34-35.

<sup>74</sup> Dandekar and Unde, "Inter-state and intra-state differentials ..." (1967), pp. 316-317.

trated heavily among the young, the size of the child population has increased relatively more than that of the adult population.

### 3. DEMOGRAPHIC TRANSITION AND DECLINE IN AVERAGE HOUSEHOLD SIZE

59. The foregoing review of historical trends in selected countries reveals some interesting features of the interactions between demographic factors and average household and family size. When data became available in the West, the process of modernization, the decline in fertility and the reduction in average size of household and family were already in progress. During the period for which observation is possible, substantial reductions in household and family size parallel with fertility declines are seen to have occurred, although certain exceptions and fluctuations are noted, particularly in France, Sweden, the United Kingdom and Yugoslavia (see table X.3). On the other hand, in the case of Japan, the demographic transition and historical changes in household and family size began quite differently, and the initiation of a trend towards modernization in Japanese families, as expressed in shrinking family size, lagged almost half a century behind the inception of fertility decline.

60. In the developing societies of Asia and Latin America, where doubled-up households are still of some numerical importance, rapid mortality decline without substantial fertility decline has currently been causing increases in average household and family size. Burch noted that in Panama, for example, average household size rose from 3.9 in 1940 to 4.5 in 1950 and then to 4.7 in 1960. In Nicaragua it increased from 5.9 to 6.1 between 1950 and 1963, and in Mexico from 5.0 to 5.4 between 1950 and 1960.<sup>75</sup> Moreover, in El Salvador, family size grew from 5.1 to 5.4 between 1950 and 1961, and in Costa Rica, from 5.6 in 1950 to 5.7 in 1963. In Asia, average household size increased in the Republic of Korea from 5.66 in 1955 to 5.71 in 1960; in India, from 5.0 to 5.2 between 1951 and 1961; in Iran, from 4.8 to 5.1 between 1956 and 1966; in Ceylon, from 5.0 to 5.4 between 1953 and 1963; and in the Philippines, from 5.5 to 5.8 between 1948 and 1960.<sup>76</sup> It may be expected that these increases will halt eventually, and family size will start to decrease after the demographic transition has proceeded further, and fertility decline overtakes mortality decline.<sup>77</sup> Application to the developing countries of Tachi's interpretation of the interrelationship between demographic factors and average household size in the framework of the demographic transition theory<sup>78</sup> is completely in agreement with Levy's general hypothesis,<sup>79</sup> as outlined above. Developing Levy's sociological framework,<sup>80</sup>

Burch also generalizes that a rise in average household size could occur as an early response to modernization simply because of the rise in the average number of surviving children. As fertility levels begin to fall in developing countries, in response to lower mortality levels and changed living conditions, the demographic transition is likely to have its parallel in family and household structure.<sup>81</sup>

### D. Patterns and differentials in headship rates

#### 1. NOTION OF THE HEADSHIP RATE

61. The headship rate denotes a ratio of the number of heads of households by sex, age, marital status etc., to the corresponding categories of population.<sup>82</sup> The concept of the headship rate is very important since it is a pivot around which the modern method of projecting households and families turns.<sup>83</sup> It also serves as a good indicator for measuring the degree of housing privacy enjoyed by each segment of the population<sup>84</sup> and has been used as an index for measuring the extent of joint family.<sup>85</sup>

62. As pointed out earlier, the family is viewed as a product of purely demographic factors such as fertility, mortality, nuptiality and divorce, but the household is considered a product of those demographic factors plus conditioning or intervening socio-economic factors. Accordingly, the gap between the household headship rate and family headship rate in a certain sex-age group signifies the degree of doubling-up of families within households.<sup>86</sup>

63. In a recent United Nations study, forty-three different sets of census household headship rates by sex and age pertaining to thirty-three countries have been examined.<sup>87</sup> To facilitate analysis, the data were first divided according to the dichotomy of more developed and less developed regions and secondly by three *per capita* income groups (see tables X.8 and X.9).

<sup>81</sup> Burch, "The size and structure ..." (1967), pp. 360-361.

<sup>82</sup> Of course, the headship rate can also be computed for families as well as households. However, the household headship rate is far more meaningful and far more frequently employed in analyses and projections than the family headship rate. Therefore, unless otherwise mentioned, headship rates given in the present chapter are household headship rates.

<sup>83</sup> United Nations, *Manual VII: Methods of Projecting Households and Families* (1973), p. 31.

<sup>84</sup> Beresford and Rivlin, "Privacy, poverty, and old age" (1966), p. 247. According to these authors, privacy can be measured statistically by the proportion of households containing only one person or one nuclear family. Changes in the proportion of persons over a specified age reported in the census as "head" or "wife of head" of the household also reflect changes in the degree of privacy.

<sup>85</sup> Dandekar and Unde, "Inter-state and intra-state differentials ..." (1967), p. 331.

<sup>86</sup> The United Nations statistical definition assumes that the family is always included within a household and not vice versa. Also, it should be noted that households may consist of only one member, whereas there can be no one-member families. See United Nations, *Principles and Recommendations for the 1970 Population Censuses* (1969), pp. 20-21.

<sup>87</sup> United Nations, *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

<sup>75</sup> Burch, "The size and structure ..." (1967), p. 360.

<sup>76</sup> *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

<sup>77</sup> *Projections of the Number of Households and Families*, to be issued as a United Nations publication.

<sup>78</sup> See Tachi, "Jinko tenkan katei kara mita ..." (1967), p. 80.

<sup>79</sup> Levy, "Aspects of the analysis ..." (1965), especially p. 49.

<sup>80</sup> *Ibid.*, p. 56. Levy correctly notes that the major initial effect of declining mortality would be to increase the number of surviving children.

TABLE X.8. UNWEIGHTED AVERAGE AGE-SPECIFIC HOUSEHOLD HEADSHIP RATES FOR MALES AND FEMALES IN THE THIRTY-ONE COUNTRIES WITH AVAILABLE HEADSHIP DATA CLASSIFIED ACCORDING TO THE LEVEL OF DEVELOPMENT, AROUND 1960<sup>a</sup>

(Percentage of heads among population of given age group)

Degree of development	Age (years)					
	15-24	25-34	35-44	45-54	55-64	65 and over

Less developed <sup>c</sup> .....	2.4	8.5	15.9	24.6	32.7	37.0

SOURCE: United Nations, *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

<sup>a</sup> Data for six countries were available only for years around 1950.

<sup>b</sup> Includes data for twenty countries.

<sup>c</sup> Includes data for eleven countries. Of the thirteen developing countries included in the study, Guadeloupe and Martinique are here excluded partly because of their rather abnormal age patterns and partly because of their small populations.

## 2. SEX-AGE-SPECIFIC HEADSHIP RATES IN COUNTRIES AT DIFFERENT LEVELS OF DEVELOPMENT

64. Table X.8 shows unweighted average age-specific headship rates for the more developed and less developed country groups. The age patterns of headship rates closely resemble those of economic activity rates. As in the latter, the male headship rates are higher than the female rates at all age groups.<sup>88</sup> This simply reflects the fact that in all societies man in his prime of life assumes the role of chief bread-winner in the household as well as the main responsibilities for family affairs, apart from domestic chores, child-bearing and child-rearing.

65. As in the case of labour force participation rates, the specific headship rate for males is low in the young ages, but it increases with increasing age and reaches a peak around 90 per cent sometime after age forty-five. For example, in the United States of America (1960) it occurred in the age group 45-49 years (90.8 per cent). In Sweden (1965), it fell in the age group 60-64 years (92.8 per cent); in Japan (1965) in the age group 50-54 years (93.8 per cent); in Hungary (1960) in the age group 50-54 years (89.3 per cent); in Panama (1960) in the age group 55-64 years (86.4 per cent). Indeed, of thirty-one countries included in the present analysis, nearly all showed peak headship rates for males either in the ten-year age group 45-54 or 55-64 years. These are ages when men generally reach the apex of social power and prestige, bolstered by the highest earnings of their lifetime.<sup>89</sup> Noting that decreasing employment opportunities and declining health with advancing age increasingly limit the possibilities for maintenance of separate households by elderly men, Winnick pointed out that whereas more

than nine out of ten men in their sixties in the United States are listed as household heads, after age seventy-five the proportion was only about seven out of ten.<sup>90</sup>

66. Differences in age-specific headship rates between the more developed and less developed countries are less significant for males than for females. In all except the youngest age group, male headship rates are uniformly higher in the more developed than in the less developed countries. For the 15-24 age group, the higher average headship rate found in the less developed countries is largely influenced by the high levels reported in India (West Bengal, 1951) and to a lesser extent in Brazil. India, of course, is noted for very early marriages of boys still in their teens.<sup>91</sup> Indeed, of the thirty-eight censuses studied, a very high correlation (+0.80) was found between the headship rate for this young age group and the percentage of the population who were married. For the other five age groups, coefficients of correlation were much less significant.<sup>92</sup>

67. The patterns for females show much wider differences than do those for males between the more developed

<sup>88</sup> Winnick, *American Housing and Its Use* ... (1957).

<sup>91</sup> For example, see Agarwala, *Age at Marriage in India* (1962), chaps. 4, 5, 9; and Collver, "The family cycle in India and the United States" (1963).

<sup>92</sup> On the other hand, between the headship rate and the percentage of agricultural workers as indicating the degree of economic under-development, the correlation is negative and relatively insignificant for this youngest age group of 15-24, while the other age groups show negative values, varying from considerably significant (-0.57 for age group 35-44 and -0.54 for 45-54) to insignificant (-0.20 for 65 years and over). It might be hypothesized that higher male headship rates for age group 15-24 in the less developed countries are attributable to higher economic activity rates in the less developed countries than in the more developed ones (see chapter IX). However, the coefficient of correlation between the headship rate and the economic activity rate for the age group 15-24 was only +0.17. Moreover, application of multiple regression analysis to assess relative importance of the level of development, economic activity rate and percentage ever-married showed that the factor of marital status could explain about 81 per cent of the variation of headship rates for the age group 15-24.

<sup>88</sup> This was pointed out by Winnick. See his *American Housing and Its Use* ... (1957), p. 94.

<sup>89</sup> Woytinsky, *Earnings and Social Security* ... (1943), pp. 228-249; Sweden, Statistiska Centralbyrån, *Folk-och bostadsräkningen den 1 November 1965; IX* ... (1969), pp. 46-47, 54-55; United States, Bureau of the Census, *Income in 1969 of Families and Persons* ... (1970), p. 85.

<sup>d</sup> Under \$ U.S. 400.

and less developed countries. There is a similar tendency in both country groups for headship rates to be very low in the youngest age group, and then to increase with the advancement of age. But, beyond this point there are few analogous features between them. Except for the youngest age group, the less developed countries show higher rates than the more developed countries in all age groups—precisely opposite to the pattern found among males. The difference between the two groups is slight at the youngest ages, but it widens at middle age, and at ages 35-44 the rate for the less developed is almost twice as high as that for the more developed countries. At ages 55-64 years, the rate for the less developed countries exceeds that for more developed by 9.4 per cent. Curiously enough, for the age group 65 and over, the difference narrows to only 2.5 per cent.

68. Of various correlation coefficients that were calculated, only that between the headship rate and the percentage of women not currently married was found to be very significant, particularly for the middle age group of 45-54 (+0.74) and to a lesser degree for the surrounding age groups of 34-44 years (+0.43) and 55-64 years (+0.47). On the contrary, in the youngest age group, marital status was found to be scarcely relevant to the level of headship rate.

69. Demographic studies of the determinants of sex-age specific headship rates are virtually non-existent. From the United Nations preliminary analyses, it appears that female headship rates are not significantly related to marital status except in the middle age groups where, if women are widowed, divorced or single, they are more likely to have their own households. In other age groups, the marital status factor is insignificant. On the whole, the probabilities of women becoming heads of house-

holds appear to be much more unpredictable than those of men.

### 3. SEX-AGE-SPECIFIC HEADSHIP RATES BY THREE MAJOR *per capita* INCOME GROUPS

70. Table X.9 shows unweighted average sex-age-specific household headship rates for three groups of countries classified by income level.<sup>93</sup> As far as the male rates are concerned, a typical uni-modal curve is observed in each of the three groups of countries. It is noted that intergroup variations are small in the age groups 45-54 and 55-64 years, where rates in the vicinity of 90 per cent are observed, whereas variations are large in the age groups 65 and over, and particularly at ages 25-34. At ages from 25 to 64, rates are highest in the highest-income countries and lowest in the low-income countries. In the age group 15-24, on the other hand, rates for the low-income countries are higher than those for the countries with high or medium income. And at ages 65 and over, the low-income countries show higher rates than the medium-income countries. It must be emphasized, however, that the medium-income and low-income countries for which data are available are probably not very

<sup>93</sup> Thirty-one countries for which data are available have been classified as follows:

(a) High *per capita* income: Australia, Belgium, Canada, Denmark, Federal Republic of Germany, Finland, France, Luxembourg, the Netherlands, Norway, Sweden, Switzerland and the United States of America.

(b) Medium *per capita* income: Argentina, Austria, Czechoslovakia, Greenland, Hungary, Italy, Japan, Puerto Rico, Singapore and Trinidad and Tobago.

(c) Low *per capita* income: Brazil, Costa Rica, El Salvador, Guatemala, Haiti, India, Nicaragua and Panama.

TABLE X.10. TRENDS OF SEX-AGE-SPECIFIC HOUSEHOLD HEADSHIP RATES  
FOR THE UNITED STATES OF AMERICA AND JAPAN  
(Percentage of household heads among population of each sex-age group)

65 and over .....	27.4	32.7	31.8	36.3	9.4	10.4	11.8

SOURCE: *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

representative of these groups as a whole.<sup>94</sup> The countries here included in the medium-income group are geographically and culturally heterogeneous, unlike the high-income group. If the thirty-one countries are classified by region, the average rates for all age groups, except for the group 15-24 years, are arrayed from high to low in the following order: Europe and North America (eighteen countries), Latin America (ten countries) and Asia (three countries).

71. For females the pattern is generally opposite to that for males. Except for the youngest age group, 15-24 years, and the oldest age group, 65 years and over, low-income countries show higher headship rates than high-income countries. In each income group, peak female headship rates occur at ages 65 years and over. A particularly sharp increase in rates between the age group 55-64 and the oldest age group studied is found in the high-income group. Regionally, the high female headship rates in Latin America above age 25 are noteworthy.

#### 4. CHANGE IN SEX-AGE-SPECIFIC HEADSHIP RATES

72. A number of studies in Europe, Japan and the United States of America have revealed that generally headship rates have increased over time in all sex-age groups except in the middle-age groups of females.<sup>95</sup> Increases are particularly notable at ages under 35 years for both sexes.

<sup>94</sup> These include only three countries in Asia and none in Africa.

<sup>95</sup> Winnick, *American Housing and Its Use* ... (1957), chap. 8; United States, Bureau of the Census, *Illustrative Projections of the Number of Households and Families* ... (1958); Cullingworth, *Housing Needs and Planning Policy* (1960), chaps. 1-4; Needleman, *The Economics of Housing* (1965), pp. 20-26; Japan, Institute of Population Problems, *Zenkoku todofuken betsu setaisu* ... (1966); Beresford and Rivlin, "Privacy, poverty and old age" (1966); Parke and Grymes, "New household projections for the United States ..." (1967); Kono, "Changes in households and family

73. Because of their striking contrasts, trends in sex-age headship rates for Japan and the United States of America are shown in table X.10. In both countries a remarkable increase in headship rates has occurred among males in the youngest age groups, 15-24 and 25-34 years. Significant increases have also occurred in headship rates for both males and females in the age group 65 years and over. These are the ages where the widest difference in headship rates is found between the two countries, those for the United States being substantially higher than those for Japan.

74. On the other hand, in the ages from 35 to 64 years, headship rates have been relatively stable for both sexes in Japan, and for females in the United States of America. Rates for males of these ages in the latter country have shown a moderately rising trend. Relatively lower headship rates for these age groups among United States males than among Japanese males may be due to the fact that the United States has been using the housing-unit approach, while Japan has been employing the housekeeping-unit approach: the housing-unit approach usually excludes lodgers and roomers as heads of households, while the housekeeping-unit approach includes these persons in the category of household heads.<sup>96</sup>

structure in Japan" (1971). Valuable studies have also been issued by the Governments of Denmark, Finland, the Netherlands, Norway and Sweden in mimeographed form. The above publications do not constitute an exhaustive list of studies concerning the world-wide phenomena of general increases in sex-age headship rates, but they do document the major trends in this area.

<sup>96</sup> The housekeeping-unit approach regards the household as a person or group of persons living in the same housing unit and having common provisions for essential living needs, particularly food, whereas the housing-unit approach is concerned only with one aspect—living in the same housing unit; hence, an application of the housing-unit concept obviously does not provide information for the direct analysis of two or more separate housekeeping groups sharing the same dwelling unit.

## 5. PATTERNS OF SEX-AGE-MARITAL STATUS-SPECIFIC HEADSHIP RATES

75. In addition to sex and age, marital status is an important characteristic for the analysis of household and family headship. Tables X.11 and X.12 show sex-age-marital status-specific headship rates for Sweden and Japan, two countries which represent different stages with regard to "nuclearization" of families or "undoubling" of households.

76. While there are certain similarities in the pattern of rates for males in the two countries, there are also

important differences. In both Japan and Sweden, the highest headship rates are shown for married men, followed by widowed, divorced and single men. The headship rates in Sweden exceed those in Japan in each age-marital status group, the difference being particularly great for single males and for men 65 years of age and over in all marital status groups. Higher headship rates at advanced ages are typical of highly developed countries with a long history of industrialization.

77. The pattern among females is quite different in the two countries, though widowed women in each have the highest headship rates, followed by divorced, single

TABLE X.13 UNWEIGHTED AVERAGES OF HOUSEHOLD SIZE AND OTHER DEMOGRAPHIC INDICATORS

<sup>a</sup> Number of private households per 100 population aged 20-64 years.

and married women. The extremely low rates for married women in both countries reflect the universal tendency to consider the husband as head of household in cases where a married couple are living together.

78. It is interesting to note that for Sweden the female headship rates for the single, widowed and divorced are at least as high as the male rates for most age groups, and for the divorced group in particular, the female rates are substantially higher than the male rates. For Japan, on the other hand, for the widowed and divorced groups, the female rates are substantially lower than the male rates in the advanced ages. High rates for single, widowed and divorced women also prevail in other countries of Western Europe and Northern America where such women frequently live in independent households, particularly in urban areas. Such living arrangements are less common in Asia and other areas.<sup>97</sup> The relatively low headship rates for single women in Japan, as well as for widowed and divorced women above age 55, show a considerable contrast with the patterns prevailing in Sweden. Even lower headship rates are found among women in these age and marital status categories in a country like India.<sup>98</sup>

#### E. Factors affecting the number and size of families and households

79. One of the most important purposes in studying demographic aspects of households and families is to gain knowledge of factors affecting their dimensions and trends. Such knowledge is useful in dealing with many questions of policy and formulation of action programmes in the economic and social fields. In particular, it provides

<sup>97</sup> Caplow, *The Sociology of Work* (1964), especially pp. 230-247; *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

<sup>98</sup> Japan, Bureau of Statistics, *Showa 40-nen kokusei chosa* . . . (1970), pp. 178-183; Dandekar and Unde, "Inter-state and intra-state differentials . . ." (1967), pp. 332-333. The Indian data were available only for the state of West Bengal in the 1951 census.

a basis for projections of numbers of households and families which are of vital importance for the planning of economic and social development, especially in the field of housing.

#### 1. MAJOR REGIONAL DIFFERENCES

80. Regional averages of household size and other demographic indicators are presented in table X.13. This table confirms the well-known dichotomization between the more developed and less developed countries of the world. A wide gulf is evident between the countries of Europe and European overseas settlement (except Latin America), on the one hand, and those of Latin America, Asia and Africa, on the other, in respect to demographic aspects of household and family structure as well as fertility and mortality indicators. The former group is seen to have (a) a distinctly smaller average household size, (b) a far greater percentage of households with two to four persons, (c) a substantially larger percentage of households with two to six persons, (d) a substantially higher total headship rate, (e) a far smaller gross reproduction rate, and (f) an unmistakably longer length of life.

81. Less variation is observed among the three developing regions, although apparently Africa is considerably different from the other less developed regions in that it has a higher percentage of small-sized households (two to four persons), and a lower average household size.<sup>99</sup> These findings are no doubt associated with the lower life expectancy compared to that in Asia and Latin America. At the same time, Africa's relatively high headship rate and large proportion of small households with two to four persons suggests that perhaps the nuclear family structure is more prevalent in Africa than in Latin America and Asia, and certainly more prevalent than previously

<sup>99</sup> This is also shown in the United Nations estimates of average household size, in 1965, for the three regions (see table X.1).

believed.<sup>100</sup> The paucity of available data, however, precludes definite conclusions. The smaller average household size in Latin America than in Asia, in spite of approximately the same regional levels in fertility and mortality, may be explained by Latin America's noticeably higher headship rate for the population aged 20-64.

## 2. SEX-AGE STRUCTURE

82. The number and size of households and families can be considered as determined, on the one hand, by the size and sex-age-marital status composition of the population and, on the other, by the schedule of sex-age-marital status-specific headship rates. In some statistical assessments of the effect of these two factors, marital status may have to be omitted from consideration because of the unavailability of relevant data. In the foregoing discussion on the patterns of headship rates by sex and age (see section D), it was seen that the chances of becoming a household head are high at ages 25-64 years for the male population as well as for the single, widowed and divorced female population. It was further noted that this age group constitutes a much lower proportion of total population in the less developed than in the more developed countries. On this account, with identical schedules of sex-age-specific headship rates, the less developed countries would have relatively smaller numbers of heads of households and families and, therefore, smaller numbers of households and families than the developed countries.

83. The size and composition of the population is determined, in turn, by the conditions of fertility, mortality and nuptiality and by their changes in the course of time. The social, economic and other factors affecting the changes in fertility and mortality have already been treated in the previous chapters of this volume. The sex-age specific headship rates can be considered as representing the net result of economic, social and cultural influences such as the level of living, degree of industrialization and urbanization, demands for various consumer durables, which are all relevant to the propensities to become the head of household or family among persons in each demographic category.

84. A simple way of assessing the relative effect of (a) sex and age structure of the populations; and (b) differing schedules of headship rates on the number and average size of households is illustrated in table X.14. This table shows the results of a two-way standardization procedure whereby two different schedules of sex-age specific headship rates based on data for twenty developed, and eleven developing countries, respectively, are applied to the sex-age structure, first, of the more developed regions and, second, of the less developed regions. The results show that the differences in sex-age structure of the population of the two regions has a much greater influence on average household size than do differing headship rates. As the table shows, when the data are

standardized for sex-age composition, differences in average household size between developing and developed regions are greatly reduced, whereas standardization by sex-age-specific headship rates reduces differences only to a small extent. While there are differences in sex-composition between the populations of developed and developing regions, as shown in chapter VIII, the age structure is the major factor accounting for differences in average household size.

85. The standardization approach has also been used to examine the relative influence of demographic factors and headship rates on changes in household numbers and size between census dates in some countries. For example, Bamas, using such techniques, found that changes in headship rates accounted for most of the increase in the number of households in France between 1954 and 1962. Changes in sex-age structure and marital status, on the contrary, had relatively little effect and tended in the opposite direction. The general increases in headship rates were attributed to increased nuclearization of households, including the establishment of increasing numbers of one-member households as a result of internal migration etc.<sup>101</sup>

TABLE X.14. AVERAGE HOUSEHOLD SIZE, ACTUAL AND STANDARDIZED, FOR SEX-AGE COMPOSITION AND SEX-AGE-SPECIFIC HEADSHIP RATES, ON THE BASIS OF THE 1965 ESTIMATED DATA

(Persons per household)

Sex-age composition of population for :	Sex-age-specific headship rates for	
	More developed	Less developed
More developed .....	3.54 (actual)	3.74
Less developed .....	4.85	5.22 (actual)

SOURCE: Population data from *World Population Prospects as Assessed in 1968*, to be issued as a United Nations publication. Data on headship rates from thirty-one population censuses (for twenty more developed and eleven less developed countries). See *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

86. In Japan, where the average size of private households declined from 4.97 in 1955 to 4.05 in 1965, the change was attributed to three factors as follows: (a) a decline of 70 per cent to changes in the sex-age composition of the population which had resulted from fertility decline; (b) a decline of 40 per cent to changes in sex-age-marital status-specific headship rates; and (c) an increase of 10 per cent to changes in marital status composition within each sex-age group.<sup>102</sup>

87. Of a 23 per cent increase in the number of private households in the Federal Republic of Germany, from 1957 to 1969, 17 per cent was attributable to changes in demographic factors, that is, in the sex-age-marital status composition of population, and 6 per cent to social and economic factors. During this period, one-person house-

<sup>100</sup> Citing several sources, Goode reported average household sizes so small that extended kin households could not be common. The shortage of housing facilities in urban areas has been cited as a factor. See Goode, *World Revolution and Family Patterns* (1963), pp. 188-189.

<sup>101</sup> Bamas, "L'évolution du nombre des ménages ..." (1966), particularly pp. 9-12.

TABLE X.15. TOTAL MALE HEADSHIP RATES IN MODEL STABLE POPULATIONS WITH VARIOUS LEVELS OF FERTILITY AND MORTALITY AND TWO SCHEDULES OF MALE AGE-SPECIFIC HEADSHIP RATES  
(Male heads of households as percentage of total male population)

Gross reproduction rate	Expectation of life of thirty years		Expectation of life of fifty years		Expectation of life of seventy years	
	A	B	A	B	A	B
4.0 .....	29	25	26	22	24	21
3.0 .....	35	31	32	28	30	26
2.0 .....	45	39	42	36	40	35
1.0 .....	62	54	59	52	58	51

SOURCE: Stable populations were based on the "West" model of Coale and Demeny, *Regional Model Life Tables* ... (1966). Headship rates were computed on the basis of thirty-one available sex-age-specific headship schedules and were later adjusted to the estimated total numbers of heads of households for 1965 for the more developed and less developed countries respectively. Such age-specific male headship rates are shown below. It may be noted that these schedules differ from the unweighted averages for the thirty-one countries shown in table X.8.

	Age group (years)						
	15-24	25-34	35-44	45-54	55-64	65 and over	
More developed .....	11.1	70.5	90.0	94.0	93.3	81.3	
Less developed .....	12.6	56.6	77.2	82.6	82.9	73.6	

Column A. Average age-specific headship rates for more developed countries.

Column B. Average age-specific headship rates for less developed countries.

holds increased by 72 per cent, while the multimember households increased only by 12 per cent. In the case of the latter, demographic factors account for the entire increase since, in their absence, the total number of multimember households would have decreased, owing to the negative influence of non-demographic factors.<sup>103</sup>

88. For the United States, Winnick demonstrated that changes in sex-age structure between 1890 and 1950 could have caused a decline of 27 per cent in average household size, while social and economic influences on headship rates could account for only about 5 per cent.<sup>104</sup>

89. Other similar studies have nearly all shown that the structural changes in population and not changes in headship rates have been predominantly responsible for large increases in numbers of households and the corresponding declines in their average size that have occurred since the beginning of this century.<sup>105</sup> Thus, Needleman concluded that the two main elements accounting for the declining average size of household during the last fifty years or so are the rise in the proportion of adults in the population and the increase in the number of people who are, or have been, married.<sup>106</sup>

### 3. FERTILITY AND MORTALITY

90. The eventual effects of varying fertility, mortality, and age-specific headship rates upon the total male

headship rate have been analysed by means of a stable population model. The total male headship rate denotes the total number of male household heads per 100 total male population. The results, summarized in table X.15, show the importance of fertility as the primary determinant of the total male headship rate, and therefore the size of the household, in the long run.<sup>107</sup>

91. Under given conditions of mortality and age-specific headship rates, when the gross reproduction rate drops from 4.0 to 1.0, the total male headship rate in this model more than doubles. Lowering mortality rates (i.e., increasing expectation of life) with other factors constant has an opposite, but much less pronounced effect. On the other hand, with fertility and mortality constant, the shifting from the schedule of age-specific headship rates for the less developed countries to that for the more developed countries causes moderate increases in the male headship rate, particularly in the case where fertility is very low (gross reproduction rate of 1.0). While the latter effect is much smaller than that of a large decrease in fertility, it appears to be generally stronger than that of mortality change.

92. There has been little systematic investigation of relations of demographic variables of fertility, mortality and nuptiality to the structure and size of households. Coale calculated variations in average household size from a stationary population, with high fertility, high mortality and early age at marriage, according to various family systems. He found that in the family system involving maximum extension of households, average house-

<sup>103</sup> Federal Republic of Germany, Statistisches Bundesamt, "Statistisches Umschau: Bevölkerung—Entwicklung ..." (1970), pp. 346-348.

<sup>104</sup> Winnick, *American Housing and Its Use* ... (1957), p. 82.

<sup>105</sup> For example, see Japan, Bureau of Statistics, *Nihon no jinko, Showa 35-nen* ... (1963), pp. 222-223; Needleman, *The Economics of Housing* (1965), p. 25; Szabady, "Demographic characteristics of the Hungarian families" (1967); Wander, "Demographic aspects of housing conditions in the Federal Republic of Germany" (1967), p. 448; Tamásy, "Age structure of Hungarian families" (1968), pp. 409-415.

<sup>106</sup> Needleman, *The Economics of Housing* (1965), p. 25.

<sup>107</sup> Changes in fertility are not immediately reflected in the numbers of families and households. Actually, for about twenty years a fall in the number of births has very little effect on the number of families and households; it merely diminishes the number of children and adolescents in them. However, when the third decade after the number of births has undergone a material decline is reached, the size of the population in marriageable ages will begin to fall and will bring about a corresponding fall in the number of new families and households.

hold size was 75 per cent larger than for the nuclear family system under the same demographic conditions.<sup>108</sup>

93. Burch expanded the Coale model by using the model stable populations of differing mortality and fertility levels and applying to them a set of headship rate assumptions representing four family types: (a) nuclear family, (b) extended family with foster mother, (c) extended family without foster mother, and (d) stem family.<sup>109</sup> The distinctions between these four types are governed by the pattern of timing in the setting up of a new household by a woman after her marriage. A nuclear family results when a new household is established immediately upon the woman's marriage. An extended family form with foster mother is one where the woman continues to live with her own mother, and after her own mother's death, with a foster mother until the death of the foster mother. An extended family without foster mother refers to a situation where the woman establishes her own household after her own mother's death. Finally, a stem family is one established immediately upon the woman's marriage, her own mother being already dead. If her mother is still alive, she or one of her sisters remains in the mother's household until the death of the mother, and then succeeds to the mother's headship. The other sisters set up their own new households immediately after marriage.

94. According to Burch's models, in the nuclear family system, fertility, owing to its powerful influence on age structure, is a more important factor affecting household size than mortality and nuptiality. In the extended family type, the relative effects of fertility and mortality tend to be roughly equal, fertility having a slight edge. In the stem family system, with its rather complicated hypothetical conditions, mortality tends to have a slightly greater influence than fertility, particularly at high levels of fertility. The most important general conclusion to emerge from Burch's analysis is the strong independent effect of fertility on average household size. Burch also considered different variants of age at marriage in his models and found that later marriages tended to make for somewhat larger households on average, assuming that they did not result in lower fertility.<sup>110</sup>

95. While the use of stable population models for isolating the effects of fertility and mortality has obvious advantages, Burch's application has certain shortcomings, as the author himself admitted. First, the assumptions on age at marriage and family types are too simple and unrealistic. Moreover, the use of female, instead of male stable population as the basis for estimating household formation increases the chances of error in estimating average household size, since universally a great majority of household heads are males. This type of analysis may be better accomplished by computer simulation models of household formation and dissolution over the family

life cycle.<sup>111</sup> However, in order to construct a comprehensive simulation model, more must be known about the complex and dynamic mechanisms of formation, growth and dissolution of households, for example the probabilities of forming new households on the part of newly married couples at each age, the probabilities of maintaining one-person or non-family households among the young and aged populations etc. At the same time, it is also desirable to make use of multidecremental nuptiality and marriage tables, fertility tables by duration of marriage and parity, and family life tables.<sup>112</sup>

96. Empirical studies dealing with factors affecting the size and structure of households and families have also demonstrated that declining fertility has played the most important role in the secular decline in average household size among the developed countries since the turn of the twentieth century. For example, Glick's analysis for the United States shows that the decline has been largely the result of the long-term downward trend of the birth rate, even though the decline in the death rate and other factors have played a part. For example, the increase in the number of aging parents surviving beyond the time when their children left home, largely due to improvements in medical science and public health, and the increase in marriages of young persons after the Second World War, must have accounted for much of the long-term increase in the proportion of small households and, in turn, contributed to the declining trend of average household and family size.<sup>113</sup>

97. In a more recent study, Parke made a distinction between factors affecting family structure and those affecting household structure. In the case of the family, he maintained that since there had not been much further acceleration in nuclearization, recent changes in the average family size in the United States from the late 1940s to the mid-1960s had practically been governed by changes in fertility. On the other hand, in the case of households, it was argued that in addition to the important role of fertility, the increasing prominence of one-person households and the decreasing tendency for households to include non-relatives or employees living-in had helped to reduce the average size of households.<sup>114</sup>

<sup>111</sup> A pioneering micro-simulation of matching of marriages and formation of families and households was made by Orcutt, Greenberger, Korbel and Rivlin. See Orcutt *et al.*, *Microanalysis of Socio-economic Systems* ... (1961), pp. 232-256.

<sup>112</sup> Though the construction of family life tables has long been considered, few attempts have been made in this direction because of the complex nature of the processes of family formation and dissolution and the paucity of relevant data. Perhaps the closest approach is Brown's "Analysis of a hypothetical stationary population ..." (1951).

<sup>113</sup> Glick, *American Families* (1957), pp. 22-23. In his more internationally-oriented analysis, Bogue mentioned three factors as major determinants of average household size in a population. They are: (a) the level of fertility; (b) the extent to which elderly relatives, especially parents, are able to maintain themselves financially and can afford to live separately from their children in their own households; and (c) the extent to which unmarried persons leave home and establish "bachelor households" either alone or with one or more friends of the same sex. Bogue, *Principles of Demography* (1969), pp. 370-371.

<sup>114</sup> Parke, "Changes in household and family structure ..." (1971), pp. 2255-2256. See also Parke and Glick, "Prospective changes in marriage ..." (1967), pp. 255-256.

<sup>108</sup> Coale, "Appendix: estimates of average size of household" (1965), p. 68.

<sup>109</sup> Burch, "Some demographic determinants of average household size ..." (1970), pp. 62-64.

<sup>110</sup> Burch, "Some demographic determinants of average household size ..." (1970), pp. 64-68.

98. Schubnell and his colleagues have identified some of the major factors contributing to the shrinkage of the average household size in the Federal Republic of Germany, where the proportion of one-person and other small-sized households has been rising, while the proportion of large-sized households has been falling. These factors include declining fertility; the trend toward earlier marriage, resulting in the formation of more new households; increase in the proportion of older persons, many of whom live alone; the erosion with industrialization of the agrarian family where several generations may have lived together on a farm; and a general improvement in housing conditions which enables more older people to be accommodated in their own households.<sup>115</sup>

99. Most studies of households and families in Eastern European countries have stressed that the decline in the average household size has been caused primarily by demographic factors, chiefly by the declining fertility rate, and only secondarily by social and economic factors.<sup>116</sup>

100. The impact of the decline in fertility on average family size in Hungary has been cited by Tamásy. Between 1949 and 1963 average family size declined from 3.57 to 3.24,<sup>117</sup> and the percentage of families without children rose from 27 per cent in 1949 to 31 per cent in 1960. The number of families with only one child also increased, while the number with more than three children showed a significant decline. Other factors in the shrinking size of Hungarian households were also noted, such as the shifting of marriages to earlier ages, as well as increases in the number of marriages concluded at more advanced ages, in duration of marriage beyond the reproductive ages and in the proportion of children leaving parental families due to earlier marriages and increasing employment opportunities.<sup>118</sup>

101. In Yugoslavia, Rančić's studies confirmed the decisive importance of fertility. Of five demographic, social and economic variables tested, the birth rate and the percentage of illiterates in each republic were found to be most closely correlated with the average size of households, the correlation coefficients being 0.78 and 0.79, respectively.<sup>119</sup> Similar conclusions regarding the decisive influence of fertility on the size of households were drawn also by Jureček in Czechoslovakia. Analysing data from 109 Czechoslovak districts, he found a high correlation between the average number of persons per household and the average number of children under 15 years in the household.<sup>120</sup>

<sup>115</sup> Schubnell, Borries and Rupp, "The concept and use of household and family statistics . . ." (1971).

<sup>116</sup> Litterer-Marwege, who emphasizes social and economic factors, is an exception in this respect. See his *Rozwoj ludności Polski a planowanie* . . . (1967).

<sup>117</sup> Tamásy, "A Magyar családok nagysága . . ." (1964), p. 410.

<sup>118</sup> Tamásy, "Magyarország népességének család-összetétele" (1961).

<sup>119</sup> Rančić, "Utica nekij demografskih i socio-ekonomskih faktora . . ." (1966).

<sup>120</sup> Jureček, "Velikost a struktura demácností . . ." (1963), pp. 200-201. A high positive correlation (0.87) between the gross reproduction rate and average household size was found in a United Nations study which examined data for eighty-seven countries. Of all factors

102. The importance of marriage and marital status as factors influencing the size and structure of households and families is only too obvious and has been widely documented by demographers and sociologists.<sup>121</sup> This is especially so in the sense that marriage constitutes the first step in the formation of the biological family, and most newly wed couples establish their own households immediately after their wedding.<sup>122</sup>

103. Changes in the proportion of other marital status groups besides the "married" also have an important bearing on the size and structure of families and households. As has been seen in a foregoing section, a change in the proportion of single persons substantially affects the total headship rate and, therefore, the average household size in a complex way. Generally, the single population has lower headship rates than other marital status groups, excepting married females, whose rates are negligible. However, in the developed countries headship rates for single persons have become increasingly higher, sometimes surpassing 50 per cent, particularly among females, and those single persons having their own households form the bulk of one-person households.<sup>123</sup> Migration of single persons to urban areas often works in two ways toward a decline in average household size, first by reducing the size of the parents' households, and secondly by increasing the proportion of small-sized households in the area of in-migration.

104. In the case of women, divorces and deaths of husbands strongly affect headship status. As has already been seen, headship rates for married women are naturally close to the zero point, but in developed countries headship rates for widowed and divorced females are as high as those for widowed and divorced males, who have only slightly lower rates than the married. Therefore, increases in the proportion of widowed and divorced population generally produce a rise in headship rates among women and contribute to a shrinkage of average household size. It has been noted, however, that recently, particularly

tested, the gross reproduction rate showed by far the most significant correlation with household size. See *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

<sup>121</sup> For example, Glick, *American Families* (1957), pp. 53-60; Taeuber and Taeuber, *The Changing Population* . . . (1958), p. 166; Macura, "Contribution à l'étude des familles incomplètes . . ." (1959); Schubnell, "Introductory comments" (1963), p. 155; Tachi, *Jinko bunseki no hoho* (1963), p. 167; Needleman, *The Economics of Housing* (1965), p. 19; United Nations, *Methods of Estimating Housing Needs* (1967), p. 56; Dandekar and Unde, "Interstate and intra-state differentials . . ." (1967), pp. 317-321; Hajnal, "European marriage patterns in perspective" (1965), p. 132; Angenot, "Age structure and number of dwellings in the Netherlands" (1967), p. 398.

<sup>122</sup> For example, Glick, "The family cycle" (1947); and his *American Families* (1957), pp. 53-70; Kono, "Wagakuni setaisu no shorai . . ." (1961); Wander, "Demographic aspects of housing conditions . . ." (1967), pp. 447-448; Volkov, "The analysis of family structure in projecting the number . . ." (1967), pp. 106-107. Not all newly married couples immediately form their own families and households; a minority of them remain in the home of their parents or in-laws and share in the same household budget. This is sometimes referred to as a "doubling-up" of family and household.

<sup>123</sup> In all four Scandinavian countries including Finland, this tendency has been clearly observed.

in the developed countries, increases in length of life among men as well as women have reduced the proportions of widowed women in every age group, so that if other things were equal, this decrease in the proportion of widowed women would tend to reduce female headship rates, thus contributing to an increase in average size of household.

105. Studies carried out in a few countries have not revealed particularly significant effects of changes in marital status upon household size. This is not because the factor of marital status *per se* is unimportant, but because during the periods studied the sex-age composition of the population by marital status did not change substantially enough to override or offset the opposing forces of fertility decline and increases in headship rates (nuclearization). For example, as mentioned above, in Japan between 1955 and 1965, the marital status factor is estimated to have effected a slight increase in family size, while actually average household size decreased rather markedly, owing to fertility decline.

106. The most recent household projections for the United States under different marriage and headship assumptions can also serve to assess the effect of various factors on the number of households.<sup>124</sup> Growth of the adult population accounts for two thirds to three fourths of the increase in the number of households that occurs in the projection which combines household headship and marital status assumptions leading to the largest number of households. While population growth overshadows trends in marital status and household headship rates in its effect on the growth in household numbers, significant differences in future increases in the number of households are nevertheless produced by varying the household headship rate and marriage assumptions. The results show, however, that variations in household headship rates have a far more important effect on the total number of households than do variations in marriage assumptions. The latter factor has a significant effect on the projected increase in the number of young husband-wife households, but since these form a small fraction of all households, their effect on total household growth is not great.<sup>125</sup>

107. Several Eastern European authors, among them Tamásy, Litterer-Marwege and Rosset, have drawn attention to the decrease in the age at first marriage since the Second World War and its consequences for trends in household size.<sup>126</sup> The rapidly rising divorce rates in

Eastern Europe have also contributed to the decline in household size, although Czechoslovakian data, for example, show that the majority of divorced men remarry.<sup>127</sup> There remain, however, rather large numbers of divorced women who have children and who do not remarry, forming so-called incomplete families. For Czechoslovakia, statistical estimates show that the proportion of this type of household has been growing, from 7.9 per cent in 1961 to 8.1 per cent in 1964, and, further, to 8.3 per cent in 1967.<sup>128</sup> In Hungary recently there has also been a similar percentage increase in this type of household.<sup>129</sup>

108. In this connexion, attention should be drawn to an important phenomenon which helps to explain the very low average household size in Eastern Germany: 2.69 in 1950 and 2.50 in 1964. According to Strohbach and Triller, the great proportion of one-person households in Eastern Germany was and still is due to a disproportionately large number of war widows.<sup>130</sup> This factor probably also influenced the structure of households in Polish cities in the post-war period.

109. Relatively late marriage in the economically developed countries is accompanied by a high incidence of bachelorhood and spinsterhood, whereas in the less developed countries, where earlier marriage prevails, single persons at adult ages are relatively less numerous. The second striking feature of contrast is a much larger percentage of widowed persons, particularly among females in the older ages in the developing countries, owing to higher mortality. In the post-war period, opposing trends in age at marriage have been observed: in the developed countries where marriage had previously occurred relatively late, it tended to occur earlier, while in the developing countries, where it typically took place at an early age, the trend was towards later marriage.<sup>131</sup> The process of modernization and industrialization in the developing countries can be expected eventually to bring about further substantial changes in marital status by age which will produce important effects on average family and household size.<sup>132</sup> The question of marriage in the context of the family life cycle is discussed in more detail in section F.

## 5. ECONOMIC AND SOCIAL FACTORS

110. As already noted, in addition to the changes in population composition which have tended to reduce average household size in the more developed countries, social and economic factors also worked to the same end by increasing age-specific household headship rates. These increases, which occurred among all segments of the

<sup>124</sup> United States, Bureau of the Census, *Projections of the Number of Households and Families* ... (1968).

<sup>125</sup> Parke and Grymes, "New household projections for the United States" (1967).

<sup>126</sup> Tamásy, "A Magyar családok nagysága ..." (1964); Litterer-Marwege, *Rozwoj ludności Polski a planowanie* ... (1967); Rosset, "Wiek nowożeńców w Polsce" (1963). The decrease in age at first marriage was more pronounced in Eastern Europe than in Western Europe and is perhaps related to a lowering of legal age of marriage from 21 to 18 years in some of these countries. During recent years, however, average age at marriage among newly married couples has been stabilized, and efforts are even being made to postpone the marriages of young men.

<sup>127</sup> Kučera and Srb, "Rozvodovost v Československu v letech 1950-1959" (1962).

<sup>131</sup> Bogue, *Principles of Demography* (1969), pp. 362-363.

<sup>132</sup> See, for example, Parke and Glick, "Prospective changes in marriage and the family" (1967).

population except females in the middle age groups, are considered to be fundamentally related to trends in urbanization, the rise in *per capita* income, improved employment and housing conditions, and the like. The fact that demographic factors have generally assumed a more prominent role than socio-economic factors in affecting household size does not mean that the latter have lacked importance.

111. In the United States, socio-economic factors have been responsible for reducing the proportions of double-up households, as well as those which include lodgers, domestic servants and other non-related persons.<sup>133</sup> Winnick noted the decreases in doubling-up for younger married couples, even while one or both of the partners were still in college. Good job opportunities, veterans' military allowances and a high geographical mobility were among the factors providing strong incentives for the establishment of independent households. Winnick also observed that the tendency of young women not yet married to maintain their own apartments was increasingly becoming an American folkway, and was made possible by favourable employment conditions and greater social acceptance.<sup>134</sup> In the United Kingdom, the rise in real incomes of young people is said to have strongly influenced the trend towards earlier marriage, which in turn affected the average size of household.<sup>135</sup>

112. Various writers have identified a number of key social and economic factors which influence household formation. These are included in the following paragraphs.

#### (a) *The desire for privacy*

113. The desire for privacy<sup>136</sup> and independence and even physical insulation from others appears to have deep roots in the value systems of Western societies, being closely linked with the rise of individualism, political democracy, and instrumental rationalism ("Zweck-

rationalität").<sup>137</sup> On the other hand, such desires are relatively foreign to non-western cultures, which have rather tended to emphasize such concepts as continuity of the family, group solidarity and cohesion, respect and care for the aged, and group responsibility for the welfare and survival of kin.

#### (b) *Income and economic resources*

114. The ability of the individual or family to afford the type of household arrangement conforming to its desires is also of much importance. While this depends mainly on the family's or individual's income level, it is also related to the standard of living in the country or region and the housing market, which governs the relative levels of rentals, prices of houses and mortgages. Poor families must first spend their incomes on the main necessities of life: food and, to a lesser degree, clothing. They may choose to economize on housing by doubling up with other relatives. In such circumstances, privacy may be considered a luxury. As income increases, however, the percentage spent on food declines,<sup>138</sup> and once families rise out of the poorest income class, their income is spent on a wider variety of items of better quality, and privacy often comes to be considered one of the important items that money can buy.<sup>139</sup>

115. The relationship between income and household formation has been studied mainly in regard to relationships between total income or total consumption expenditure and housing expenditure. For the United States, Morton and Winnick show that the percentage of total expenditure for housing maintained a relatively stable figure even when income expanded.<sup>140</sup> This means that as income increased, a larger amount of money was spent on housing.<sup>141</sup> Certainly, a secular increase in income brings improvement in housing,<sup>142</sup> even though there is a considerable lag. A secular rise in national income, other things held constant, can be expected to be accompanied by an increase in demand for housing.<sup>143</sup> The expansion in effective demand for housing stimulates not only the undoubling of households to increase privacy but also the acquiring of more rooms or space per household or of higher-quality structures and facilities. In the higher income brackets, it may mean an increase in the proportion of second houses for use during weekends or vacations.

<sup>133</sup> Glick, *American Families* (1957), p. 23. As far back as 1938, the United States National Resources Committee noted some of the ways in which the number of families is influenced by economic conditions. See ———, *The Problems of a Changing Population* (1938), pp. 25-27.

<sup>134</sup> Winnick, *American Housing and its Use ...* (1957), pp. 96, 100. In 1940, whereas only one young unmarried woman in eight between the ages of 25-29 maintained her own household, by 1950 this figure had increased to one in five and by 1960 it had jumped to one in two. See United States, Bureau of the Census, *Census of Population: 1960*, vol. 1, part 1 (1964), pp. 436-437, 457-458. Young unmarried men also increased their headship rates, but not as dramatically as did women. *Ibid.*, p. 69. The role of socio-economic factors in increasing the proportion of one-member households is also discussed by Parke. See his "Changes in household and family structure ..." (1971), pp. 2255-2256. On similar trends in Japan and the Federal Republic of Germany, see Ueda, "Wagakuni setai kozo ..." (1969); Schubnell, Borries and Rupp, "The concept and use of household and family statistics ..." (1971).

<sup>135</sup> Needleman, *The Economics of Housing* (1965), p. 25.

<sup>136</sup> Reference to the desire for privacy was made by Winnick and later by Beresford and Rivlin. See Winnick, *American Housing and its Use ...* (1957), p. 7; Beresford and Rivlin, "Privacy, poverty and old age" (1966), pp. 247-258. The desire for privacy may also be identified with "taste", the concept often used by economists to refer to extra-economic factors, or it may be considered to fall in the realm of "social habits". On the latter, see United Kingdom, Royal Commission on Population, *Papers*, vol. 3 ... (1950), p. 22.

<sup>137</sup> See, for example, Mill, *On Liberty* (1859); 1956 ed.); Tönnies, *Einführung in die Soziologie* (1931); Parsons, *The Structure of Social Action ...* (1949); Davis, *Human Society* (1949); Riesman, *The Lonely Crowd ...* (1953); Freedman, "The sociology of human fertility ..." (1961/62); and Taeuber, "Demographic modernization ..." (1966).

<sup>138</sup> Engel, "Die Productions- und Consumptions ..." (1895); see also Lorimer and Roback, "Economics of the family ..." (1940), pp. 133-134.

<sup>139</sup> Beresford and Rivlin, "Privacy, poverty and old age" (1966), p. 247.

<sup>140</sup> Morton, *Housing Taxation* (1955), pp. 42-43; Winnick, "Housing; has there been a downward shift ..." (1955), pp. 87-88.

<sup>141</sup> See Muth, "The demand for non-farm housing" (1960), pp. 29-31.

<sup>142</sup> Gordon, "Population growth, housing and capital coefficients" (1956); Reid, *Housing and Income* (1962), p. 393.

<sup>143</sup> Atkinson, "Factors in the housing market" (1960); Reid, *Housing and Income* (1962), p. 390.

116. The lack of adequate time-series data precludes analyses of the relationship between income and household formation for many countries. Beresford and Rivlin noted that although incomes rose substantially between 1885 and 1940, Massachusetts census data do not indicate any significant shift towards undoubling of households between these two dates. Nevertheless, cross-sectional data for recent years in the United States suggest a high correlation between individual or family income and separate household maintenance. Within the young married group, for example, where the husband was under 25 years of age, the couples were considerably more likely to maintain a separate household if their joint income was high than if it was low. Young unmarried men were also more likely to maintain their own households in 1960 if their income was high than if it was low, and the same relationship persisted at older ages among the unmarried.<sup>144</sup> Glick found, moreover, that at a given age, a man is more likely to be married if his income is high than if it is low.<sup>145</sup>

117. Studies of patterns of living arrangements and income levels among unmarried elderly men and women based on 1952 and 1960 data showed in general that the higher the income the more likely were the individuals to maintain separate households. Moreover, for the women at least, the findings of the studies were not inconsistent with the hypothesis that rising income during the decade of the 1950s had led to more separate living on the part of the elderly.<sup>146</sup>

118. Swedish census data show a strong positive relationship between *per capita* income levels and household headship rates specific for sex-age and marital status groups. Correlation coefficients between headship rate and *per capita* income for each of twenty-six sex-age-marital status groups on the basis of the 1965 Swedish census data are generally very high, mostly more than 0.70, and in nine groups even higher than 0.90.<sup>147</sup> Higher income is clearly associated with higher headship rates and vice versa.<sup>148</sup>

119. A high negative correlation between *per capita* income and average household size was found in a United Nations study which examined data for eighty-seven countries. In fact, of all factors tested, income came next to gross reproduction rate in significance.<sup>149</sup>

### (c) Housing

120. General housing conditions in the community, the availability of vacant apartments or houses at reasonable prices, and government policies concerning the provision of housing all have a bearing on the numbers and

dimensions of households.<sup>150</sup> The availability of suitable housing is normally a limiting factor which slows down the spontaneous process of nuclearization and undoubling of households even if individuals have sufficient financial resources to spend for independent housing.

121. The limiting effects of housing formation have been observed in almost every European country, Japan, and the United States, immediately following war, especially the Second World War. In the United Kingdom, sex-age-marital status-specific headship rates were comparatively low in 1921 and, to a lesser extent, in 1951, and they rose appreciably between 1951 and 1961. These small variations can be explained, according to Needleman, almost entirely by the relative availability of housing accommodation. In both 1921 and 1951 there was a marked housing shortage which forced groups of persons who would otherwise have formed separate households to live together. Since 1951, the increase in house-building has enabled many of the concealed households of 1951 to set up on their own.<sup>151</sup> The same view was expressed by Paige, namely, that the increase in headship rates of about 5 per cent between 1951 and 1961 in the United Kingdom was mainly due to the reduction in the housing shortage over the period.<sup>152</sup>

122. In the Federal Republic of Germany, since 1950, the housing supply has expanded about three times as quickly as the demand and the extremely aggravated housing situation immediately after the Second World War has been greatly relieved. More than half of the dwellings existing in the Federal Republic of Germany in 1970 had been built since 1950 and during this span of time the quality of the dwellings improved. During the period between 1950 and 1970 the average household size further decreased from 2.99 to 2.63 and, aside from demographic factors, this reduction can be explained substantially by the increasing availability of dwelling units which either permit younger generations to marry earlier or to form one-person households and enable older generations to live by themselves.<sup>153</sup>

123. In the case of Japan, the situation is similar to the Federal Republic of Germany, though public and private household building to overcome the post-war housing shortage did not proceed as rapidly as in Germany. However, the decline in average household size, which has accelerated since 1960, undoubtedly reflects the rapidly expanding activities in housing construction which started around 1955. According to Takami's

<sup>144</sup> Beresford and Rivlin, "Privacy, poverty and old age" (1966), pp. 254-255.

<sup>149</sup> *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

<sup>150</sup> The influence of the housing factor or housing policies on household formation has been stressed by many authors. See Cullingworth, *Housing Needs and Planning Policy* (1960), pp. 65-71; Steigenga "Family structure, age-composition and housing needs" (1963); Needleman, *The Economics of Housing* (1965), p. 25; Musil, *Housing Needs and Policy* (1966), pp. 105-126; Ueda, "Wagakuni setai kozo ..." (1969), pp. 64-65. See also Andrie, Pojer and Ullmann, *Byty a bydlení v Československu* (1967); and Musil and Pazderová, *Sociologie asanačních oblastí českých měst* (1966).

<sup>151</sup> Needleman, *The Economics of Housing* (1965), pp. 24-25.

<sup>152</sup> Paige, "Housing" (1965), p. 368.

<sup>153</sup> Wander, "Demographic aspects of housing conditions ..." (1967), pp. 447-450; Schubnell, Herberger and Borries, "Households and families ..." (1971), pp. 6-8. In fact, the 1961 population census revealed that the Federal Republic of Germany had one of the highest series of sex-age headship rates attained in the world.

estimates, during the period 1971-1975 the absolute shortage in housing will be virtually solved and after this period a greater number of new houses and apartments will be constructed not primarily to provide increasing numbers of households, but for renewing and replacing old buildings and improving the quality of housing.<sup>154</sup>

124. Glick noted for the United States that in addition to economic considerations, the available supply of apartments and houses was an important factor affecting household formation. During the period of housing shortage immediately following the end of the Second World War, the proportion of young couples without their own living quarters was two and one-half times as large as it was in 1954, by which time the housing situation had greatly eased. In 1940, after years of depression when housing construction was at a generally low ebb, close to twice as large a proportion of young couples shared the living quarters of others as in 1954.<sup>155</sup>

125. A large part of the world's population is housed in unfit, unhealthy and overcrowded dwellings; it has been estimated that in Africa, Asia and Latin America, half of the population is either homeless or living in entirely unacceptable dwellings.<sup>156</sup> One problem lies on the production side in the developing countries. Low incomes and low savings rates and the urgent need to deploy as much capital as possible in new productive enterprises combine to magnify the difficulty of investing adequate amounts in the essentially consumer-oriented activity of housing construction. During the 1960s, notwithstanding the fact that in most developing countries urban population was growing more rapidly than total production, there was no great tendency to devote a higher proportion of available resources to the construction of dwellings.<sup>157</sup> The fact that headship rates for married males in the prime of life, say between ages thirty-five and sixty-five, have never actually reached the level of 100 per cent in any country, but at best 98-99 per cent, and are frequently lower than 90 per cent, is probably at least partly due to the effects of the housing shortage as a limiting factor on the demographic demands for household formation.<sup>158</sup>

#### (d) Internal migration

126. Internal migration has a very important impact on household size, particularly in rapidly urbanizing countries such as Japan and some Latin American countries. The significance of this factor lies in the fact that massive internal migration can cause nuclear fission or

undoubling of families even in a country where the nuclearization process is otherwise rather limited owing to deep-rooted extended family tradition.

127. Migration is nearly everywhere highly selective, and migrants consist predominantly of young adults (see chapter VI above). A great number of young migrants to urban places live in boarding houses or one-room apartments, thus forming either one-person households or else becoming part of group quarters or institutional households. The formation of many new small-sized households in urban areas, concomitant with internal migration, clearly contributes to lower average household size both in cities of in-migration and in countries or villages of out-migration.<sup>159</sup> In Japan, it was found that about 27 per cent of the decline in average household size between 1955 and 1965 was due to the formation of new one-person households, as a result of internal migration.<sup>160</sup>

128. In the course of the family cycle, better economic and social opportunities in urban areas may induce the husband or couple to migrate, thus bringing about changes in average family size and composition and possibly even in the eventual number of children born to the couple. At the other end of the family life cycle, it is frequently common, particularly in the less developed countries, for elderly couples to return to their villages of origin to spend the latter years of their lives, after residing during their reproductive years and bringing up their children in the town or city.

129. Changes other than purely demographic ones are likely to occur as a result of internal migration, in that the migrants' attitudes towards privacy, secularity, rationality etc. also undergo alteration as a result of the influences of an urban environment, and such changes undoubtedly tend to enhance household formation. However, as yet few studies have been undertaken which throw light on such socio-psychological and motivational aspects of household formation.

#### (e) Industrialization and related factors

130. Industrialization is a complex economic and social process encompassing technological developments that has profound and far-reaching effects on economic organization and social structure. Practically every author who has dealt with the question of the relationship between household and family structure and socio-economic factors has pointed out, or implied, that industrialization has an important bearing on household and family structure, directly or indirectly.<sup>161</sup>

<sup>159</sup> Litterer-Marwege, *Rozwoj ludności Polski a planowanie ...* (1967), p. 243; Wander, "Demographic aspects of housing conditions ..." (1967), p. 449; Cabello, "Housing, population growth, and economic development" (1966), p. 117.

<sup>160</sup> Kono, "Changes in households and family structure ..." (1971), p. 2228. See also Yamaguchi, "Setai kibo no fukukan ..." (1969), pp. 38-42; Takami, "Jutaku mondai no shorai" (1965), pp. 76-80.

<sup>161</sup> See, for example, Glick, *American Families* (1957); Taeuber and Taeuber, *The Changing Population ...* (1957); Levy, "Aspects of the analysis ..." (1967), pp. 40-63; Tachi, "Jinko tenkan katei kara mita ..." (1967), pp. 78-81; Burch, "The size and structure ..." (1967); Litterer-Marwege, *Rozwoj ludności Polski a planowanie ...* (1967), p. 243. According to the United Nations multiple regression study, the beta coefficient for the factor of industrialization was

(Continued on next page)

<sup>154</sup> Takami, "Jutaku mondai no shorai" (1965), pp. 85-86.

<sup>155</sup> Glick, *American Families* (1957), p. 61.

<sup>156</sup> United Nations, *The United Nations Development Decade ...* (1962), p. 59; ———, *Methods for Establishing Targets ...* (1968), p. 5. While it is generally considered that housing shortages are concentrated in urban areas, in Latin America the housing problem is much more acute in rural areas than in cities. See Cabello, "Housing, population growth, and economic development" (1966), pp. 112-114.

<sup>157</sup> United Nations, *World Economic Survey, 1969 ...* (1971), p. 51.

<sup>158</sup> United Nations, *Manual VII: Methods of Projecting Households and Families* (1973), pp. 35, 38-39.

However, since industrialization is so inseparably intertwined with other socio-economic factors such as urbanization, rise in *per capita* income, and the like, it is impossible to disentangle it from other factors and to measure the effects of industrialization *per se* upon the changes in the size and structure of household and family.

131. As discussed earlier, the emergence of the small nuclear family is generally viewed in sociological theory as a consequence of the urban-industrial revolution. The dominant sociological hypothesis relating technology and social organization postulates a functional interdependence between industrialization and urbanization, and the small nuclear family as the unit of social organization.<sup>162</sup> For example, Ogburn and Nimkoff postulated that with increasing industrialization the consanguine (extended) family tended to disappear and to be superseded by the conjugal (nuclear) family. Thus, they argue that the small nuclear family found in the United States took its present form as a result of national industrialization and urbanization. Within a system in a state of change then, one part is the cause of the new form taken by another part.<sup>163</sup>

132. In Europe, the best example of this line of thinking is presented by Max Weber, who views changes in the family as a function of its changing economic position that, in turn, is a function of the changes in the total society stemming from the industrial revolution.<sup>164</sup>

133. As was noted in section B, this hypothesis has recently been challenged and criticized by some sociologists and anthropologists who argued that, in the first place, in the Western societies, notably in England and Wales (United Kingdom), average household sizes had been surprisingly small and relatively stable before the Industrial Revolution, implying the widespread existence of small nuclear families even then, although the influence of industrialization was absent. Secondly, in the rural-agricultural societies of Africa and Asia, the extended family system and polygamy are rarely characteristic of the majority of the population. Where they exist, they are largely confined to the upper class of population, who constitute only a small proportion of the total population.<sup>165</sup> According to Goode, the relationship between

industrialization and nuclearization is independent and interacting. There exists only the "fit" of the nuclear family to industrialization, not necessarily implying a cause-effect relationship.<sup>166</sup>

134. Nevertheless, smaller families are unmistakably more prevalent in the urban-industrial and high-income countries than in the rural-agricultural and lower-income ones. As already pointed out, this is due in part to the fact that the urban-industrial countries are characterized by low fertility, whereas the rural-agricultural countries have unequivocally high fertility. Moreover, in the urban-industrial countries there is generally a greater tendency for the grown-up children to leave their parental households early and for the older persons to retain their own households than is the case for the rural-agricultural countries.

135. Various economic changes associated with the process of industrialization may exert an influence on household size. While the participation of women in economic activities may have an influence on household size, the nature of this relationship is not entirely clear. On the one hand, high activity rates for women may tend to reduce average household size through their effect in lowering fertility.<sup>167</sup> On the other hand, it has been argued that high female activity rates can lead to a slowdown in the process of household fission and to a renewal of the functions of the doubled-up family. In Czechoslovakia, households with employed women are larger in size than those where wives are not employed. This is due mainly to the fact that the households with employed women often include grandparents or other relatives who help to run the households.<sup>168</sup>

136. In a study for England by Eversley and Jackson, income, social and economic status and educational attainment were identified as the main determinants of household size in the sense that these factors not only affect the household size directly, but also indirectly through changing fertility and consequent alterations in age structure.<sup>169</sup>

## F. The life cycle of the family

### 1. FAMILY LIFE CYCLE AS A DEMOGRAPHIC FRAMEWORK

137. The family undergoes a sequence of characteristic stages in size and structure and between formation and dissolution which lend themselves to demographic analysis. These stages include marriage, establishment of a household, bearing and rearing of children, marriage of

(Footnote 161 continued)

significantly and negatively related to average household size, but its numerical weight was not particularly large, for example as compared with the factor of fertility. However, since the measure of industrialization used in this analysis, *viz.* the percentage of the male labour force engaged in non-agricultural industries, is too simplified to adequately represent the complex process of industrialization, which is so closely interlocked with other socio-economic factors, no great significance can be attached to the findings. See, *Demographic Aspects of Households and Families*, to be issued as a United Nations publication.

<sup>162</sup> Greenfield, "Industrialization and the family ..." (1961), p. 312.

<sup>163</sup> Ogburn and Nimkoff, *Sociology* (1950), p. 469; ———, *Technology and the Changing Family* (1955).

<sup>164</sup> Weber, *General Economic History* (1950), p. 111. Also see Greenfield, "Industrialization and the family ..." (1961), p. 315.

<sup>165</sup> It is not possible to view non-Western family systems as basically like the Western systems of some undefined earlier historical phase just before industrialization. The evolutionary theory may be in error. For the past thousand years, the family systems of the West have been very different from those of China, India, Japan, Africa, or Islam. There has been no clan system or lineage

system in the West, and no ancestor worship has existed. Goode, "Industrialization and family change" (1966), p. 247. See also Greenfield, "Industrialization and the family" (1961).

<sup>166</sup> Goode, *World Revolution and Family Patterns* (1963), pp. 10-26.

<sup>167</sup> However, this effect is not certain since the high negative correlation often found between female activity rates and size of household may merely reflect the fact that women with more children are not free to take employment. Kučera, "Employment of women and reproduction" (1967), p. 26; Jureček, "Diferenční plodnost podle ..." (1966). See also chapter IV, section F.

<sup>168</sup> Musil and Prokopec, "Příspěvek k otázce skladby ..." (1961).

<sup>169</sup> Eversley and Jackson, "Problems encountered in forecasting housing demand ..." (1967), pp. 418-422.

children and their departure from the family, and the later years before the family is finally dissolved. Successive readjustments of behaviour patterns are required as the adult members shift their roles from newly married persons to parents of small children, parents of older children, older couples without children at home and surviving widows or widowers.

138. One of the major contributions of demography to the study of family life has been the development of the concept of "life cycle of the family" and a set of definitions that facilitate comparable research on a national and international basis.<sup>170</sup> Following initial work in the field of rural sociology,<sup>171</sup> Glick contributed greatly to the development of the concept of "life cycle of the family"<sup>172</sup> as a framework for the study of the nuclear family.

139. This orientation provides a means for analysing the changes which take place in the demographic composition and economic characteristics of families from marriage through child-bearing, the stage when children are leaving home, the "empty nest" period, and the final dissolution of the families.<sup>173</sup> In different countries and at different time periods in a single country, marked differences have been observed in the age at marriage, in the size of family at various stages of the life cycle and in life expectancies, and these changes have modified the characteristic ages at which husbands and wives reach the several stages of the family life cycle.<sup>174</sup>

140. The concept of the life cycle of the family has been widely accepted as a framework for various types of analysis of the nuclear family. The merits of applying the family life cycle approach in studying a variety of socio-economic phenomena have been noted.<sup>175</sup> As Lansing and Kish demonstrated, for several variables, such as home ownership, income levels, purchases of consumer durables, cars, savings etc. the family life cycle explains more of the total variations than can be explained by age.<sup>176</sup>

<sup>170</sup> Bogue, *Principles of Demography* (1969), p. 384.

<sup>171</sup> See Loomis and Hamilton, "Family life cycle analysis" (1936); Sorokin, Zimmerman and Galpin, *A Systematic Source Book* ... (1931).

<sup>172</sup> Glick, "The family cycle" (1947); ———, "The life cycle of the family" (1955, pp. 831-844; ———, "The life cycle of the family" (1955), pp. 3-9; ———, *American Families* (1957), chaps. 3-5; Glick, Heer and Beresford, "Family formation and family composition ..." (1963), pp. 37-40; and Glick and Parke, "New approaches in studying the life cycle ..." (1965).

<sup>173</sup> Glick and Parke, "New approaches in studying the life cycle ..." (1965), p. 187.

<sup>174</sup> Besides the sources cited above, see Nelson, *Rural Sociology* (1955), pp. 307-312; Duvall, *Family Development* (1962); Collver, "The family cycle in India and the United States" (1963); Hill and Rodgers, "The developmental approach" (1964); Morioka, "Kazoku no keitai" (1966); ———, "Life cycle patterns in Japan, China and the United States" (1967).

<sup>175</sup> See, for example, Duvall, *Family Development* (1962); David, *Family Composition and Consumption* (1962), especially chap. 3, pp. 20-30; Beyer, *Housing and Society* (1965), p. 259, pp. 282-284; Lansing and Morgan, "Consumer finances over the life cycle" (1955); Fisher, "Family life cycle analysis ..." (1955); Iochi, "Kakei no kahei juyo: (horon)" (1966); Praiss and Houthakker, *The Analysis of Family Budgets* ... (1955).

<sup>176</sup> Lansing and Kish, "Family life cycle as an independent variable" (1957), p. 518.

141. Perhaps, more importantly, this approach can be useful as a tool for shedding light on very complex and still largely unexplored areas of couple fertility patterns and dynamics of family building and it can be linked with the probability models of family building, which have come into use in recent years, with the aid of electronic computers.<sup>177</sup> Indeed, the family life cycle approach will undoubtedly be an integral part of the future development of stochastic demographic models concerning family building and family planning, including not only fertility and mortality factors but also nuptiality and household formation elements. This approach will be helpful for identifying the particular stages of the family life cycle where the introduction of family planning is most effective.

## 2. STAGES IN THE FAMILY LIFE CYCLE

142. The family life cycle may be divided into a few or many stages, depending on the specific interest. It is possible to envisage a two-stage family cycle: (1) the expanding stage, from the inception of the family until the time its children are grown; and (2) the contracting stage when grown children are leaving to establish families of their own.<sup>178</sup> Such a two-stage delineation is usually too crude for most analyses, however.

143. As early as 1931, Sorokin, Zimmerman, and Galpin discussed a four-stage family life cycle based on the changing constellation within the family:<sup>179</sup>

- (1) Married couples beginning their independent economic existence;
- (2) Couples with one or more children;
- (3) Couples with one or more adult self-supporting children; and
- (4) Couples growing old.

144. Many other sequences of the family life cycle have been formulated by family sociologists. The most complex breakdown elaborates twenty-four stages.<sup>180</sup> While such an elaboration may be useful for particular types of research design, it is unnecessarily detailed for

<sup>177</sup> See, for example, Henry, "Fécondité et famille, modèles mathématiques" (1961), pp. 27-46 and pp. 261-262; ———, "Mesure du temps mort en fécondité naturelle" (1964); Bourgeois-Pichat, "Les facteurs de la fécondité non dirigée" (1965), pp. 383-424; Sheps, "Applications of probability models ..." (1965); Sheps and Perrin, "Human reproduction: a stochastic process" (1964); ———, "The distribution of birth intervals ..." (1964); Potter, "Birth intervals: structure and change" (1963); Potter *et al.*, "A case study of birth interval dynamics" (1965); Potter and Sakoda, "A computer model of family building ..." (1966); Ridley and Sheps, "An analytic simulation model ..." (1966); Hyrenius and Adolfsson, *A Fertility Simulation Model* (1964); Vincent, *Recherches sur la fécondité biologique* (1961); Sheps, "Contributions of natality models ..." (1966), pp. 445-449; Matras, "The social strategy of family formation ..." (1965).

<sup>178</sup> Duvall, *Family Development* (1962), pp. 5-6.

<sup>179</sup> Sorokin, Zimmerman and Galpin, *A Systematic Source Book in Rural Sociology*, vol. 2 (1931), pp. 30-32. Generally speaking, studies in the 1930s and 1940s undertaken mostly by rural sociologists divided the cycle into four stages: (1) the pre-child family, (2) the growing family, (3) the contracting family, and (4) the aging family. See Morioka, "Life cycle patterns in Japan, China and the United States" (1967), p. 599.

<sup>180</sup> Rodgers, *Improvements in the Construction and Analysis of Family Cycle Categories* (1962), pp. 64-65.

UNITED STATES OF AMERICA, INDIA (BANARAS) AND JAPAN

Stage	Country				
	United States			India (Banaras)	Japan 1960
	1890	1950	1959		
First marriage .....	22.0	20.1	20.2	14.6	24.4
Birth of first child .....	23.0	21.8	21.6	18.2	26.3
Birth of last child .....	31.9	26.1	25.8	37.0	28.7
Marriage of last child .....	55.3	47.6	47.1	53.0	54.5
Death of husband .....	53.3	61.4	63.6	39.5	69.1

SOURCE: For the United States: Glick, "The family cycle" (1947); ———, *American Families* (1957), pp. 53-70; Glick, Heer and Beresford, "Family formation and family composition ..." (1963), p. 37. For Banaras (India): Collver, "The family cycle in India and the United States" (1963), p. 88. For Japan: Morioka, "Life cycle patterns in Japan, China, and the United States" (1967), p. 605.

Note: The data for the three countries are not strictly comparable because of slightly different definitions of events.

general use. The problems of delineating family life cycle stages suitable universally are many because of the variations in family type from one society to another. Duvall suggests the following stages of the family life cycle:<sup>181</sup>

- (1) Beginning families (married couple without children);
- (2) Child-bearing families (oldest child under 30 months);
- (3) Families with pre-school children (oldest child 30 months to 6 years);
- (4) Families with school children (oldest child 6 to 13 years);
- (5) Families with teen-agers (oldest child 13 to 20 years);
- (6) Families as launching centres (from the time first child leaves until the last is gone);
- (7) Families in the middle years ("empty nest" to retirement);
- (8) Aging families (retirement to death of both spouses).

145. It should be noted that the central concern of Duvall's scheme is children—their ages and attendance at school. Glick and Parke, on the other hand, present a more general, demographic type of family cycle, as shown below:

- (1) Family formation: first marriage;
- (2) Start of child-bearing: birth of first child;
- (3) End of child-bearing: birth of last child;
- (4) "Empty nest": marriage of last child;
- (5) Family dissolution: death of one spouse.<sup>182</sup>

The Glick-Parke family life cycle has been adopted as the standard for various later research studies both within and outside the United States.

### 3. LENGTH OF STAGES IN THE FAMILY LIFE CYCLE

146. Data on family life cycles are extremely scarce for most countries of the world. Four series of family

life cycle data are presented in table X.16 for comparison: the United States for 1890, 1950 and 1959, India (Banaras) for 1956 and Japan for 1960. The series of data for the United States clearly shows that between 1890 and 1959 substantial changes had taken place, tending towards earlier marriage, an earlier start to child-bearing, an earlier birth of last child, an earlier departure of children for homes of their own (an earlier marriage of last child), and a longer period where the couple (father and mother) live in an "empty nest" without co-living children. It is seen that in 1890, the probability was that by the time the last child had married and separated himself from the parental home, the father was already dead, but that in 1959, the father had a chance of surviving 16.5 more years after his last child's marriage.

147. The table also reveals the markedly different patterns of family life cycles in the three countries, as influenced by demographic and cultural conditions. Particularly striking are the disparities found in the length of different cycle stages between the United States and India, the latter showing a much earlier marriage of women, an earlier bearing of the first child, a much longer child-bearing period and a much longer period during which the children remained in the parental household. Moreover, the data for India show that a mother is likely to live as a widow for more than ten years before the marriage of her youngest child.

148. The family life cycle of Japan is characterized by late marriage and birth of first child, and by a surprisingly early termination of child-bearing. In fact, child-bearing is concentrated in a very short period of 2.4 years, since the first child is born on average when the mother is 26.3 years of age and the last at age 28.7 years. In contrast, the Banaras (India) data show the average child-bearing period extending over 18.8 years. Also owing to the substantial increase in longevity among men as well as women in Japan, a parental couple can expect to live together for almost fifteen years after the last child has married and set up his own household.

## G. Summary

149. Studies of demographic aspects of families and households, analyses of their size and composition and of factors affecting them are relatively scarce and largely limited to developed countries. While there has been a great volume of literature dealing with family size, such studies generally refer only to the number of children ever born to a woman or a couple and are not concerned with total family size, including adults as well as children. The literature on family size in the former sense has been discussed in chapter IV; this chapter has considered aspects of the total size and composition of families and households among countries and regions, which are determined not only by the levels and patterns of fertility and mortality and the consequent sex-age structure of population, but also by the levels of nuptiality, and by the degree of doubling-up of families or conversely by the degree of nuclearization.

150. The paucity of demographic studies of families and households is due largely to the lack of pertinent census and survey data. The concept of the headship rate is a key to modern methods of projecting the number of families and households, and it may be a good indicator of the degree of family doubling-up or of the degree of nuclearization. However, aside from the developed countries, only certain Latin American countries, India and Singapore have so far provided census tabulations of heads of families and households classified by sex and age. Furthermore, because most of these countries have collected sex-age-specific headship data only recently, in many cases only since the 1960 round of censuses, it is not possible to undertake historical analysis of changes in headship rates and of their effects on average size of families and households. No country has ever collected "vital statistics" of families and households which register formations and dissolutions of families and households, their growth due to new births and in-migration, and their contractions due to deaths and out-migration. Such data, which would be useful for life cycle analysis of families and households, are at present of only academic interest.

151. It has been seen that the frequency distribution of countries according to their average household size appears to be bimodal, resembling the distribution of countries by current fertility levels (gross reproduction rates). The averages of household size in the developed countries are concentrated in a range between three and four persons, while those of the developing countries are found to be around five persons. These two groups of countries are polarized not only with respect to average household size, but also with respect to the distribution of households by size, degree of nuclearity, levels and age patterns of headship rates, and trends in average household size. Notably absent are countries with very large

average household size. Extended families of very large size have long been considered typical of less modernized societies such as India, Pakistan, traditional China or Tokugawa Japan, but much new empirical evidence with regard to size and form of families and households in developing countries has revealed that the predominance of very large extended families in those societies is not a reality, but largely an ideal type, perhaps confined only to upper strata of the societies.

152. One of the most interesting features of the trends in average household size is that, while all the developed countries with the available historical data have shown secular declining trends in size, a good number of countries in Latin America and South Asia have recently been experiencing substantial increases, reflecting considerable decreases in mortality for the past two decades or so without accompanying fertility declines. These findings indicate, moreover, that the size of mortality decline has been sufficient to offset the effects of the moderate degree of nuclearization which has taken place in many of these developing countries.

153. Because of the small number of countries with available sex-age-specific headship data, conclusions derived from the studies based on such a sample are naturally tentative. Nevertheless, correlation and regression studies generally show some meaningful positive relationships between levels of sex-age-specific headship rates and socio-economic conditions of the countries concerned. At the same time, changes in the size of household have been studied in relation to levels of fertility and mortality, patterns of marriage including age at marriage, variations in family type, and levels of sex-age-specific headship rates. In these studies, it has been clearly shown that historically as well as cross-sectionally, fertility plays the most important part in determining the average household and family size.

154. While overshadowed by other factors, the process of nuclearization nevertheless exerts a more than negligible influence in determining average size of family and household. This process is promoted by internal migration, especially rural-urban migration. In fact, the latter may be the main factor in nuclearization when it occurs on a massive scale, such as in the rapidly urbanizing countries of Latin America and South Asia where deep-rooted extended family traditions otherwise discourage an undoubling of families.

155. Other social and economic factors such as the level of living, degree of industrialization, degree of awareness and need for privacy, and degree of housing shortage (housing availability) are also regarded as important. But their interrelationships are so complex and the available data have been so insufficient for analysis that any meaningful measures of the influences of these factors remain to be seen in the future.

## Chapter XI

### POPULATION AND NATURAL RESOURCES

1. Throughout history, people have been concerned with the relationship between themselves and the land and other natural resources available to them.<sup>1</sup> All historical records attest to this pervading interest, which has found its reflections in oral and written traditions, institutions, philosophy and science.<sup>2</sup>

2. The possible implications of growing human numbers for the man-resource relationship were stressed poignantly in the writings of Malthus about a century and a half ago. The particular view taken by Malthus, however, was not borne out by subsequent developments in various parts of the world, mainly because Malthus failed to foresee the prodigious expansion in the efficiency of resource use and in the substitution of new resources for others, which the continuous unfolding of science and technology has rendered possible.<sup>3</sup> Improved plant-breeding and increased use of fertilizers, combined with irrigation and chemical control of weeds and insects have substantially raised crop yields.<sup>4</sup> Better methods of processing and using raw materials have stretched the usefulness of a given quantity. There have also been new techniques of finding mineral deposits and of mining those which were once inaccessible or of low-grade

nature.<sup>5</sup> Technological change has been the dynamic factor in the declining cost trend for agricultural and mineral products.<sup>6</sup> For these and other reasons, productivity in the United States' resource industries, for example, rose sharply during the period 1870-1960. While the working force in those industries numbered about 7 million both at the beginning and end of this period, its output in real value increased by more than five times.<sup>7</sup>

3. The limitation of the earth's surface for living space appears to constitute the limiting factor as regards the size of population. This is not, however, equivalent to the Malthusian doctrine of scarcity as it was conceived a century and a half ago. Man may eventually undertake to limit his numbers, not by the operation of positive Malthusian checks, but voluntarily. The space limitation is likely to reach a critical level in overcrowded urban areas, despite the abundance of unoccupied land and the technological possibilities for utilizing space above and below the ground and on the seas.<sup>8</sup>

4. National population and production data, so far as population, resources and environment are concerned, do not reveal the full story. Knowledge of the structure and spatial concentration of population is needed.<sup>9</sup>

<sup>1</sup> "Resources", "natural resources", and "Nature" have been conceived in a number of ways. "Nature", with a capital N, as a "unity" in the nineteenth century and before, was considered to have a fundamental ethical and social value and man "in a state of nature" was considered as "naturally good". More recently, these basic questions have been re-formulated in ecological terms, in which a state of ecological balance is distinguished from a development where disturbances can cause irreversible change, having unforeseeable consequences which may jeopardize human existence. More specifically, fear has also been expressed of the rapid depletion of particular essential resources, leading to a re-formulation of the Malthusian dilemma in new terms. Caulfield, "Welfare, economics, and resources development" (1965), p. 572. See also Ackerman, "Population and natural resources" (1966); Bates, "The human ecosystem" (1969), pp. 21-30; and Handler, *Biology and the Future of Man* (1970), pp. 431-473.

<sup>2</sup> Barnett and Morse, *Scarcity and Growth* ... (1963), p. 1.

<sup>3</sup> Landsberg, *Natural Resources for U.S. Growth* ... (1964), p. 3. According to Price, the rate of growth of international science, irrespective of field, may be put at an exponential annual 7 per cent, i.e., doubling about every ten years, over a period of 250 to 300 years, which is much faster than has been the rate of growth in either population or industrialization. Price, "The scientific foundations of science policy" (1965), p. 234.

<sup>4</sup> Brown, "Human food production ..." (1970). According to Brown, the central question is no longer whether we can produce enough food, but what the environmental consequences of attempting to do so are and how many people the biosphere can support without impairment of its operation. See also Brown, "Population, food and the energy transition" (1969). For a discussion of increases in grain yields as a result of the "green revolution", see chapter XII, section C.

<sup>5</sup> McGann, "Technological progress and minerals" (1961), p. 74; Brooks and Krutilla, *Peaceful Use of Nuclear Explosives* ... (1969), pp. 23-43. See the discussion in section D below.

<sup>6</sup> In the United States, the unit cost in agriculture declined by a compound annual rate of 0.4 per cent during 1870-1919, while in the period 1919-1957 it declined by 1.4 per cent a year. As regards minerals, despite the fact that the demand increased perhaps 40 times over the period 1870-1957, the cost of a unit of minerals in 1957 had fallen to a level only one-fifth of that in 1870. The decline in unit costs (which means an increase in productivity) was more rapid in the latter half of the period than in the earlier—a 1.2 per cent per annum drop to 1919, as against 3.2 per cent per annum from 1919 to 1957. See Barnett and Morse, *Scarcity and Growth* ... (1963), chap. 8. See also the Fisher-Potter study, which relates to the 1870-1960 period: Fisher and Potter, "Natural resource adequacy ..." (1969).

<sup>7</sup> Fisher and Potter, *World Prospects for Natural Resources* ... (1964), p. 11. See also Potter and Christy, *Trends in Natural Resource Commodities* ... (1962), particularly pp. 14-15; and Landsberg, Fischman and Fisher, *Resources in America's Future* ... (1963), pp. 11-13.

<sup>8</sup> According to 1960 census data for the United States, 96 million people—53 per cent of the nation's population—were concentrated in 213 urbanized areas that together occupied only 0.7 per cent of the nation's land surface. Quoted by Davis in "The urbanization of the human population" (1965), p. 41.

<sup>9</sup> Fisher has pointed out: "One has to know also a good deal about the distribution of population: how many live in metropolitan regions, and within them in central cities, and how many in non-metropolitan areas ... The tendency towards further concentration in metropolitan regions outside central cities seems certain to

(Continued on next page)

Overcrowding and spatial concentration of population raise many problems of resources and environment (e.g., spillover effects of wastes produced in urban areas and the resulting pollution of air, water and land). There is little indication, however, that the pattern of population distribution will undergo drastic changes in the near future on either a world or national scale. It rather appears likely that there will be an increased concentration of population resulting from coalescence of present nodes. The resource implications of concentration *versus* dispersion of population have already raised several complex questions.<sup>10</sup> Population growth may or may not become a real threat to the social welfare in the advanced developed countries, and if it does it will likely be first manifested in the deterioration of the quality of life<sup>11</sup> rather than as an inadequate rate of growth in material welfare. However, most developing countries, which are embarked upon long-term economic development, are confronted primarily with a severe shortage of capital per head of population. At current high rates of population growth, they can hardly achieve the desired rate of capital formation and the accompanying technological and institutional innovations which are required for the rate of economic growth to which they aspire.<sup>12</sup> It is

(Footnote 9 continued)

continue during the several decades ahead though perhaps not at as rapid a rate as during recent years. All this means that airshed, watershed, and urban solid waste kinds of pollution will be magnified in the future as population concentration continues to build up in metropolitan areas." See Fisher, "Impact of population on resources and the environment" (1971), p. 396.

<sup>10</sup> Two of the questions raised are: (a) whether, from a resource point of view, public policy should attempt to deal with the problems arising from ever-increasing concentration or whether it should seek to bring about a renewed dispersal; and (b) whether society prefers increasing technological innovations, population control, social revolution or some particular combination of these elements. See, among others, Chapman, "Interactions between man and his resources" (1969), p. 37.

<sup>11</sup> The deterioration which is taking place in the United States has been described in this way: "... the penalties for population expansion are far greater in an affluent society than in a marginal economy. This is already painfully evident in the United States. Rising *per capita* real income places decreasingly tolerable burdens upon the environment: vastly increased solid waste, non-degradable detergents, pesticides, containers and trash, more automobiles, thicker traffic, increased CO and CO<sub>2</sub> production, more smog, rapid erosion of fields for airports, highways, parking spaces, and suburbia, rapidly increased water usage for anything but drinking, viz., air-conditioning, swimming pools, metal fabrication, and paper production plants etc., while the same processes accelerate the depletion of all of our non-renewable resources, e.g., oil, iron ore, copper ore etc." See Handler, ed., *Biology and the Future of Man* (1970), p. 909.

<sup>12</sup> In this context, pertinent literature often emphasizes the exponential nature of population growth, which is to say that if a doubling occurs within one time period, successive equal periods would lead to a quadrupling, eightfold growth and so forth, hence an ever more rapid encroachment upon remaining reserves in resources. Actually, in modern times population growth accelerated, hence it grew with even greater momentum than that implied in a constant exponential rate. However, there are reasons to think that acceleration will come to an end and that, thereafter, the actual rates of growth will also diminish as a response to perceived pressures. The growth of a human population, as Maddox puts it, is "much more complicated and subtle than the growth of a population of bacteria in a set of Petri dishes". Maddox, "The doomsday syndrome" (1971), p. 15. Or, as Abelson remarks, "Concern about the population explosion and such matters as pollution has already had profound effects. ... Important segments of the middle and upper-middle classes are talking of a future 'no growth' society".

generally recognized that in these countries a relatively substantial part of resources is invested in education, public health and medical facilities, leaving thus very little to be allocated to the types of industrial investment that could in the long run achieve increased rates of savings, economic growth and population stability. It is said that in developing countries, science and technology and the economic adaptation of their accomplishments have been employed to offset, essentially, the effects of sheer increases in population.<sup>13</sup>

5. The essential global question appears to be what Landsberg has stated in the following manner: "How long can the natural resources of a finite world support growing populations at rising levels of living? Obviously there are physical limits to land surface; to amounts of fresh water moving through the hydrologic cycle ... and to mineral fuels and metallic ores".<sup>14</sup> Ecologically speaking, the question may be whether man can succeed in establishing a dynamic equilibrium with his environment and avoid a destructive imbalance resulting from further exploitation of resources. To meet man's mounting material needs, nature appears to offer only the ordinary rocks, minerals, soil, water, air and sunlight combined with human intelligence and ingenuity.<sup>15</sup> What is not yet known is the potential mineral wealth concealed in the crust of the earth (both continental and sea crust), how much new land can be brought under cultivation, to what degree fresh water supplies can be re-used with safety, and most important, the extent of human ingenuity in the continuous process of technological transformation.<sup>16</sup> The scientific and technological age has provided man with new means to challenge nature.<sup>17</sup> Since

Abelson, "Limits to growth" (1972), p. 1197. In a similar way Barnett argues that "... each future generation will choose its own birth rate. It will do so, not mindlessly as a grasshopper horde without regard for available vegetation ..." Barnett, "Environmental policy and management" (1967), p. 223. For an illustration of the implications of exponential population growth within a "closed system" as described in terms of "feedback loops", see Meadows *et al.*, *The Limits to Growth* (1972), chaps. 1 and 2. See also Nature, "The case against hysteria" (1972).

<sup>13</sup> Fisher and Potter, "Natural resource adequacy ..." (1969), p. 107.

<sup>14</sup> Landsberg, *Natural Resources for U.S. Growth ...* (1964), p. 4.

<sup>15</sup> Tilson, "The earth's crust" (1962), p. 22. See also Brown, *The Challenge of Man's Future* (1954), p. 218.

<sup>16</sup> See Landsberg, *Natural Resources for U.S. Growth ...* (1964), pp. 4-5. See also Tilson, "The earth's crust" (1962), p. 22. Regarding human fertility as related to human ingenuity, Teller has remarked: "Since he [Malthus] made his dire predictions, the rate of population increase has continued to reach higher and higher levels—and so has the standard of living throughout most of the world. It is true that conditions are wretched in many countries, but even where life is hard people are objecting not because they look back to a happier past but rather because they demand a better future—which they know can be realized. Human fertility is undoubtedly great, but so far human ingenuity has proved greater. I suspect that ultimately the population of the earth will be limited not by any scarcity but rather by our ability to put up with each other." Cited in Nolan, "The inexhaustible resource of technology" (1958), p. 66.

<sup>17</sup> White has stated that technology provides the means by which man may ever more effectively challenge nature and has concluded that "... we shall continue to have a worsening ecologic crisis until we reject the Christian axiom that nature has no reason for existence save to serve man". See White, "The historical roots of our ecologic crisis" (1967), p. 1207. In the same way Schaller has said: "For centuries man has attempted to set himself aside from the ecological system ... He is now only beginning to comprehend

(Continued on next page)

technological progress is built into the social processes of modern times, the increasing scarcity of particular resources is apt to foster the discovery and development of alternative resources, not equal in economic quality, but sometimes even superior to those replaced.<sup>18</sup> Scientific advance and technological change have created a virtually unlimited "knowledge bank" for an endless stream of cost-reducing innovations. Technological progress, instead of being the result of chance and lucky discoveries, appears to follow what Myrdal calls the principle of "circular and cumulative causation", or changes fostering further changes in the desired direction.<sup>19</sup>

6. The extent of a country's natural resources constitutes a limitation on the development which it can undergo. Given a country's resources, its rate of development is essentially determined by the behaviour, skill, and institutions of its human population.<sup>20</sup> In the less developed countries where a low rate of resource exploitation generally prevails, economic development tends to be hindered by the high rates of growth of population, which tend to adversely affect the accumulation of capital. As these countries advance in their development, they witness an acceleration in the consumption of their natural resources.<sup>21</sup> The importance of these resources inputs, however, tends to decline relative to total input and total output as economic development advances. This does not imply that the absolute volume of resources requirements declines; it merely means that, with an increase in total output, the total demand for resources inputs may grow less.<sup>22</sup>

(Footnote 17 continued)

that it is not enough to improve the political system or economic system, but that he must reach a healthy relationship with his environment." See Schaller, "Man's ecological environment" (1969), p. 116. Lenin also pointed out that man's new discoveries will increase his mastery over nature. Lenin, *Materializm i empirio-krititsizm* (1961), p. 298. See also Malin, *Zhiznennye resursy chelovechestva* (1967).

<sup>18</sup> "Few components of the earth's crust, including farm land, are so specific as to defy economic replacement, or so resistant to technological advance as to be incapable of eventually yielding extractive products at constant or declining cost. When coal, petroleum, hydroelectric power, and the atomic nucleus replace wood, peat, and dung as source of energy; when aluminum yields its secrets to technology and is made to exist, as never before, in the form of metal; . . . when all this happens, can we say that we have been forced to shift from resources of higher to those of lower economic quality?" See Barnett and Morse, *Scarcity and Growth* . . . (1963), p. 10.

<sup>19</sup> See Myrdal, *Economic Theory and Under-developed Regions* (1957), chap. 2. Medawar remarks in a more general way that: "One of the lessons of history is that almost everything one can imagine possible will in fact be done, if it is thought desirable; what we cannot predict is what people are going to think desirable." See his statement in Wolstenholme, ed., *Man and his Future* (1963), p. 362.

<sup>20</sup> Lewis, *The Theory of Economic Growth* (1955), p. 52.

<sup>21</sup> Fuller, "Natural and human resources" (1959), pp. 2-3.

<sup>22</sup> Adler stresses the effects of the changing structure of production and consumption in the process of economic development as tertiary activities become relatively more important and lead to a decline in the demand for inputs of material resources. See his "Changes in the role of resources at different stages of economic development" (1961), p. 50. According to Potter and Christy, the contribution of the so-called natural resources industries to GNP in the United States has declined from a third of the total in 1900 to some 13 per cent by the late 1950s. Potter and Christy, *Trends in Natural Resource Commodities* . . . (1962), p. 6.

7. In the early 1950s there was considerable fear of natural resource scarcity in the developed countries.<sup>23</sup> By the mid-1960s, however, many of the anxieties over the supply of natural resources appeared to have subsided, as there were few indications pointing to widespread and persistent shortages of materials in the next 20 or 30 years. Instead, the most troublesome problems were of an environmental nature, such as the cleanliness of the air and water, the effects of excessive use of pesticides upon soil and water, the availability of suitable surroundings for outdoor recreation and the effects of urban living upon the human body and spirit.<sup>24</sup> With the concept of the earth as a "spaceship", there has developed over the past few years new awareness of the complex ecological relationship of man to natural resources and environment.<sup>25</sup> Speculations and studies of the effects of environmental deterioration and pollution have included assertions that the accumulation of carbon dioxide from fossil fuel combustion, consequent to population growth and economic development, might warm up the earth's atmosphere and cause the polar ice to melt, thus raising the sea level and submerging coastal cities. There has also been warning of the possibility that particles emitted into the air from industrial and transportation sources

<sup>23</sup> For example, in January 1951, in the United States, President Truman established the President's Materials Policy Commission and entrusted it with the task of inquiring into whether there would be enough food and industrial raw materials at reasonable prices over the next 25 years to support continuing population and economic growth of the country. See United States, President's Materials Policy Commission (Paley Commission), *Resources for Freedom* (1952), 5 vols.

<sup>24</sup> Jarrett, "Editor's introduction" (1966). For detailed discussion see section E below.

<sup>25</sup> Boulding points out: "... in the spaceman economy, throughput is by no means a desideratum, and is indeed to be regarded as something to be minimized rather than maximized. The essential measure of the success of the economy is not production and consumption at all, but the nature, extent, quality, and complexity of the total capital stock, including . . . the state of the human bodies and minds . . . In the spaceman economy, what we are primarily concerned with is stock maintenance, and any technological change which results in the maintenance of a given total stock with a lessened throughput (that is, less production and consumption) is clearly a gain." See Boulding, "The economics of the coming spaceship earth" (1966), pp. 9-10. Gough and Eastlund have stated that "... future societies will be forced to develop 'looped', or 'circular', materials economies to replace their present, inherently wasteful 'linear' materials economies. . . Within these limits, however, the standard of living of the population would be higher if the rate of flow of materials were lower. This . . . could be accomplished in two ways: increasing the durability of individual commodities and developing the technological means to recycle the limited supply of material resources. The conclusion appears radical. Future societies must *minimize* their physical flow of production and consumption. Since a society's gross national product for the most part measures the flow of physical things, it too would be reduced. But all nations now try to *maximize* their gross national product, and hence their rate of flow of materials!" See Gough and Eastlund, "The prospects of fusion power" (1971), p. 50. The spaceship aggregate concept has recently been used to define a world model. The model is a first attempt to bring together the large body of information about causal relationships among five basic quantities or levels—population, capital, food, non-renewable resources and pollution—and to express that information in terms of interlocking feedback loops. The main purpose is to explore the degree to which man's attitude towards continual and accelerated growth—of population, land occupancy, production, consumption, wastes etc.—can be justified. See Forrester, *World Dynamics* (1971), chaps. 2 and 3; and Meadows et al., *The Limits to Growth* (1972), chap. 3, particularly fig. 26.

might prevent some sunlight from reaching the earth's surface, thus lowering the global temperature and beginning a new ice age. Similarly there have been increasing demands to ban DDT, as its effects on reproductive capabilities of birds have been determined, and as evidence is found of its cumulative effects on other species, including man. Serious questions have been raised as to the effects on oceans and terrestrial ecosystems of systematically discharging into the environment such materials as oils and radio-active substances, or nutrients such as phosphorous which can overenrich lakes and coastal areas.

8. "Residual" and "waste", resulting from consumption and production of goods and services, tend to increase as population growth and economic development proceed. They become environmental problems—pollutants—when they have harmful effects in the biosphere.<sup>26</sup> The environmental problem is said to depend upon: (a) the growth of population; (b) the development of technology and its application to natural resources; and (c) the priorities accorded respectively to the first-order effects of technology, and the second-order, third-order, or higher effects of technology (side-effects).<sup>27</sup>

9. From an economic standpoint, the environmental spillovers and the pollution of the atmosphere and water which have at times reached critical levels in recent years in developed countries are considered to be the outcome of the failure of the price system and many of them can be dealt with, at least in part, by corrective taxation.<sup>28</sup>

<sup>26</sup> The pertinent economic aspects of environmental problems and spillovers are that when considered as "external diseconomies" (i.e., those external to the firm but internal to the industry), their effects on the welfare of the population can be substantial. Formerly, economists concerned with environmental pollution had adopted a partial equilibrium approach and treated the pollution of particular environmental media such as air and water as separate problems. Recently, however, it has generally been argued that the production of residuals is an inherent part of the production and consumption processes and that the environmental media which receive and assimilate residual wastes are far from "free goods" but are natural resources of great value. A broad framework is generally considered in which environmental pollution and its control are viewed as a material balance problem for the entire economy. Of the wide literature on this subject, see, for example, Ayres and Kneese, "Pollution and environmental quality" (1969); Buchanan and Stubblebine, "Externality" (1962); Turvey, "On divergences between social cost and private cost" (1963); Ridker, *Economic Costs of Air Pollution* . . . (1967); Worcester, "Pecuniary and technological externality . . ." (1969); Mishan, "The postwar literature on externalities . . ." (1971); Fisher, "Impact of population on resources and the environment" (1971); Leontief, "Environmental repercussions and the economic structure . . ." (1970); Kneese, "Environmental pollution . . ." (1971); and Solow, "The economist's approach to pollution and its control" (1971).

<sup>27</sup> Matthews, *Man's Impact on the Global Environment* . . . (1970), pp. 224-226.

<sup>28</sup> A number of methods have been suggested for influencing production so as to reduce or eliminate external diseconomies of this type. Most familiar are: (a) outright prohibition; (b) regulation of production of goods generating externalities; (c) voluntary agreements; and (d) subsidy and tax methods, which, until recently, was the favoured solution. For a discussion of these and other methods, see Davis and Kamien, "Externalities, information and alternative collective action" (1969); Mishan, "The postwar literature on externalities . . ." (1971); Princeton University, Center of International Studies, *Ecology and Politics in America's Environmental Crisis* (1970), pp. 109-110; and Coale, "Man and his environment" (1970).

The immediate problems facing human population are generally recognized to be those relating to pollution rather than the depletion of natural resources.

10. Sections A and B of this chapter focus attention on important questions of definition, classification, and measurement of natural resources and briefly review recent opinions and doctrines hereto advanced. The classification of natural resources is discussed in detail in section C. The determinants of the demand for and supply of natural resources are considered in sections D and E, and finally, the relation of natural resources and population to development in section F.

#### A. Concept of natural resources and problems of measurement

11. It is generally recognized that the material level of living of the population of an area depends on several factors: natural resources; human resources, including *entrepreneurs*, management and the labour force; capital resources such as industrial plants, transportation facilities and housing; and institutional resources, such as science and technology, laws, social structure, and the educational system. It is difficult to isolate these fundamental factors. Thus, natural resources, before they take on economic significance, must have capital, labour and technology applied to them.<sup>29</sup>

12. The concept of natural resources has changed from time to time and from place to place. The role of technology is particularly important in defining natural resources. In fact, resources availability in time can hardly be defined but in terms of technology.<sup>30</sup> Since technology changes constantly and unpredictably over time, the definition and measurement of resources undergo constant changes, with the consequence that a static, well-defined quantitative limit to natural resources becomes untenable. Accordingly, when an area is said to be richly endowed in any of the natural resource categories,<sup>31</sup> the statement is empirically meaningful only in relation to a given time and a given state of knowledge and technology.<sup>32</sup> Similarly, an area which is poorly endowed in natural resources today may be considered rich in resources at some later time, not merely because unknown resources are discovered, but also because new uses are discovered for the known resources.<sup>33</sup>

13. The pioneering report of the United States President's Materials Policy Commission approached the

<sup>29</sup> Fisher, "The relationship of material resources and population to economic and social development" (1967), p. 313. See also Gurvich, *Rol' prirodnikh bogatstv* . . . (1961), pp. 20-21.

<sup>30</sup> Coal was not a valued natural resource until men learned to burn it; neither can anyone speak with certainty today as to its value in two hundred years' time. Lewis, *The Theory of Economic Growth* (1955), p. 52. Half a century ago, the air was for breathing and burning. But since 1913, as a result of the development of the Haber process by which the extraction of nitrogen from the air became feasible, the atmosphere has been promoted to an important natural resource. See Barnett and Morse, *Scarcity and Growth* . . . (1963), p. 7.

<sup>31</sup> See section D below.

<sup>32</sup> Lewis, *The Theory of Economic Growth* (1955), p. 52.

<sup>33</sup> United States, President's Materials Policy Commission, *Resources for Freedom*, vol. 1 (1952), chap. 4. See also Putnam, *Energy in the Future* (1953).

concept of resource scarcity more in terms of cost than of physical depletion, since there is no case in history in which a material has totally run out, except in a given location.<sup>34</sup> Long before any possible exhaustion, and in the absence of technology, difficulties will arise in the form of persistently increasing costs because new deposits

<sup>34</sup> McDivitt stated: "There is no recorded history of mankind running out of the supply of one or the other mineral . . . there is no shortage of minerals in the world today and there is no indication of shortage in the foreseeable future. . . . Past shortages have been due to inability to keep up with sudden surges in demand rather than to any basic lack of natural resources—due, that is, to inadequacy in plant, not of raw materials." See McDivitt, *Minerals and Men* . . . (1965), p. 10. See also Landsberg's statement: "There is abundant oil in the shales and tar sands of the North American continent; abundant aluminum in the crust of the earth everywhere; abundant manganese and other metals in the nodules that cover much of the ocean floor; abundant timber in virtually untapped tropical forests. The crucial question usually is not how much there is of needed resource materials, but what it will cost to extract and put them to use." Landsberg, *Natural Resources for U.S. Growth* . . . (1964), p. 5. Also, "Today, some 500 million tons of material must be handled to produce the major domestic metals; some 10 billion tons might have to be moved if we wanted to recover our metal needs from average rock. Because such great masses of minerals are contained in the crust of the earth, scarcity and depletion are less physical concepts than economic ones." *Ibid.*, p. 199. Brown asserts that "one hundred tons of average igneous rock contain, in addition to other useful elements, 8 tons of aluminum, 5 tons of iron, 1,200 pounds of titanium, 180 pounds of manganese, 70 pounds of chromium, 40 pounds of nickel, 30 pounds of vanadium, 20 pounds of copper, 10 pounds of tungsten and 4 pounds of lead". Given adequate supplies of energy, these elements can be extracted from the rock and it appears likely that the rock itself contains the requisite amount of energy in the form of uranium and thorium. Brown concludes that the "basic raw materials for the industries of the future will be sea-water, air, ordinary rock, sedimentary deposits of limestone and phosphate rock, and sunlight". Brown, *The Challenge of Man's Future* (1954), pp. 217-218. See also his "Technological denudation" (1956). Barnett and Morse have noted: "Advancing ocean technology could conceivably lead to a 'steady state' equilibrium of a great circular flow process analogous to, but far more complex than, the carbon dioxide cycle. Equally important are the energy plateaux already created by atomic fission and eventually, perhaps, to result from nuclear fusion and solar energy devices. Once energy becomes available in unlimited quantities at constant cost, the processing of large quantities of low-grade resource material presumably can be undertaken at constant cost without further technological advance, and at declining cost with technological advance and capital accumulation." Barnett and Morse, *Scarcity and Growth* . . . (1963), p. 239. Brown, Bonner and Weir state that "... from the technological point of view, we see that fundamentally there is no lower limit to the grade of an ore which can be processed. This was illustrated dramatically by the isolation of the new element plutonium . . . the ultimate resources of energy which are available to man are enormous—and indeed are sufficient to power a highly industrialized world for literally millions of years. This means that, given adequate brainpower, there is little doubt that the trend which has led us to process ores of steadily decreasing grade can continue until we reach the point where we are processing the very rocks of which the earth's crust is made." They further remark that: "... man has available potential sources of energy which are sufficient to satisfy his needs for a very long time. However, these resources have yet to be transformed from potential supplies into actual ones. Before they can be used they must be developed. Whether or not man will be able to develop them in time is a very real question, the answer to which will be determined, in the long run, by many factors of a political, economic, and social nature," and finally, in conclusion, they state "... it appears that the critical limiting factor as far as the world's resources are concerned is not materials, energy, or food, but brainpower." Brown, Bonner and Weir, *The Next Hundred Years* . . . (1957), pp. 90-91, 112, 115. See also California Institute of Technology, *The Next Ninety Years* . . . (1967).

tend to become harder to exploit or because the quality of the deposits found is deteriorating.<sup>35</sup> If the costs of obtaining scarce natural resource products should rise significantly in relation to other costs, society would be devoting larger shares of manpower and capital for their production. Rising real cost would then become a drag on the continued improvement in the average level of living of populations.

14. Chapman has expressed the view that in the human ecosystem, man assigns utility to various elements of his environment and thus confers upon them the role of resources. Resources then are neither wholly of the physical world nor wholly of the world of man but are the result of the interaction between the two.<sup>36</sup> Others have stated that since man's economic activity consists in combining the agents of production (natural resources, labour and capital) to create utilities, natural resources can be defined as "an arrangement of matter to which man can apply his activities to increase his net welfare".<sup>37</sup> Zimmermann's dynamic functional definition of natural resources is based on the trinity of "nature, man and culture". Resources are dynamic not only in response to increased knowledge and expanding science and technology, but also in response to changing individual wants as well as social objectives.<sup>38</sup>

15. Perloff and others have introduced the new concept of "environmental resources" as distinct from the traditional commodity resources. Included are such "amenity resources" as climate, topography, coast and sea-shore, which may influence the location of economic activities or family residence, as well as open space areas, particularly on the outskirts of cities, that are attractive for recreation purposes.<sup>39</sup> In the United States, according to Perloff, the concept of natural resources is strongly influenced by the

<sup>35</sup> New technology can, however, prevent such a trend. For example, Herfindahl found that the deflated price of copper had remained fairly constant for long periods since 1870 in the United States, despite the fact that the average grade of copper ore decreased from 3 to 1 per cent. The important offsetting elements involved were the technological improvements, from mining down to finished products. Herfindahl, *Copper Costs and Prices* . . . (1959), pp. 202, 224; and his *Three Studies in Minerals Economics* (1961), p. 32 and fig. 9.

<sup>36</sup> Chapman further states: "The environmental elements that man calls upon to serve as resources, and the nature and size of the requirements he places upon them, depend on his numbers, his needs and desires, and his values and skills". See his "Interactions between man and his resources" (1969), p. 31.

<sup>37</sup> Schaefer and Revelle, "Marine resources" (1959), p. 74. More explicitly it has been stated by these authors that man "neither creates nor destroys matter . . .; he simply rearranges it for his own benefit. He normally accomplishes this only when the application of labor and capital to the naturally occurring arrangement of matter is 'profitable'; that is, more utilities are created than are consumed." *Ibid.*

<sup>38</sup> "Resources are highly dynamic functional concepts; they are not, they become, they evolve out of the triune interaction of nature, man and culture, in which nature sets outer limits, but man and culture are largely responsible for the portion of physical totality that is made available for human use." See Zimmermann, *World Resources and Industries* . . . (1951), pp. 814-815.

<sup>39</sup> Perloff, "A framework for dealing with the urban environment . . ." (1969), p. 5. See also Perloff and Wingo, "Natural resource endowment and regional economic growth" (1961), p. 197; and Fisher, "Impact of population on resources and environment" (1971), p. 392.

conservation movement in the early part of this century which placed great emphasis on the trinity of "conservation, development and use of natural resources".<sup>40</sup>

### B. Recent views on natural resources

16. A substantial number of scholars from a variety of scientific disciplines have expressed concern about the increasing scarcity of natural resources in the light of rapid population growth. Their concerns are essentially derived from the general premise that natural resources are scarce and that the scarcity increases with the passage of time leading to diminishing incremental returns, thereby adversely affecting the welfare of the population. This view, however, is not shared by a sizable number of scholars who are skeptical about accepting the thesis in the absence of sufficient evidence. A review of the existing literature on the subject reveals a multiplicity of propositions that are not always self-evident and factual, but are often based on speculation and hypotheses.

17. The past two centuries—the period characterized by the emergence of modern science, the industrial revolution and accelerating population growth—have witnessed a great interest in the relation of population to material resources.<sup>41</sup> This was rather systematically explored early in the nineteenth century by British classical economists, most of whom based their studies on the Malthusian theory of population and took the view that the limited availability of natural resources sets an upper limit to economic growth and welfare of population. Malthus' doctrine stated that population tends to outrun the means of subsistence—mainly land and farm products—subject to the constraint of positive (famine etc.) and preventive (birth control etc.) checks.<sup>42</sup> Ricardo,

<sup>40</sup> Perloff, "A framework for dealing with the urban environment . . ." (1969), pp. 7-8. See also Perloff *et al.*, *Regions, Resources and Economic Growth* (1960).

<sup>41</sup> Population questions also attracted interest in early times, though they were not closely linked to economic concerns or the availability of food. For the views of early Greek and Roman writers on population, see chapter III, section A. After about the sixteenth century, writers began to stress economic considerations in relation to population. See chapter III, section B. See also Mayer, "Toward a non-Malthusian population policy" (1969), pp. 5-6; Spengler, *French Predecessors of Malthus* . . . (1942); Wrigley, *Population and History* (1969), chaps. 2 and 3; and Langer, "Checks on population growth . . ." (1972).

<sup>42</sup> Malthus, *An Essay on the Principle of Population* . . . (1798; 1970 ed.). Malthus' *Essay* is far from a complete logical proposition such as that in a modern scientific model, of the relation of natural resources to population. However, the qualified Malthusian theory (applied to a population closed to trade, migration and technology from abroad) may historically be considered as tested and verified by the classical example of Ireland. The population of Ireland increased during the latter part of the eighteenth and the first half of the nineteenth centuries as food production increased, but thereafter a sharp decline, originating in the potato famine, set in. See the discussion in chapter II, section D. For a recent interpretation of the Malthusian doctrine, see Flew, "Introduction" (1970). Barnett and Morse have constructed an analytical model based on population and natural resources consistent with the intent of Malthus. Four variables have been included in the model: (1) time and population, (2) natural resources availability, (3) technology and institutions, and (4) the production process. Barnett and Morse, *Scarcity and Growth* . . . (1963), pp. 54-58. For the technical discussion and details of the model, see Morse and Barnett, "A theoretical analysis of natural resource scarcity . . ." (1961).

who considered mineral production as well as agriculture, modified Malthus' doctrine of scarcity by maintaining that the real threat was one of the progressive decline of resource quality because the richest farmland and beds of ore would be used first.<sup>43</sup> Mill accepted Malthus' principle of population, but he believed that social reforms and other improvements could lead to economic progress. He also broadened the scope of natural resource scarcity to include living space and the quality of life.<sup>44</sup>

18. About the turn of the century the Conservation Movement in the United States had a vigorous impact on public opinion.<sup>45</sup> The 1908 United States Governors' Conference and the communications of the Inland Waterways Commission provided literally thousands of estimates of the physical quantities and characteristics of natural resources.<sup>46</sup> These estimates gave finite amounts for coal, iron and other minerals as well as the dates when they would be exhausted.<sup>47</sup>

19. The recent body of literature on the relation of natural resources to population is voluminous. Some prominent contemporary conservationists believe that, within the foreseeable future, an increasing consumption of resources might produce scarcities, causing a lowering

<sup>43</sup> Ricardo, *The Principles of Political Economy and Taxation* (1817; 1911 ed.), pp. 34-35, 46-47.

<sup>44</sup> Mill, *Principles of Political Economy* . . . (1848; 1965 ed.), particularly pp. 157 ff. See also the discussion in chapter III, section D.

<sup>45</sup> The meaning of "conservation" varies from author to author and from time to time. Barnett and Krutilla have shown that its root lies in Malthusian thinking and the exhaustion of natural resources. Herfindahl, examining the writings of the Conservationists since Gifford Pinchot, the virtual founder of the Movement, found that conservation had been associated with many conflicts and inconsistencies. Among factors intensifying these conflicts, he noted the growth of population with its effects on increased demands for the use of natural resources. Herfindahl, *What is Conservation?* (1961), particularly p. 9. See also Krutilla, *Conservation Reconsidered* (1967); Mason, "The political economy of resource use" (1958), pp. 157-162; Scott, *Natural Resources* . . . (1955); Ciriacy-Wantrup, *Resource Conservation* . . . (1963) and his "Economics and policies of resource conservation" (1959); National Academy of Sciences—National Research Council, *Principles of Resource Conservation Policy* . . . (1961), pp. 1, 3-4.

<sup>46</sup> The communications of the Inland Waterways Commission to President Theodore Roosevelt, which led to the Conference, called attention to an unprecedented consumption of natural resources and exhaustion of these resources. President Roosevelt, in accepting the view, declared " . . . there is no other question now before the nation of equal gravity with the question of the conservation of our natural resources. . . . It is evident the abundant natural resources on which the welfare of this nation rests are becoming depleted and, in not a few cases, are already exhausted". See United States, Committee of Governors, *Proceedings of a Conference of Governors* . . . (1909), p. x. The idea of resource depletion was widely accepted and appears to have dominated the Conference deliberations.

<sup>47</sup> Pinchot, who shared with President Roosevelt the leadership of the Movement, stated: "The five indispensable essential materials in our civilization are wood, water, coal, iron, and agricultural products. . . . We have timber for less than thirty years at the present rate of cutting. The figures indicate that our demands upon the forest have increased twice as fast as our population. We have anthracite coal for but fifty years, and bituminous coal for less than two hundred. Our supplies of iron ore, mineral oil, and natural gas are being rapidly depleted, and many of the great fields are already exhausted. Mineral resources such as these when once gone are gone forever." Pinchot, *The Fight for Conservation* (1910), pp. 123-124.

of the level of living of the population.<sup>48</sup> Others, such as Vogt and Osborn, have warned that unless population were reduced, there would be great risk of a drastic lowering of the level of living.<sup>49</sup> Vogt's argument is based on the adjustment of "demand to supply", that is, a choice between a lower *per capita* income and living standard or fewer people.<sup>50</sup> Osborn also urges restrained population increase on the ground of "relatively fixed" natural resources.<sup>51</sup> One of the most pessimistic of recent writers is Ehrlich, who believes that famine will be rife in the 1970s and hundreds of millions of people will die of starvation.<sup>52</sup>

20. Some physical scientists have investigated the question of the interactions of population and natural resources. Their conclusions cover a spectrum from the pessimistic views of Vogt and Osborn to the optimistic views of Mather. Among the pessimistic views are those of C. G. Darwin and Alan Gregg.<sup>53</sup> Some authors have gone so far as to predict doomsday by either deductive or intuitive and visionary methods.<sup>54</sup> On the optimistic

side, among others, von Neumann speculated that within decades "... energy may be free ... with coal and oil used mainly as raw materials for organic chemical synthesis ...".<sup>55</sup> Others, finding the alarmist views in error because of their disregard of technological changes, have suggested that the long-term solution of energy problems, for food as well as power and fuel, would be found in solar energy.<sup>56</sup> Mather, who wrote towards the end of the Second World War, went further, stating that "Mother Earth can provide food enough" for all people.<sup>57</sup> Some scientists have also insisted that the human species had a vital stake in the extension of the cosmic frontier in order to gain access to new resources on other planets.<sup>58</sup>

21. Some scholars have considered that rapid population growth plays a less important role than other factors in creating pressure on resources and on the available land. According to Juniper, the principal pressure is said to be the result of the increased standards of individual affluence and leisure time.<sup>59</sup> Others have been concerned

<sup>48</sup> See Ordway, *Resources and the American Dream* ... (1953), particularly pp. 26, 35, 47. Similar views are held by other contemporary conservationists such as Leopold, *A Sand County Almanac* ... (1949), and Sears, "Ethics, aesthetics and ..." (1958).

<sup>49</sup> Vogt, *Road to Survival* ... (1948); Osborn, *Our Plundered Planet* (1948); his *The Limits of the Earth* (1953); and his "The world resources situation" (1950); Sax, *Standing Room Only* ... (1955); and Massingham and Hyams, *Prophecy of Famine* ... (1953).

<sup>50</sup> Vogt, *Road to Survival* ... (1948), p. 265.

<sup>51</sup> Osborn has stated: "We are under the power of a timeless principle, exerting its influence relentlessly on a global scale. This principle ... finds expression in a simple ratio wherein the numerator can be defined as 'resources of the earth' and the denominator as 'numbers of people' ... The denominator is subject ... to control by man. If we are blind to this law, or delude ourselves into minimizing its power, of one thing we can be assured—the human race will enter into days of increasing trouble, conflict and darkness." Osborn, *The Limits of the Earth* (1953), p. 207.

<sup>52</sup> Ehrlich, *The Population Bomb* (1968), prologue.

<sup>53</sup> Darwin believed that society has a tendency to breed without limit. He further stated that the intellectually poor stock tends to breed at higher rates, with the result that the weak will fill the earth. Darwin, *The Next Million Years* (1952), particularly pp. 152-153. Borgstrom asserted that the world is "... on the verge of the biggest famine in history ... Such a famine will have massive proportions and affect hundreds of millions, possibly even billions ... The most disquieting aspect of this particular food issue is the fact that with few exceptions the scientific and technical community has been signaling green light to mankind, when red signals are far more appropriate ... Whatever happens, whatever urgent measures we may take, food is going to be the overriding issue of this crucial century." Borgstrom, *Too Many* ... (1969), pp. 317-318. Gregg said that: "There is an alarming parallel between the growth of a cancer in the body of an organism and the growth of human populations in the earth's ecological economy." Gregg, "Is man a biological cancer?" (1955), p. 74. Similar pessimistic views expressed by various scientists were reported in the seven substantive volumes of the United Nations symposium on conservation. United Nations, *Proceedings of the United Nations Scientific Conference* ... (1950). The generally pessimistic outlook adopted by the United Nations Conference as regards resources has been interpreted by the editors of *Nature* as a means to "... further stir the consciences of the developed nations and mobilize greater international aid for the developing countries ...", "Should Malthus be disinterred ...?", *Nature* (1968), p. 214.

<sup>54</sup> Foerster and others, on the basis of a static mathematical model, deduced that on Friday, 13 November A.D. 2026, the population of the world would squeeze itself to death; von Foerster, Mora and Amiot, "Doomsday ..." (1960), p. 1291. Other scholars calculated exactly how large human population can ultimately grow

and how great the pressure on natural resources will then be. Watt, *Ecology and Resource Management* ... (1968), pp. 12-17; and Kleiber, *The Fire of Life* ... (1961), chap. 19. The Ehrlichs stated: "The explosive growth of the human population is the most significant terrestrial event of the past million millenia ... Armed with weapons as diverse as thermonuclear bombs and DDT, this mass of humanity now threatens to destroy most of the life on the planet. Mankind itself may stand on the brink of extinction; in its death throes it would take with it most of the other passengers of Spaceship Earth. No geological event in a billion years—not the emergence of mighty mountain ranges ... nor the occurrence of periodic glacial ages—has posed a threat to terrestrial life comparable to that of human population." They further asserted: "Spaceship Earth is now filled to capacity or beyond and is running out of food." Ehrlich and Ehrlich, *Population, Resources, Environment* ... (1970), pp. 1, 3; see also Ehrlich, *The Population Bomb* (1968); Taylor, *The Doomsday Book* ... (1970); Dubos, *Reason Awake* ... (1970), and his *So Human an Animal* (1968); Dorst, *Before Nature Dies* (1970); and the collection of Helfrich, ed., *The Environmental Crisis* ... (1970), particularly the introduction and the papers contributed by Cole and Borgstrom.

<sup>55</sup> Von Neumann, "Can we survive technology?" (1955), p. 37; see also Wick, "Prophet of nuclear power" (1972).

<sup>56</sup> Thomson, *The Foreseeable Future* (1955); Stamp, *Land for Tomorrow* ... (1952); Rosin and Eastman, *The Road to Abundance* (1953) especially part 2; Smith and Chapin, *The Sun, the Sea, and Tomorrow* ... (1954); United Nations, *New Sources of Energy and Economic Development* ... (1957); ———, *New Sources of Energy and Energy Development* ... (1962).

<sup>57</sup> Mather concludes, "Mother Earth can provide food enough and to spare so that ... every member of the world-wide human family may be adequately nourished. There is no prospect that the press of population will ever place an impossible burden upon the available sources of food or of the organic materials required in industry." Mather, *Enough and to Spare* ... (1944), pp. 69-70. Alvin Weinberg, director of Oak Ridge National Laboratory, has stated "... there is no resource problem. Some substitutions, adjustments, and compromises will be inevitable, and much expensive recycling of scarce substances must be done; but the key requirements appear to be available." Cited by Wick, "Prophet of nuclear power" (1972).

<sup>58</sup> See, for example, Lederberg, "Exobiology: approaches to life beyond the earth" (1966), particularly p. 134.

<sup>59</sup> Juniper states: "It is widely, but erroneously, assumed that were our population stabilized at, say, the 1900 figure no problems of vandalism, waste disposal, air and water pollution, housing pressures on land and all the other nastiness associated with industrial societies would arise. They would, in fact, all occur, but at a marginally lower rate. The principal pressures are industrial demands; ever increasing standards of individual affluence and

(Continued on next page)

with the extent of the disproportionate affluence prevailing in developed and developing countries around the world. They argue that the richer countries tend to consume more natural resources, disturb the ecology more and are capable of causing more pollution of air, land and water than are the poorer countries.<sup>60</sup>

22. Another approach to the man-resources relationship, with some antecedents in the conservation doctrine, but developed mainly by biologists, is the ecological approach. Ecologists study the interdependence of plants and animals as they exist in nature and the relations of each to their environment. The scope of human ecology, which is concerned in general with the interrelationships between human beings and their environment, is less clearly defined and has been interpreted differently by different scholars.<sup>61</sup>

23. A few economic studies of a theoretical nature have considered that the time distribution of resource use and investment under free enterprise conditions may not necessarily be "optimum" and for the "greatest general good".<sup>62</sup> Ise found that the time distribution of resource utilization in the United States was skewed and biased towards the present with a threat of poverty for future generations. Scott and Ciriacy-Wantrup are, however, less convinced of such extreme maldistribution of resources through time; they none the less are of the opinion that national prudence requires appropriate public policies for the protection of the future population.<sup>63</sup> Barnett and Morse, on the other hand, on the basis of analysis of historical data and the multiplier effect of technological changes, have argued that the reservation of resources for later use would contribute little to the welfare of future generations. The natural environment, they declare, is only part of what one generation passes on to another; knowledge, technology,

capital accumulation and economic institutions, which are the determinants of the real income *per capita*, are very likely to be more significant to future generations. Resource reservation, by limiting output and thereby research and development, education and investment, might even diminish the value of the social heritage.<sup>64</sup>

24. Some economists have regarded the growth of population as a factor responsible for the deterioration of the general relation of natural resources to economic welfare.<sup>65</sup> Pigou believed that an efficiently operating *laissez-faire* economy may fail to maximize the social benefit.<sup>66</sup> A number of "Malthusian trap models", characterized by fixed resources (particularly land) and significant rates of population growth have been conceived. These models illustrate that an increase in *per capita* income tends, generally, to further increase population.<sup>67</sup>

25. The interrelationship of natural resources and population growth is not generally considered as an essential part of demography. However, many demographers have expressed pessimism as to the adequacy and capability of natural resources to support current rates of growth of population and consumption *per capita*.<sup>68</sup> On the basis of a new concept of optimum

(Footnote 59 continued)

leisure time, increased energy requirements, the spread of democratic principles and above all, the invention of the car." Juniper, "Laissez-faire..." (1967), p. 1049.

<sup>60</sup> See, for example, Mayer "Toward a non-Malthusian population policy" (1969), pp. 12-13.

<sup>61</sup> McKenzie, *On Human Ecology* (1968), pp. 3-4; Duncan, "Human ecology and population studies" (1959), pp. 678-679.

<sup>62</sup> Hotelling, for example, concentrating on mineral resources, asks: "Is it more profitable to complete the extraction within a finite time, to extend it indefinitely in such a way that the amount remaining in the mine approaches zero as a limit, or to exploit so slowly that mining operations will not only continue at a diminishing rate forever but leave an amount in the ground which does not approach zero? Suppose the mine is publicly owned. How should exploitation take place for the greatest general good, and how does a course having such an objective compare with that of the profit-seeking entrepreneur?" Hotelling, "The economics of exhaustible resources" (1931), p. 139. Heady, on the other hand, is concerned with agricultural land and investment. He states that "... funds should be given allocative priority between soil associations in terms of their marginal productivity in the relevant future time period. Each increment of investment in monetary or technical assistance should be spent in a manner which minimizes the diminution of future production (owing to erosion or other processes which permanently lower productivity)." Heady, "Efficiency in public soil-conservation programs" (1951), p. 51. See also Rothenberg, *An Approach to the Welfare Analysis* ... (1967), particularly chap. 3.

<sup>63</sup> Ise, "The theory of value as applied to natural resources" (1925); Scott, *Natural Resources* ... (1955), chap. 2; Ciriacy-Wantrup, *Resource Conservation* ... (1963); and his "Economics and policies of resource conservation" (1959).

<sup>64</sup> Barnett and Morse, *Scarcity and Growth* ... (1963), pp. 248-249; see also Nolan, "The inexhaustible resource of technology" (1958). Moore states: "To hoard resources unthinkingly in the name of conservation is to misunderstand completely the nature and scope of technological change." Moore, "Unlocking new resources" (1959), p. 138; see also Barnett, "Population problems—myths and realities" (1971).

<sup>65</sup> See, for example, Spengler, "Aspects of the economics of population growth—part II" (1948); and his "Social and economic factors influencing environment" (1961). Boulding looks at the problem in a novel way: "... if the society towards which we are developing is not to be a nightmare of exhaustion, we must ... develop a new technology which is based on a circular flow of materials such that the only source of man's provisions will be his own waste products. In a spaceship there are neither mines nor sewers, and man has to find a place for himself provisioned by a circular flow of materials which happens to take a form unusually favourable to him in the place that he happens to occupy. There is no way, of course, thanks to the dismal second law of thermodynamics, that a circular system of this kind can be achieved without inputs of energy. From the human point of view, fortunately, the energy input from the sun can be regarded as virtually inexhaustible ..." Boulding, *Economics as a Science* (1970), p. 147.

<sup>66</sup> Pigou states that "... there is wide agreement that the State should protect the interests of the future in some degree against the effects of our irrational discounting and of our preference for ourselves over our descendants." Pigou, *The Economics of Welfare* (1932), p. 29. Mitchell has also expressed the same view: "The appalling wastes of natural resources that are going on seem due largely to the policy of handing over the nation's heritage to individuals to be exploited as they see fit. It appears that business planning takes, and must take, a relatively short period of time into account—a period that is but as a day in the life of the nation. What is rational on the basis of this short-run private view may be exceedingly unwise on the basis of long-run public interest." Mitchell, *The Backward Art of Spending Money* ... (1937), p. 89.

<sup>67</sup> See the discussion of the works of Nelson, Leibenstein and Hagen in chapter III, section H.

<sup>68</sup> Robert Cook has said that: "Next to the atom bomb, the most ominous force in the world today is uncontrolled fertility. Unbalanced and unchecked fertility is ravaging many lands like a hurricane or a tidal wave ... The scramble for bare subsistence by hordes of hungry people is tearing the fertile earth from the hillsides, destroying forests and plunging millions of human beings into utter misery." Cook, *Human Fertility* ... (1951), p. 5. On the question of how many persons can live in the United States, Price

(Continued on next page)

population, Cloud considered that the present world population of 3,500 million, as well as the United States population of more than 200 million, both exceed the optimum.<sup>69</sup>

26. Intensive systematic studies carried out in the United States in the early 1950s revealed that there was scarcely a metal or mineral fuel of which the quantity used in the United States since the outbreak of the First World War did not exceed the total used throughout the world in all the centuries preceding.<sup>70</sup> Although concern was expressed over growth of demand for natural resources, no specific recommendation was made to restrain the growth of resource use in the future.<sup>71</sup>

27. In order to keep up with a rapid rate of growth of population, some authors have expressed the view that resource utilization ought to undergo some radical changes in form, which could be translated into either a more effective organization or through a new and revolutionary technique.<sup>72</sup>

### C. Classification of natural resources

28. Natural resources have been classified in various ways according to the objectives of different authors' inquiries.<sup>73</sup> The following classification appears, for the present purpose, most convenient:

(Footnote 68 continued)

stated: "If people are willing to live in dormitory fashion and to get food from algae and other 'artificial' sources, then the population of the United States can continue to increase for many years; but if the people wish to live in single family houses, to eat steak, fresh vegetables, and apple pie . . . to drive their own cars rather than use commercial transportation . . . then the upper limit of population is approaching". Price, "Introduction" (1967), p. 3.

<sup>69</sup> He defined optimum population as one that is "large enough to provide the diversity, leisure, and substance whereby the creative genius of man can focus on the satisfactory management of his ecosystem, but not so large as to strain the capabilities of the earth to provide adequate diet, industrial raw material, pure air and water, and attractive living and recreational space for all men, everywhere, into the indefinite future". United States Congress, *Effects of Population Growth on Natural Resources* . . . (1969), p. 4.

<sup>70</sup> United States, President's Materials Policy Commission, *Resources for Freedom*, vol. 1 (1952), p. 5. As an outcome of these studies, it was proposed that the resource situation of the United States could be improved, *inter alia*, through technological advances which could lead to an expansion of domestic supplies, by shifting from scarce materials to more abundant ones and by obtaining more materials from abroad. *Ibid.*, p. 8.

<sup>71</sup> United States, President's Materials Policy Commission, *Resources for Freedom*, vol. 1 (1952).

<sup>72</sup> See Lent, *Food Enough for All* (1947); Rosin and Eastman, *The Road to Abundance* (1953), pp. 55, 65-66; Smith and Chapin, *The Sun, the Sea, and Tomorrow* . . . (1954); and Herber, *Our Synthetic Environment* (1962), p. 201.

<sup>73</sup> There are a number of classifications of natural resources such as: (1) *renewable* versus *non-renewable resources*: despite strong preference of some scholars for this classification, the distinction is difficult to make in the long run, since, as Kindleberger says, erosion can ruin croplands and prairies, and new reserves of "exhaustible" resources can be brought into use through greater capital investment. Kindleberger, "International trade and investment . . ." (1961), p. 154; (2) *stocks* versus *flow resources*: some resources are exhaustible (e.g. oils, metals) while others are permanent and inexhaustible and their services flow at a certain rate through time (e.g. waterpower and sunlight). For these distinctions and other classifications of resources, see, for example, Hammar, "Society and conservation" (1942), pp. 110-115; Ciriacy-Wantrup, *Resource Conservation* . . . (1963), pp. 42-43; and his "Economics and policies of resource conservation" (1959).

(a) "Atmosphere", comprising such elements as air, space, weather and climate;

(b) "Hydrosphere", dealing with water;

(c) "Lithosphere", including land and soil,<sup>74</sup> and fuel and non-fuel minerals from the land and from the sea;

(d) "New energy resources", comprising such non-conventional sources as solar, geothermic, tidal and atomic energy.

29. According to modern ecologists, the activities of the biosphere<sup>75</sup> are interactive with the non-living elements of the atmosphere, lithosphere and hydrosphere in the ecosystem.<sup>76</sup> Man is able to use and transform the components of the biosphere as the need arises, but this transformation cannot go beyond the limits where the dynamic equilibrium of the biosphere would be upset.<sup>77</sup>

### 1. ATMOSPHERE

30. The atmosphere is probably the most important element in man's physical environment, since without air there can be no life. The importance of air as a natural resource has only recently been appreciated. The atmosphere is a physical mixture of about a dozen different gases (see table XI.1),<sup>78</sup> which the force of gravity

<sup>74</sup> These topics are developed only briefly in the present chapter, since they are treated extensively in chapter XII. The discussion here is merely intended to integrate the coverage of that chapter in the wider context of the present.

<sup>75</sup> The biosphere of the earth has been defined as consisting of "all life-forms and of that portion of air, land, and water in which life exists. . . . The scientific definition of biosphere . . . : a zone of the earth intersecting with the lower atmosphere, hydrosphere, and upper lithosphere". Matthews, *Man's Impact on the Global Environment* . . . (1970), p. 114. For a chronology that interrelates the evolution of atmosphere, hydrosphere, lithosphere and biosphere from the origin of the solar system, as established from evidence in geological records in rocks and in fossils, see Cloud and Gabor, "The oxygen cycle" (1970), p. 111.

<sup>76</sup> The concept of system has come to dominate analytical thinking in social science. An ecological system or ecosystem has been described as "... an open-energy system in which solar energy is incorporated into organic compounds through the photosynthetic process in green plants. Energy circulates within the plant, from plant to animal, from animal to animal, and finally through decomposing organisms, such as fungi and bacteria. In this process, the original potential energy in plants is degraded from concentrated form to greater and greater dispersion . . . until all of it is lost to the living systems. An ecosystem is somewhat analogous to an open reservoir, with energy in place of water flowing through the system. Maintaining the ecosystem requires a constant input of energy, which moves through the system and is eventually lost to the system. Through feedback mechanisms, the system maintains a certain degree of stability in what is known as a steady state . . . Populations of human beings . . . together with their total environments, form the highest level of biological integration . . . Man's societies dominate all ecosystems on earth." Ripley and Buechner, "Ecosystem science as a point of synthesis" (1967), pp. 21-22; see also Taylor, "Ecology . . ." (1959); Slobodkin, *Growth and Regulation of Animal Populations* . . . (1961), chap. 16; Watt, ed., *Systems Analysis in Ecology* (1966); Handler, *Biology and the Future of Man* (1970), chap. 11; and Murdoch, "Ecological systems" (1971).

<sup>77</sup> United Nations Educational, Scientific and Cultural Organization, *Use and Conservation* . . . (1970), p. 13. In some large areas of the globe, these limits appear to have already been attained, resulting in the disappearance of various plants and animal species, fresh water basins, soil etc. *Ibid.*, pp. 13-29.

<sup>78</sup> On the contents of the atmosphere see Magill *et al.*, *Air Pollution Handbook* (1956), p. 3-2; Mirtov, *Gaseous Composition of the Atmosphere* . . . (1964), chap. 1, particularly p. 21; Junge, (Continued on next page)

prevents from escaping into space. The sun pours energy in the form of radiation of short-wave length into this mixture. While the outermost fringe of the atmosphere is believed to be about 1,000 km above sea level, the "weather" is mainly confined to the layer of space closest to the earth, known as the "troposphere". The "stratosphere", a region of thin cloudless air extending to about 80 km lies above this, and further removed is the "ionosphere", which makes long-distance radio transmission possible.<sup>79</sup>

TABLE XI.1. AVERAGE COMPOSITION OF THE ATMOSPHERE

Gas	Symbol	Composition by volume (part per million)
Nitrogen .....	N <sub>2</sub>	780,900
Oxygen .....	O <sub>2</sub>	209,500
Argon .....	A	9,300
Carbon dioxide .....	CO <sub>2</sub>	300
Neon .....	Ne	18
Helium .....	He	5.2
Methane .....	CH <sub>4</sub>	2.2
Krypton .....	Kr	1
Nitrous oxide .....	N <sub>2</sub> O	1
Hydrogen .....	H <sub>2</sub>	0.5
Xenon .....	Xe	0.08

SOURCE: Magill et al., eds., *Air Pollution Handbook* (1956), p. 3-2.

31. Air space is an aspect of man's environment which is important not only for his productive activities but also for his health and welfare, as well as for plant and animal life. Space is also an important factor affecting the use of resources and, as a component of the biosphere, it conditions the behaviour of organic matter. The space immediately adjacent to the earth sets limits to the number of humans and other species and the inadequacy of this space can be seriously prejudicial to the well-being of both man and other living organisms.<sup>80</sup> While available information concerning the optimal relations between population and atmosphere relates mainly to subhuman life,<sup>81</sup> there have been inferences as to variation in these relations affecting humans through the medium of their organic environment.<sup>82</sup>

32. Modern industry consumes vast quantities of the atmosphere's chief chemical ingredients: nitrogen, oxygen, argon, carbon dioxide, neon, etc.<sup>83</sup> So far as nitrogen is

concerned, the reserves may be considered as virtually inexhaustible since the air over each hectare of land contains approximately 78,000 metric tons of nitrogen.<sup>84</sup>

33. The atmosphere plays the primary role in the "hydrologic cycle".<sup>85</sup> Both water supply and water power are subject to the vagaries and irregular fluctuations of the weather and climate.<sup>86</sup> Neiburger has pointed out that if and when it becomes possible to control the atmospheric circulation and, in particular, the evaporation and precipitation processes, an increase in usable water resources may be expected.<sup>87</sup>

34. Technological innovations have significantly increased man's ability to cope with unfavourable weather as well as with diseases, pests and other conditions associated with adverse climate; but the results of these innovations have not proved to be consistently predictable so far.<sup>88</sup> A number of long-term experiments have recently been undertaken in several countries for purposes of weather modification. Most of the efforts have been in the direction of dispersing fogs, increasing local precipitation and suppressing hail.<sup>89</sup> The dissipation of fogs and low stratus clouds over limited areas has become

<sup>84</sup> Lamer, *The World Fertilizer Economy* (1957), p. 99. In this connexion Delwiche states: "Of all man's recent interventions in the cycles of nature the industrial fixation of nitrogen far exceeds all the others in magnitude. Since 1950 the amount of nitrogen annually fixed for the production of fertilizer has increased approximately fivefold, until now it equals the amount that was fixed by all terrestrial ecosystems before the advent of modern agriculture. In 1968 the world's annual output of industrially fixed nitrogen amounted to about 30 million tons of nitrogen; by the year 2000, the industrial fixation of nitrogen may well exceed 100 million tons." Delwiche, "The nitrogen cycle" (1970), p. 137. See also Junge, *Air Chemistry and Radioactivity* (1963), chap. 1.

<sup>85</sup> See the discussion of the "hydrologic cycle" later in this chapter. See also Arvill, *Man and Environment* ... (1969), chap. 6, particularly the graph, p. 93; Huberty, "Fresh-water resources" (1959); and Penman, "The water cycle" (1970).

<sup>86</sup> The question as to whether the climate is really constant or changes with time has often been asked, particularly when the weather has been extreme. Flohn observed that the plotting of any continuously observable parameter of the atmosphere in terms of time would reveal short-term irregular fluctuations. Flohn, *Climate and Weather* ... (1969), p. 196. The search for regularity in the long-term climatic variations, even with the help of computers, has met with little success. Shaw gives a number of series of fluctuations that are seldom stable in time, nor do they cover large areas. Shaw, *Manual of Meteorology*, vol. 2 (1936) chap. 4-6; United Nations Educational, Scientific and Cultural Organization, *Changes of Climate* ... (1963), various papers in parts 1 and 2.

<sup>81</sup> See, for example, such studies as Christian and Davis, "Endocrines, behavior, and population ..." (1964); Watt, "The effect of population density on fecundity in insects" (1960).

<sup>82</sup> See, for example, Frank, "Ecology and demography" (1959), pp. 672-673.

<sup>83</sup> Doane, *World Balance Sheet* (1957), p. 65.

operationally practicable as has been demonstrated in clearing airport fogs in such countries as the United States, France and the Soviet Union.<sup>90</sup> There has been increasing, though somewhat controversial, statistical evidence that precipitation from cloud and storm systems can be moderately increased or redistributed by the seeding technique.<sup>91</sup> With regard to hail suppression, there is a wide range of opinion as to whether hail can be effectively suppressed or its damage mitigated. Recent experiments in the United States and in the Soviet Union have indicated that hail's damage may be cut to 75 to 80 per cent by using rapid cloud-seeding techniques.<sup>92</sup>

35. Success in modifying hurricanes and tornadoes must await the development of adequate theories of the structure and dynamics of these atmospheric storms. The type of data needed to provide information as to how hurricanes originate is as yet almost completely lacking. Recently near-earth satellites have provided photographs at an early stage of their development, but they have not been able to supply information concerning the storm's full life cycle. It is considered, however, that the new technology of computers, simulation and satellites greatly improve possibilities for fairly adequate global forecasting.<sup>93</sup>

36. Some students have warned that man's intervention in the atmosphere may involve the danger of costly mishap. They believe that attempts to tame or to reduce wind speed of hurricanes may dangerously alter the course of these erratic storms, or cause them to dump most of their rain at sea, parching the mainland. Such weather modification may also be capable of generating

a plague of destructive insects, plant diseases and noxious weeds.<sup>94</sup>

37. The modification of the atmosphere over urban areas has attracted increasing attention in recent years as a result of the accelerated trend towards urbanization. A number of urban climatic studies have suggested a persistent decrease in average wind velocity and an increase in temperature as urbanization advances. The excess of temperature in the urban areas over the surrounding areas is largely due to man-made heat sources in the former. This leads to a slightly larger precipitation probability over a city than over its surroundings. A systematic increase in the rainfall of the order of 10 per cent has been noted in a number of growing cities in the last two decades. On the other hand, precipitation in the form of snow has tended to become less frequent in the city than in the rural areas.<sup>95</sup> It has been observed that in contrast to the effects of large-scale city building, the meteorological effects of altering rural landscapes, for example, by forestation, deforestation, or irrigation, appear to be small.<sup>96</sup> Statistical evidence on climatic consequences is, in general, meagre and controversial, especially in so far as effects beyond the immediate vicinity of the limited modified area are concerned.<sup>97</sup>

38. Another important aspect of the atmosphere concerns its nature as a medium of transportation. Air transport, which is an extension or replacement of older forms of transport (water-ways, railways and highways), has increased the dynamic role of transportation in regional development.<sup>98</sup> Patterns of air transportation are affected by patterns of population distribution and levels of development. In the highly developed countries, empirical data have shown a high correlation between air passenger traffic and urban concentration of the popula-

<sup>90</sup> Schaefer and Langmuir demonstrated the efficacy of cloud seeding with dry ice and silver iodide. Schaefer, "The production of ice crystals in a cloud of supercooled water droplets" (1946); Langmuir, "Cloud seeding by means of dry ice, silver iodide, and sodium chloride" (1951), p. 41; Beckwith, "Supercooled fog dispersal for airport operations" (1965); Lessing, "Doing something about the weather . . ." (1968); and Landsberg, "Man-made climatic changes" (1970), p. 1269.

<sup>91</sup> Schaefer, "Artificially induced precipitation and its potentialities" (1956); National Academy of Sciences—National Research Council, *Weather and Climate Modification* . . . , vol. 2 (1966), pp. 124-128. For a discussion of the reasons for the controversy, see Woodley, "Rainfall enhancement by dynamic cloud modification" (1970), particularly p. 127. See also Simpson and Woodley, "Seeding cumulus in Florida: new 1970 results" (1971); Brazier-Smith, Jennings and Latham, "Accelerated rates of rainfall" (1971).

<sup>92</sup> Lessing, "Doing something about the weather . . ." (1968), p. 171. The Soviet Union experiment, which was based on direct seeding by means of rockets, is said to have been comparatively successful. Battan, "A view of cloud physics and weather modification in the Soviet Union" (1965), p. 309; and National Academy of Sciences—National Research Council, *Weather and Climate Modification* . . . , vol. 2 (1966), pp. 34-40.

<sup>93</sup> See, for example, Dobson, *Exploring the Atmosphere* (1968), chap. 5; National Academy of Sciences—National Research Council, *Natural Resources* . . . (1962), pp. 20-21; Simpson and Malkus, "An experiment in hurricane modification . . ." (1963), p. 498; National Academy of Sciences—National Research Council, *Weather and Climate Modification* . . . , vol. 2 (1966), pp. 49-54 and 134-146. Gentry describes how the wind speed of the storm was modified as a result of silver-iodide seeding of cloud. See Gentry, "Hurricane Debbie modification experiments, August 1969" (1970). See also Flohn, *Climate and Weather* . . . (1969), chap. 4; Kibel, *An Introduction to the Hydrodynamical Methods* . . . (1963); Wigger, *Meteorological Satellites* (1966); and Wick, "Nimbus weather satellites . . ." (1971).

<sup>94</sup> For example, Cry has considered what the effects on moisture climate might be in eastern and southern United States if tropical cyclones could be eliminated. See his "Effects of tropical cyclone rainfall on the distribution of precipitation . . ." (1967), chaps. 1 and 4. Sugg, "Beneficial aspects of the tropical cyclone" (1968). During the last decade, in the United States, attempts have been made to reduce wind speeds of hurricanes and typhoons by seeding clouds around the eyes of hurricanes. A 10 per cent reduction in wind speeds seems to have been achieved. See Lessing, "Doing something about the weather . . ." (1968), p. 172; see also Cooper and Jolly, *Ecological Effects of Weather Modification* . . . (1969), chap. 5.

<sup>95</sup> Landsberg, "The climate of towns" (1956) and his "Man-made climatic changes" (1970). See also National Academy of Sciences—National Research Council, *Weather and Climate Modification* . . . vol. 2 (1966), pp. 93-95; Lowry, "The climate of cities" (1967). While snowfall has generally been found to be less frequent in the cities than in the rural areas, there have been occasional reports of snowfall occurring exclusively over heavily industrialized cities, with no precipitation in the surrounding areas. Landsberg, "The climate of towns" (1956), p. 595.

<sup>96</sup> National Academy of Sciences—National Research Council, *Weather and Climate Modification* . . . vol. 1 (1966), p. 11; Sears, "The processes of environmental change by man" (1956). Pointing out that changes in the micro-climate for which man is responsible are only local, Thornthwaite stated that "man is incapable of making any significant change in the climatic pattern of the earth . . . Through changes in the water balance . . . sometimes inadvertently, he exercises his greatest influence on climate". Thornthwaite, "Modification of rural microclimates" (1956), p. 582.

<sup>97</sup> Landsberg, "Man-made climatic changes" (1970), p. 1269.

<sup>98</sup> Isard, "Transport development and building cycles" (1942); Isard and Isard, "Economic implications of aircraft" (1945).

tion. For example, a resemblance has been observed between the pattern of air transportation of the closely spaced cities of the north-east of the United States and the north-west of Europe.<sup>99</sup>

## 2. HYDROSPHERE

39. According to data provided by Colas, oceans cover three quarters of the surface of the globe and have a volume of 1,350 million cubic kilometres. In addition, there are some 30 to 50 million cubic kilometres of fresh but solid water in the polar ice caps, 300,000 to 400,000 cubic kilometres of fresh water in the world's rivers and lakes and 200,000 to 300,000 cubic kilometres in underground basins. Thus, all but 3 or 4 per cent of the earth's water consists of salt water.<sup>100</sup> Water as a renewable resource circulates on the earth in a complex series of pathways known as the "hydrologic cycle". Water is evaporated by the sun, carried as vapour and clouds in the atmosphere, and condensed by temperature changes to fall as rain, hail or snow.<sup>101</sup>

40. Water is said to be the most basic food and fundamental to life. About ten tons of drinking water per ton of living tissue are required each year by human beings and domestic animals. The *per capita* water needs of man have sometimes been graphically illustrated by a "water pyramid", containing such components as the water content of man, water contained in food and liquid-water intake, hygiene uses (washing, cleaning, and sewage), water consumed in nature or in irrigation for agricultural production, and water used in industry.<sup>102</sup> Water requirements in agriculture and industry are also high. About 1,000 tons of water are required to grow a ton of sugar or corn under irrigation. Wheat, rice and cotton require about 1,500, 4,000 and 10,000 tons of water respectively per ton of crop. Only from one to two tons of water per ton of product is needed in the manufacture of brick, but 250 tons for paper and 600 tons for

nitrate fertilizers.<sup>103</sup> For hydroelectric power<sup>104</sup> and for the rapidly expanding range of chemical products, there is an almost unquenchable thirst for more water and in some places water is becoming the limiting factor to agricultural and industrial development.<sup>105</sup>

41. Demand for water varies according to the environment. Among the factors affecting such variations are: climate (particularly rainfall distribution), location and size of the community, water reserves distribution in relation to the population, the standard of living of the population and the price of water.<sup>106</sup> In addition to the continuous increase in water demand due to population growth and other factors,<sup>107</sup> inefficiency in the use of water, water pollution etc. may create problems of water supply.

42. Data on water supply are very rudimentary for the less developed areas of the world and unreliable or incomplete for many other countries as well. For example, information on the underground water which can be extracted at economic cost is not known and a number of the rivers have not yet been measured. Despite the shortcomings of existing data, an attempt has been made to estimate approximately the world's daily water supply at different periods of time and the amounts consumed by man and by nature. As indicated in table XI.2, the world's daily water deficit appears to have increased significantly from an estimated 27,000 million gallons in 1882 to 3,664,000 million gallons in 1952; the projected deficit by 2022 was calculated at 10,723,000 million gallons. The total supply of water is shown to decline from

<sup>99</sup> In general, three factors are of significance in determining the pattern of transportation: "(a) the unequal distribution of resources; (b) the unequal distribution of population; (c) the unequal development of knowledge among men of how to utilize material resources". Sealy, *The Geography of Air Transport* (1968), pp. 21 and 138-140; see also Buchanan, "Air transport ..." (1951); Masefield, "Some economic factors in air transport operation" (1951); Taaffe, "Air transportation and United States urban distribution" (1956).

<sup>100</sup> Colas, "Le problème de l'eau" (1964), pp. 32-33. For another set of estimates see Larras, *L'aménagement des cours d'eau* (1965), p. 5. See also Gurvich, *Roĭ prirodnykh bogatstv* ... (1961).

<sup>101</sup> Through the "hydrologic cycle" which may be called nature's own desalination process, pure water vapour is absorbed by the air from the oceans at an estimated rate of 875.3 cubic kilometres (km<sup>3</sup>) a day. About 775 km<sup>3</sup> return to the ocean through condensation and precipitation, there being a net windborne transfer of some 100 km<sup>3</sup> from the seas to the land. About 260 km<sup>3</sup> daily fall upon the land, 100 km<sup>3</sup> of which are blown in from the sea, 160 km<sup>3</sup> having been previously evaporated from the land. The cycle is balanced by about 100 km<sup>3</sup> of daily run-off from land to sea via the streams, rivers and flow of groundwater. Borgstrom, *Too Many* ... (1969), pp. 132-134; see also Huberty, "Fresh-water resources" (1959), particularly pp. 30-31; Arvill, *Man and Environment* ... (1969), pp. 106-109; Penman, "The water cycle" (1970).

<sup>102</sup> Borgstrom, *Too Many* ... (1969), p. 158.

<sup>103</sup> Revelle, "Water" (1963), p. 93. See also Guerrin, *Humanité et subsistances* (1957), p. 186; Poirée and Ollier, *Irrigation* ... (1962), pp. 19-20 and chap. 4; and Cram, *Water* ... (1968), p. 45.

<sup>104</sup> Estimates of the hydropower potential of the world show that, among the continents, Africa has the largest potential. On a unit-area basis, Switzerland has the highest potential. Huberty, "Fresh-water resources" (1959), p. 49. Large hydroelectric power resources are found in mountainous regions. Thus, in the Soviet Union the greatest development in hydroelectric power is likely to occur in the eastern part of the country, and in China in the mountainous south-west. Pavlenko, "Dalneishee razvitie energetiki SSSR ..." (1958).

<sup>105</sup> Hartley, "The engineer's contribution to the conservation of natural resources" (1957), p. 21; Colas, "Le problème de l'eau" (1964). See also United Nations, *Water for Industrial Use* (1958); Bradley, "Human water needs and water use in America" (1962); Barber, "Water resource development" (1961); United Nations, *Proceedings of the United Nations Scientific Conference on the Conservation and Utilization of Resources* ..., vol. 4 (1951); and Revelle, "Water-resources research in the Federal Government" (1963).

<sup>106</sup> United Nations, *Proceedings of the Interregional Seminar on the Economic Application* ... (1967), p. 32. Findings of a study of single-dwelling residential water meter records in a United States Midwest city revealed the existence of a close relationship between *per capita* water need and such socio-economic-demographic factors as assessed valuation of the dwelling, education, occupation and family income. Dunn and Larson, "Relationship of domestic water use to assessed valuation ..." (1963), fig. 1 and table 2.

<sup>107</sup> It would be erroneous to assume that water use in a country is strictly a function of population, since water requirements of other consumer categories (i.e., household and municipal use, industry, tourism, commerce, mining and agriculture) may increase more rapidly than total population, particularly in developing areas. United Nations, *Proceedings of the Interregional Seminar on the Economic Application* ... (1967), pp. 31-32.

TABLE XI.2. THE WORLD'S DAILY WATER SUPPLY AND DEMAND, 1882, 1952, 2022  
(Thousand millions of gallons)

	1882	1952	2022 <sup>a</sup>
Average daily precipitation ...	100,558	98,191	95,835
Consumed by nature .....	99,720	97,702	95,748

SOURCE: Doane, *World Balance Sheet* (1957), p. 96. Computed from data of the United States, President's Materials Policy Commission, *Resources for Freedom* (1952).

<sup>a</sup> Projected on the basis of rates of population increase and consumption of the 1950.

100,558,000 million gallons in 1882 to a projected figure of 95,835,000 in 2022.<sup>108</sup>

43. Recent estimates for the United States show a fairly rapid withdrawal depletion of water, which is likely to continue in the future, on the basis of future trends of population and urbanization.<sup>109</sup> Withdrawal in the east is estimated to increase from 13,700 million gallons per day in 1960 to 37,400 million gallons per day by the year 2000; in the more arid west, from 59,700 to 91,700 million gallons; and in the Pacific north-west, from 11,100 to 20,200 million gallons. Net losses of water resulting from withdrawal uses are expected to nearly double by the year 2000. In Sweden *per capita* demand for water is expected to increase by 112 per cent between 1960 and 2000. According to the latest estimates, in the Soviet Union the demand for water is expected to increase in the next twenty years to between two to two and one-half times the present.<sup>110</sup> The increase in demand for

fresh water in these countries is expected to come mainly from population growth, urbanization, stepped-up industrial activity, and the boom in outdoor recreation.

44. Data on the distribution of water within continents and countries are important for assessing the adequacy of supplies, since water cannot be as easily transported from one point to another at economically acceptable costs as can farm products, metals and fuels.<sup>111</sup> For example, water resources in the Soviet Union are not well distributed in relation to that country's population. While the average supply per head is 20,000 cubic metres per annum, for the southern republics the figure is only 0.3-1.5 thousand cubic metres and for the Black Sea Basin only 1.9 thousand cubic metres.<sup>112</sup>

45. Since the stock of water on earth is fixed, efforts are continuously being made to find various devices for expanding usable supplies and ensuring their effective utilization.<sup>113</sup> For example, surface and groundwater sources can be integrated for more economic use;<sup>114</sup> demineralization of brackish water and desalination of ocean water can be accomplished by several different methods;<sup>115</sup> additional storage reservoirs can be con-

<sup>108</sup> For detailed discussion and qualifications see Doane, *World Balance Sheet* (1957), pp. 95-96. The projected figures are not to be taken as predictions. On pitfalls of hydrological forecasting, both of surface water and groundwater, see United Nations Educational, Scientific and Cultural Organization, *International Conference on the Practical and Scientific Results* ... (1970), p. 18.

<sup>109</sup> Withdrawal depletion refers to fresh water taken from streams and lakes and not returned. Landsberg, *Natural Resources for U.S. Growth* ... (1964), p. 123. Every day the population in the United States uses about 300,000 million gallons of fresh water in houses, factories or on irrigated farmland. In addition to these withdrawal uses, other large quantities are used for a variety of "flow" purposes (for hydraulic plants, in land navigation, carrying away wastes etc.) or "on-site" purposes, such as maintaining swamps for wildlife or simply providing restful and beautiful scenery for the population. Landsberg, Fischman and Fisher, *Resources in America's Future* ... (1963), pp. 258-262. Since the end of the nineteenth century when water became commonly available in urban areas via faucet, *per capita* water consumption has constantly increased. In the United States, *per capita* water consumption increased from some ten gallons per person per day on the old farms to the present average of 160 gallons. Water consumption *per capita* per day is much higher than the average in such major cities as Chicago (250 gallons) and San Diego (560 gallons). The United States consumption of water is believed to be about three times that of Western Europe. Borgstrom, *Too Many* ... (1969), pp. 158-159.

See also United Nations, *Proceedings of the Interregional Seminar on the Economic Application* ... (1967). A number of proposals for increasing water supplies, including desalination schemes, are contained in the Soviet Union's five-year plan. Voznesensky argued for the necessity of long-term

(Continued on next page)

structed;<sup>116</sup> evaporation and irrigation canal losses may be checked;<sup>117</sup> water-consuming trees and plants can be reduced; water prices can be raised to check increases in consumption;<sup>118</sup> rainfall may be induced by weather modification or other techniques.<sup>119</sup> It has also been mentioned that fertilizer can to some extent serve as a substitute for water.<sup>120</sup> While the efficient use of water can substantially reduce the quantity of water consumed both by industry and agriculture, higher efficiency often requires additional capital investment.<sup>121</sup>

46. Irrigation projects are often multipurpose in nature. For example, the Don-Volga project in the Soviet Union combines irrigation, flood control, hydropower generation and navigation. In the Kuibyshev, Stalingrad and Tsymlyansky projects, a large percentage of the capital invested is for power; that for transportation ranks second and irrigation third.<sup>122</sup> An expert group reporting to the United Nations Educational, Scientific and Cultural Organization noted that some large irrigation

<sup>117</sup> Olivier, *Irrigation and Climate* . . . (1961). It has been estimated that in Iran over 60 per cent of the annual intake of water flows into the sea or is evaporated without having done any "work". *Ibid.*, p. 4. On water evaporation, see also Poirée and Ollier, *Irrigation* . . . (1962), pp. 153-164; and Task Group Report, "Survey of methods for evaporation control" (1963). DeHaven suggested that an efficient method to protect water against evaporation is by the use of monomolecular surface films. DeHaven, "Water supply economics, technology, and policy" (1963), p. 546.

<sup>118</sup> It is generally recognized that the cost of water will ultimately lead to water's being priced and thus to its being treated as a vital natural resource. Presently, 1,000 gallons of water (purified of salt) costs a household 30 shillings in Kuwait, while only 2 shillings in Britain. In industry, the cost of 1,000 gallons of water is 12 shillings in Kuwait and as low as one shilling in many areas in Great Britain. Arvill, *Man and Environment* . . . (1969), p. 105. Illustrating the effect of price of water on demand, DeHaven noted that steel mills may require from 1,400 to 65,000 gallons of water to produce a ton of finished steel, and power plants may use from 1.32 to 172 gallons to produce a kilowatt-hour of electricity, depending on the price of water. DeHaven, "Water supply, economics, technology, and policy" (1963), pp. 540-541. Studies in the United States and Canada have found that householders became more economical in their use of water when meters were installed. In Ottawa a 100 per cent use of meters lowered daily *per capita* water consumption by 29 per cent. Studies by Langbein and Leopold and Stockwell cited in Dunn and Larson, "Relationship of domestic water use . . ." (1963), p. 442. It has been noted that increases in water price create difficulties, since prices are generally politically determined, rather than by market mechanisms. See the discussion in Hirshleifer and Milliman, "Urban water supply; a second look" (1967), p. 2 and Clark, *The Economics of Irrigation* . . . (1970), chap. 3 and 6.

<sup>119</sup> See the discussion in subsection 1 above.

<sup>120</sup> Clark, *The Economics of Irrigation* . . . (1970), pp. 18-20, and table 4.

For a discussion of the optimal level of investment in a river basin, see Boyd, "Collective facilities in water quality management" (1968).

<sup>122</sup> Huberty, "Fresh-water resources" (1959), pp. 48-49. Voznesensky and Beschinsky calculated the amounts of coal that could be saved by the substitution of hydroelectric power in the Urals. Voznesensky and Beschinsky, "Osvoenie gidroenergeticheskikh resursov sibirskikh . . ." (1957).

projects had already led to undesirable changes in the environment and warned that, until there was improved knowledge of the interaction of water and other environmental factors, the introduction of additional projects might pose a threat to the integrity of the hydrosphere and biosphere.<sup>123</sup>

47. Despite the high costs which limit the feasibility of transporting water over long distances, the development of large-scale long-distance canal and pipeline projects has proved to be a means of coping with increasing demands for water in such countries as Belgium, Israel and the Netherlands.

48. Certain arid regions of the world which do not have rivers flowing from outside areas of high precipitation must depend largely on groundwater for their source of water supply. This is practically the only source of water supply in Saudi Arabia, for example, and such dry countries as Tunisia and Morocco must also depend largely on this source. Development of groundwater resources has also proved essential in certain semi-arid regions where rainfall is erratic and streams may dry up for long periods.<sup>124</sup>

49. In water-short areas that are close to a body of brackish water or sea-water, the supply of fresh water can be increased by a number of methods, including desalination, when economically and technically feasible.<sup>125</sup> The growing requirements of water for economic development have stimulated the advance of desalination technology. Over the past decade the progress made in improving desalination processes has led to a substantial reduction in production costs. But even the most efficient of the existing methods of desalting water and pumping it to higher elevations are still too expensive to provide water for irrigation.<sup>126</sup> As regards human consumption purposes, however, some fifty water-short areas in various parts of the world have been identified recently in which technical and economic studies appear to warrant the possibilities for utilization of desalinized water. With

<sup>124</sup> United Nations, *Large-Scale Groundwater Development* (1960), pp. 2-3.

<sup>125</sup> See, for example, Koenig, "The economics of water sources" (1956), p. 321; Jenkins, "Fresh water from salt" (1957); United Nations, *Proceedings of the Interregional Seminar on the Economic Application* . . . (1967), particularly lecture Nos. 1, 12 and 18. For the "brackish" water with a salt content of up to 1 per cent, various techniques are available for desalination at a moderate cost. Sea-water, however (average salt content of 3.5 per cent), has to be distilled, and costs hitherto have been very high, far out of reach of ordinary agriculture. It has been suggested, however, that the combination of a nuclear generator and a distillation plant in an area where there was a good market for both power and water might substantially reduce costs. Clark, *The Economics of Irrigation* . . . (1970), pp. 132-133.

<sup>a</sup> Excluding Alaska.

rapidly growing population, the need for such an endeavour becomes increasingly important.<sup>127</sup>

### 3. LITHOSPHERE

50. The term "lithosphere" refers primarily to the surface of the earth which contains such substances as land, minerals, solid fuels (coal) and liquid fuels (oil and gas).

#### (a) Land

51. Land covers about one quarter of the earth's surface, but much of it is uninhabitable owing to extremes of climate or terrain (see chapter VI, section A). There are wide variations in the availability of land per head of population in the different regions and countries of the world. Among the selected countries for which data are shown in table XI.3, it is seen that Canada has about 160 acres of land *per capita*, while Japan has only about one acre.

52. As regards its use and function, land is generally classified into three broad categories: (1) that used for industry, housing, transportation and recreation; (2) that used for food and forest products; and (3) that which at present is not used for any purpose but may be drawn into use in the future.<sup>128</sup>

53. Estimates published by Doane in the 1950s showed that a little over one half of the world's land was in use—10 per cent in croplands and gardens, 20 per cent in pasture and meadow, 8 per cent in accessible forest and 15 per cent built on.<sup>129</sup> More recent estimates cited in chapter XII, section C, confirm that the area under cultivation amounts to only a little more than 10 per cent

of the world's total land area. Data for 1969 presented in table XII.10 in that chapter show that of the world's principal regions, Oceania has the largest amount of cultivated land *per capita*, amounting to more than six acres while Europe and the Far East have less than one acre. A similar wide range in arable land *per capita* is shown among selected countries in table XI.3. Whereas Canada has about 5.7 acres of arable land *per capita*, and the United States and the USSR 2.7 and 2.6 acres, respectively, Japan has only about 0.2 acres, the United Kingdom 0.4 and China 0.5 acres.<sup>130</sup>

54. While most experts agree that the amount of land under cultivation can still be expanded considerably, their estimates of potentially arable land differ by a wide margin, as shown in chapter XII, section C.<sup>131</sup> The possibility of bringing some tropical soil into use depends on the solution of the problems of cultivation of soil of lateritic and tropical types,<sup>132</sup> just as transformation of arid and semi-arid lands depends on the possibility of discovering adequate water.<sup>133</sup>

55. Large areas of the earth's habitable and cultivable land are being lost for cultivation owing to urban expan-

<sup>130</sup> See also the estimates presented by Stamp, "Conservation of land" (1957), p. 69.

<sup>131</sup> In addition to the sources cited in that chapter, see also Pearson and Harper, *The World's Hunger* (1945), p. 50; Guerrin, *Humanité et subsistances* (1957), pp. 327-333, 406; Woytinsky and Woytinsky, *World Population and Production* ... (1953), p. 323. On different classifications of agricultural land, see Zvorykin, "Study and classification of agricultural lands" (1964).

<sup>132</sup> Gerasimov, "Recent laterites and lateritic soils" (1961); Kellogg, *Food, Soil, and People* (1950), pp. 20-22; Pawley, *Possibilities of Increasing World Food Production* (1963), pp. 31-65; Tosi and Voertman, "Some environmental factors in the economic development of the tropics" (1964). It has been noted that the potentialities for supporting a larger population are much greater in the wet tropics than in either the cold or dry lands. Trewartha, Robinson and Hammond, *Elements of Geography* (1967), p. 532. For a discussion of soil as to its structure, classification, evolution, erosion and other aspects, see Jenny, "Soil as a natural resource" (1959); Demolon, *Dynamique du sol* (1952), chaps. 1, 2 and 14; Bunting, *The Geography of Soil* (1967); Guerrin, *Humanité et subsistances* (1957), pp. 132-185; and Dorst, *Before Nature Dies* (1970), pp. 128-135 and 173-174.

<sup>127</sup> United Nations, *Water Desalination in Developing Countries* (1964), chaps. 1-4 (see especially table 16).

<sup>128</sup> On classifications of land use see, for example, United Nations, *Proceedings of the United Nations Scientific Conference on the Conservation and Utilization of Resources* ..., vol. 1 (1950), pp. 71-92; Wagner, *The Human Use of the Earth* (1960); and Dorst, *Before Nature Dies* (1970), pp. 290-296.

<sup>129</sup> The estimates further showed that between 1882 and 1952, when world population increased by about 74 per cent, the acreage built on increased by 86 per cent, that in cropland about 25 per cent and that in pasture and meadow about 42 per cent. Doane, *World Balance Sheet* (1957), pp. 2, 108.

sion, mineral working, roads and erosion.<sup>134</sup> The most pressing competition for land use has resulted from accelerated urbanization.<sup>135</sup> This creates special difficulties where agricultural land is severely limited, as in Japan and the United Kingdom.<sup>136</sup> It was estimated that between 1951 and 1971 England and Wales would lose 750,000 acres of farmland to urban development, and if present trends continued the loss of farmland might be greater in the second half of the twentieth century than in the first.<sup>137</sup> In the United States it is anticipated that the acreage devoted to agriculture, commercial forestry and grazing will decline by about 69 million acres between 1950 and 2000, while that required for cities, public recreation, transportation and reservoirs will increase by about 88 million acres.<sup>138</sup> One survey estimated that the demand for land for recreation facilities would treble between 1960 and the end of the century.<sup>139</sup>

#### (b) Mineral resources

56. More than other natural resources, minerals have become associated with the industrial power and wealth of nations. Some minerals (fuels, for example) are not renewable; others used in manufacturing and construction may be reclaimed as secondary metals (scrap) and used indefinitely.<sup>140</sup> Although the amounts of non-fuel minerals are believed to be vast, many of the known deposits are of such a low grade as to be uneconomic under the present state of technology. The non-fuel minerals are contained in the solid crust of the earth, the sea and in the atmosphere.<sup>141</sup>

<sup>134</sup> Arvill, *Man and Environment* ... (1969), p. 25.

<sup>135</sup> Cities are said to extend into excellent agricultural lands. Towns built in fertile regions or along communication routes tend to spread into plains. The City Council of Moscow, for example, has made an effort to preserve an enormous forest belt around the suburbs in order to provide the flora and fauna to live in harmony with man. Dorst, *Before Nature Dies* (1970), pp. 126 and 324. See also Darling and Milton, eds., *Future Environments of North America* ... (1966), and Arvill, *Man and Environment* ... (1969), pp. 131-135.

<sup>136</sup> White, *Social and Economic Aspects of Natural Resources* ... (1962), p. 6.

<sup>137</sup> Arvill, *Man and Environment* ... (1969), pp. 57-58. See also Stamp, *The Land of Britain* ... (1950); Best and Coppock, *The Changing Use of Land in Britain* (1962); Best, "Recent changes and future prospects of land use in England and Wales" (1965).

<sup>138</sup> Clawson, Held and Stoddard, *Land for the Future* (1960), p. 442. See also Clawson, "Land resources" (1971), p. 125; Wooten and Anderson, *Major Uses of Land in the United States* ... (1957).

<sup>139</sup> Outdoor Recreation Resources Review Commission, *Outdoor Recreation for America* ... (1962), p. 32. See also Burton and Wibberley, *Outdoor Recreation in the British Countryside* ... (1965); Perloff, ed., *The Quality of the Urban Environment* ... (1969).

<sup>140</sup> Though the cost of reclaiming material is sometimes so great that recovery does not pay, with proper techniques and organization the supply of the primary mineral resources can be increased considerably. In the United States scrap is said to constitute about 50 per cent of the domestic output of iron, 60 per cent of lead, 30 per cent of copper and 12 per cent of zinc. Carlisle, "Nonfuel mineral resources" (1959), p. 320. See also United Nations Industrial Development Organization, *Utilization of Non-Ferrous Scrap Metal* ... (1970).

<sup>141</sup> For a discussion of minerals from these different sources, see, for example, Tilson, "The earth's crust" (1962); Dobson, *Exploring the Atmosphere* (1968), pp. 8-16; Riehl, *Introduction to the Atmosphere* (1965); Goldberg, "The oceans as a chemical system" (1963); Flawn, *Mineral Resources* ... (1966); Hibbard, "Mineral resources ..." (1968).

57. Since minerals are used mainly by industry rather than as consumer goods, the demand for them depends on the level of industrial activity and follows the business cycle.<sup>142</sup> A very substantial increase in the use of minerals has occurred during the present century. According to estimates of Fisher and Potter, the world increase in the production of non-fuel minerals was about 50 per cent per decade between 1937 and 1966, while world population grew at only about 16 per cent per decade. Except for tin, gold and silver, the output of every important metal and every important non-metallic mineral grew at a faster rate than did world population.<sup>143</sup> In the United States between 1900 and 1950 the population doubled, and real *per capita* income increased a little over 2 and  $\frac{1}{4}$  times; consumption of all raw materials increased about 2 and  $\frac{1}{2}$  times, agricultural products increased 2 and  $\frac{1}{4}$  times, fishery and wildlife products a little more than 2 and  $\frac{1}{4}$  times and forest products declined 1 per cent, but the amount of minerals consumed, including fuels, increased sixfold.<sup>144</sup>

58. The world's supply of mineral resources is unevenly distributed geographically, and most industrialized countries, which account for the great bulk of the world's consumption of minerals,<sup>145</sup> must rely on imports for part of their supplies.<sup>146</sup> The United Kingdom is dependent almost entirely on imports for most of the minerals required for its industry and agriculture.<sup>147</sup> Of the world's large political units, the USSR may approach closest to self-sufficiency in minerals.<sup>148</sup> The United States, once considered to be nearly self-sufficient, is completely dependent on foreign sources for tin, and for 90 per cent of all the manganese, cobalt and mercury it consumes. It was once a huge exporter of copper, lead and zinc, but it

<sup>142</sup> Carlisle, "Nonfuel mineral resources" (1959); and Pehrson, "Mineral supply" (1962).

<sup>143</sup> Fisher and Potter, "Natural resource adequacy ..." (1969), p. 119.

<sup>144</sup> The increase in consumption of individual minerals was as follows: iron ore, 4 times; lead, 4.5; manganese, 5; copper, 7; zinc, 10; chromium, 40; aluminium, 300; crude oil, 35; natural gas, 47; and coal, 2 times. Carlisle, "Nonfuel mineral resources" (1959), pp. 336-337; United States, President's Materials Policy Commission, *Resources for Freedom*, vol. 1 (1952), pp. 4-5. For a discussion of the expected increase in consumption of minerals in relation to population growth in the United States during 1965-1980, see Hibbard, "Mineral resources ..." (1968).

<sup>145</sup> According to 1960 data cited by Feiss, the value of non-fuel minerals consumed in the United States accounted for more than half of the total value of the world's production. Feiss, "Minerals" (1963), p. 129. Hubbert estimated that the industrialized areas of the world consume about 90 per cent of the world production of industrial energy and mineral resources although they have only about 30 per cent of the world's population. To bring *per capita* consumption in the developing areas to the standard of the industrialized regions would require that the former be raised by a factor of about 21. Hubbert, "Mineral resources and rates of consumption" (1967), pp. 318-319. The severe inequality between rates of mineral consumption in industrialized and developing areas has been attributed by Gurvich to the consequences of colonialism. See his *Roľ prirodnykh bogatstv* ... (1961), pp. 191-192; 196-197.

<sup>146</sup> Lovering has pointed out that all industrialized nations, with the possible exception of the Soviet Union, are net importers of most minerals and ores. See his "Mineral resources from the land" (1969), p. 120.

<sup>147</sup> Jones, "Mineral resources" (1957).

<sup>148</sup> Stamp, *Our Developing World* (1960), p. 146.

has become the largest importer of these three major mineral products.<sup>149</sup>

Zinc ore .....	28

SOURCE: Stamp, *Our Developing World* (1960), p. 179.

59. The dependence of the industrialized countries on the developing countries is evident from the geographical distribution of leading minerals. Table XI.4 shows, for selected minerals, the percentage of world production originating in developing countries, according to figures compiled by Stamp.<sup>150</sup> Thus, 95 per cent of the world's production of tin ore, 75 per cent of cobalt ore, 61 per cent of bauxite and 40 per cent or more of copper, chrome ore, manganese, and silver ore come from these areas. While new discoveries are constantly changing the situation, in the late 1950s three countries—Jamaica, Guyana and Surinam—supplied over half of the world's output of bauxite. Tin is even more localized, about 60 per cent coming from South-East Asia. The great majority of the world's cobalt is produced by Morocco, Democratic Republic of the Congo and Zambia. Iron ore is more widely distributed.<sup>151</sup> As industrialized countries use up their own cheap supplies of minerals, they are likely to have to rely more and more on foreign sources and on recycled or scrap metal.<sup>152</sup>

60. The problem of the presumably limited supply of mineral resources in the light of growing population and increasing industrialization has attracted wide attention. Table XI.5 shows the world reserves of selected minerals in terms of years of supply, according to various assumptions. It shows, in particular, that if the world's minerals were to be consumed at the rate at which the United States is using them, the known reserves of all minerals except coal would be depleted within a lifetime.<sup>153</sup> In spite of the accelerated drain on the world's mineral

resources, it is generally doubted that the supply will soon be exhausted. Such developments as new ore discoveries, resort to lower grade ores, and continued technological advance resulting in improvements in mining and processing and substitutions of more abundant materials for less abundant ones seem likely to ensure that the needs of a growing and industrializing population will be met for some time in the future.<sup>154</sup> Recent geologic, geophysical and geochemical methods of discovery and more elaborate exploration tools have helped to uncover a great number of unexpectedly rich mineral deposits.<sup>155</sup> Technology is said to keep creating new resources. Just as it is now possible to exploit ores that would have been considered worthless fifty years ago, new advances may make it possible to extract metals from still inferior ores in the future.<sup>156</sup> The critical question is said to be not merely how the world's mineral reserves will stand up under the strain of accelerating consumption and population growth, but within what probabilities and conditions can new technology continue to uncover new supplies of minerals.<sup>157</sup> While the ultimate depletion of mineral reserves is theoretically inevitable, Fisher and Potter conclude that this stage will be reached only after the world has changed

<sup>154</sup> Fisher and Potter, "The effects of population growth on resource adequacy . . ." (1971), pp. 232-233.

<sup>155</sup> Feiss points out that it will take many years to survey the world in reasonable detail. Only about two thirds of the United States has been topographically mapped and only one fifth has been mapped geologically. Feiss, "Minerals" (1963), p. 135. Stamp observed that even countries which have long had geological and mineralogical surveys have been found to have unexpected resources. Stamp, *Our Developing World* (1960), p. 144. See also Slichter, "Some aspects, mainly geophysical, of mineral exploration" (1959); Sawaf, "Minerals and living standards . . ." (1967), pp. 342-343. Also relevant are the communications assembled under the title "Increasing mineral resources by discovery," in *Proceedings of the United Nations Scientific Conference on the Conservation and Utilization of Resources . . .*, vol. 2 (1951), pp. 59-103; Tilson, "The earth's crust" (1962), and Nolan, "The inexhaustible resource of technology" (1958).

<sup>156</sup> Copper and iron ore are two examples where submarginal and low-grade deposits have become gradually economical as a result of the application of new techniques. See, for example, United States, President's Materials Policy Commission, *Resources for Freedom*, vol. 2 (1952), pp. 143-147. Table III, p. 144, shows the marked increase in the trend of copper-reserve estimates in the United States during 1931-1945 despite an annual average production of some 700,000 tons. Table VII, p. 147, indicates that while the production of iron ore increased from 36 million tons in 1908 to an annual average of more than 100 million tons during the decade of 1940-1950, the available reserves increased from 4,800 million long tons in 1908 to 6,400 million long tons in 1950. A recent survey by the United Nations on the total iron ore resources of the world (reserves plus potential ore) has revealed that they have increased from 174,190 million tons in 1954 to 782,500 million tons in 1967. United Nations, *Survey of World Iron Ore Resources . . .* (1970), p. 8.

<sup>157</sup> Nolan, reviewing the development of science and technology in the first half of this century, states that "... it does not seem too improbable that, through one or another of the methods of improved exploration techniques, exploitation of presently unavailable supplies, or programs of substitution and improved utilization, raw materials for our civilization can be obtained for a long period in the future . . ." Nolan, "The outlook for the future . . ." (1955), p. 7. Barnett and Morse, *Scarcity and Growth . . .* (1963). For a discussion of future technology and its implication for minerals, see Landsberg, Fischman and Fisher, *Resources in America's Future . . .* (1963), pp. 488-496. These authors have also discussed the possibility of the occurrence of rich deposits of minerals on the moon and neighbouring planets of the solar system.

<sup>a</sup> Unadjusted for population trends.

<sup>b</sup> Basis for estimate not available.

61. The chemical industry, which produces vast varieties of solvents, medicines, fertilizers, dyes, bleaching agents, plastics and the like, is said to be as important to industrialized society as the metal industry.<sup>159</sup> The important role of this industry in affecting the supply of resources is seen in the widespread use in recent years of polymeric materials, or plastics, as substitutes for such products as natural rubber, wood, glass, natural fibers, copper, lead, zinc, aluminium and even iron.<sup>160</sup> This industry also plays a prominent role in food production, since modern agriculture relies on chemistry for soil nutrients and the control of insects. Chemical agents can

<sup>158</sup> Fisher and Potter, "The effects of population growth on resource adequacy ..." (1971), p. 233.

<sup>159</sup> Stevenson has noted that chemical products "have a role in satisfying the six basic needs of mankind—food, clothing, shelter, transportation and communication, medication, and tools, machinery and equipment with which to work". Stevenson, "Past gains and future promise" (1959), p. 115.

<sup>160</sup> Brown, *The Challenge of Man's Future* ... (1954), pp. 207-210. On contributions of the chemistry industry, see also Borgstrom, *Too Many* ... (1969), chap. 2. A basic shift in the pattern of metal use since the Second World War has seen greater competition for steel production from aluminium, magnesium, titanium, structural concrete and a variety of strong solid plastics. Feiss, "Minerals" (1963), p. 129; and Brown, "Human materials production as a process in the biosphere" (1970), p. 200. On possible replacements for steel products see also United Nations, Economic Commission for Europe, *Competition between Steel and Aluminium* (1954); *Steel and its Alternatives* (1956); *Aspects of Competition between Steel and other Materials* (1966). See also Zackay, "The strength of steel" (1963).

raise crop yields even on poor soil, and chemical technology is able to transform low-value agricultural products into new resources.<sup>161</sup>

62. The sea contains a large variety of minerals<sup>162</sup> in the form of dissolved substances at low concentration, but at present only magnesium, bromine and common salt are being extracted in significant quantities. As shown in table XI.6, in 1964 about 90 per cent of the magnesium and 45 per cent of the bromine produced in the United States came from sea-water. Extraction from the sea of such elements as sodium, sulphur, potassium, and iodine also seems feasible in the future, though it is improbable for such elements as silver, gold, platinum, tin, molybdenum, nickel, tungsten, mercury and many others.<sup>163</sup>

63. Table XI.6 shows that for the world as a whole mineral products obtained from the sea represented about 10 per cent of the total value of all mineral production. In addition to the minerals from sea-water already mentioned, substantial quantities of oil, gas and sulphur, from beneath the sea floor, and sand and gravel from the sea floor were also extracted.<sup>164</sup> Weeks has estimated that 700,000 million barrels of petroleum liquids can be produced by primary recovery methods from beneath the continental shelves of the world.<sup>165</sup> The floor of the deep sea contains low-grade deposits of cobalt, nickel, and copper associated with deposits of iron and manganese, but the technological problems of mining these materials, in view of the great depth and pressure, have not been solved.<sup>166</sup>

<sup>161</sup> Herber, *Our Synthetic Environment* (1962), p. 39. Moore has commented that the raw materials required by the chemical industry: coal, limestone, corn cobs, oat hulls, and other agricultural by-products are of low value, plentiful, and in some cases waste products. "Chemical technology thus forces us to revise our estimate of what constitutes the resource base of our economy." Moore, "Unlocking new resources" (1959), p. 137.

<sup>162</sup> Among many works on the mineral resources of the sea are the following: Borgese, "The republic of the deep seas ..." (1968); Stephens, "Ocean harvest" (1967); Mero, *The Mineral Resources of the Sea* (1964); Emery, "Geological methods for locating mineral deposits on the ocean floor" (1966); Wenk, "The physical resources of the ocean" (1969); United Nations, *Mineral Resources of the Sea* (1970).

<sup>163</sup> Cloud, "Mineral resources from the sea" (1969), pp. 137, 140-141 and table 7.2; see also Wenk, "The physical resources of the ocean" (1969), p. 171.

<sup>164</sup> Emery noted that it could safely be predicted that the production of petroleum and natural gas from the world's continental shelves would increase at a faster rate than that from wells drilled on land. With continued urbanization, and a preference for coastal regions, off-shore production of sand and gravel, which are used for construction purposes, are also likely to expand greatly. Emery, "The continental shelves" (1969), p. 121; see also Schaefer and Revelle, "Marine resources" (1959), pp. 87-90; and Wenk, "The physical resources of the ocean" (1969).

<sup>165</sup> Weeks, "World offshore petroleum resources" (1965), p. 1680; and his "Offshore oil ..." (1965), p. 133. See also Hubbert, "Energy resources" (1969), pp. 194-196.

<sup>166</sup> Schaefer and Revelle, "Marine resources" (1959), p. 89. On improvements in technology, see Bascom, "Technology and the ocean" (1969), p. 199; United States, *Marine Science Affairs* ... (1969); Wang, "Latest advances in off-shore petroleum technology" (1971). See also Tilson, "The ocean" (1966), particularly the table on page 27; National Academy of Sciences-National Research Council, Committee on Oceanography, *Economic Benefits from Oceanographic Research* (1964), p. 17; Mero, "Minerals on the ocean floor" (1960); and his *The Mineral Resources of the Sea* (1964), pp. 127-241; Vine, "Spreading of the ocean floor ..." (1966).

64. It has been noted that the expected sharp rise in demand for resources associated with population growth and rising gross national product is likely to imply a greater role for the sea in meeting demand. Wenks has pointed out that by the end of the century one-half of the population of the United States may be settled in three coastal urban belts comprising the megalopolises of the Atlantic, the Pacific and the Great Lakes, thus causing an intensification of competing demands on the resources of the narrow coastal zones.<sup>167</sup> A long-run factor threatening the coastal areas is the rising sea level from melting ice caps or movements of the land which may result in the submersion of some resources now above sea level.<sup>168</sup>

### (c) Energy resources

65. It is universally recognized that the energy<sup>169</sup> that sustains all living systems is derived from solar radiation. The total amount of solar energy fixed on the earth places a limit on the total amount of life; the patterns of flow of this energy through the earth's ecosystems set additional limits on the kinds of life on earth.<sup>170</sup> The solar radiation, which is absorbed by the leaves of plants and stored as chemical energy, furnishes the essential energy source for the human population and entire animal

kingdom. The present supply of fossil fuels—coal, petroleum and natural gas—originated from the organic matter of former plants and animals which had become buried in sedimentary sand, muds and limes in a state of incomplete oxidation.<sup>171</sup>

66. The use of energy is a key to the supply of food, to physical comfort, and to the enhancement of the quality of life beyond the essentials necessary for survival. It can be said that, with time, man's use of the energy supply has reached the stage of a steadily growing availability of additional energy sources. In the course of these developments, and partly as a consequence, human population growth was accelerated, but the acceleration in the expansion of available energy supplies has been even greater. The greater utilization of energy depends on energy resources already tapped, technological skills, and the social organization by which technology and its utilization are supported and being promoted. In earlier times, the amount of energy used generally progressed at little more speed than the size of human population. But with the discovery of coal, about eight centuries ago, and the

<sup>168</sup> Cloud, "Mineral resources from the sea" (1969), p. 152.

<sup>169</sup> On the role of energy in the universe, see, for example, Dyson, "Energy in the universe" (1971); Ubbelohde, *Man and Energy* ... (1963); and Dicke, *Gravitation and the Universe* (1970).

<sup>170</sup> See, for example, Sagan, "On the origin and planetary distribution of life" (1966); Woodwell, "The energy cycle of the biosphere" (1970).

<sup>171</sup> Hubbert, "Energy resources" (1969), p. 157. The flow of energy through the earth's surface environment comes principally from three main sources: (a) the intercepted solar radiation; (b) thermal energy, which is conveyed to the surface of the earth from the warmer interior by the conduction of heat; and (c) tidal energy, derived from the combined kinetic and potential energy of the earth-moon-sun system, manifested principally in the oceanic tides and tidal currents. Of the total energy influx into the earth's surface environment, solar radiation accounts for 99.98 per cent. Hubbert, "The energy resources of the earth" (1971), p. 62; see also Jeffreys, *The Earth* ... (1970); Went, "Photosynthesis" (1959); Putnam, *Energy in the Future* (1953), pp. 198-204; Oort, "The energy cycle of the earth" (1970); Murdoch, ed., *Environment* ... (1971); and Gough and Eastlund, "The prospects of fusion power" (1971).

TABLE XI.7. PATTERNS OF WORLD CONSUMPTION OF ENERGY, 1950 AND 1969

Type of energy	1950		1969		Average annual rate of increase, 1950-1969 (percentage)
	Million metric tons of coal equivalent	Percentage distribution	Million metric tons of coal equivalent	Percentage distribution

SOURCE: 1950 data from United Nations, *World Energy Supplies, 1956-1959* (1961), table 1; 1969 data from ———, *1966-1969* (1971), table 1.

discovery of petroleum just over one century ago, the rate of energy use began to outpace population growth to an increasing extent.<sup>172</sup>

67. Prior to the seventeenth century man's productivity depended mainly on his own labour and that of domestic animals. After 1700 power and machinery came increasingly into use and began to affect productivity significantly. The impact of these developments is illustrated by the case of agriculture in the United States, where productivity more than doubled between 1920 and 1960, at a time when machines and tractors were rapidly replacing animals on farms.<sup>173</sup>

68. There has been a significant change in the pattern of demand for energy in the last century and particularly in recent decades. Table XI.7 shows a marked trend away from coal and other solid fuels towards the use of liquid fuels and natural gas between 1950 and 1969. In 1950, 62 per cent of the world's energy requirements were provided by solid fuels, and 25 per cent by liquid fuels; by 1969, however, the share of solid fuels dropped to 37 per cent while that of liquid fuels rose to 41 per cent. The most significant change was that of natural gas whose share almost doubled from 1950 to 1969 (from 10.9 to 20.3 per cent). During 1950-1969, consumption of natural gas grew at an annual rate of 7.8 per cent, liquid fuels at 7.0 per cent and solid fuels at only 2.0 per cent.<sup>174</sup>

<sup>172</sup> Hubbert, "Energy resources" (1969), pp. 157-160. Commenting on the importance of energy reserves, Brown states: "If our energy resources dwindle, our industrial technology will dwindle, and life expectancy and population will slowly dwindle with it". Brown, *The Challenge of Man's Future* ... (1954), p. 167.

<sup>173</sup> Other factors such as the introduction of new hybrid grains, the use of fertilizer and pesticides, and irrigation also contributed to rising productivity. Starr, "Energy and power" (1971), pp. 38-41. In 1918, one fourth of United States harvested crop acreage was used to produce food for the nation's more than 25 million horses and mules. Many more animals and men to work them would be required to produce current agricultural output if methods had remained unchanged. An animal-powered agriculture on an essentially fixed land base could not have supported the American economy of the 1960s. Pinches, "Revolution in agriculture" (1961), pp. 4-5.

<sup>174</sup> United Nations, *World Energy Supplies, 1956-1959* (1961) and ———, *1966-1969* (1971), table 1. See also Schurr, "Energy" (1963), especially the graph on page 114; Starr, "Energy and power" (1971), especially the graph on page 39. Landsberg's historical study for the United States found a great swing from muscle-power to fuels and hydroelectricity. In 1850, only one third of the energy used in the American economy was of inanimate

69. Landsberg has pointed out that there has been a strong interaction between the form in which energy is demanded and the supply of different fuels. Oil output rose, for example, when its use for firing boilers and driving machines was discovered. It expanded even more when demand developed for a liquid fuel to power internal combustion engines.<sup>175</sup>

70. A country's energy consumption has been shown to be closely related to its national production.<sup>176</sup> In an analysis of data for 47 countries, Schurr found a strong positive correlation between *per capita* consumption of energy and the *per capita* gross national product.<sup>177</sup> There are, of course, limits to the extent to which increas-

origin, one half came from draft animals and about one eighth from human beings. By 1950, however, human and animal energy combined accounted for only about 1.5 per cent of all energy consumed. Fuelwood was dominant until around the turn of the century when coal took over only to be later surpassed by both oil and gas. In view of these great changes, Landsberg noted that there was small reason to believe that the present pattern would endure. Landsberg, "History and prospects" (1968), pp. 28-29.

<sup>175</sup> Landsberg, "History and prospects" (1968), p. 29; see also United States, President's Materials Policy Commission, *Resources for Freedom*, vol. 3 (1952), chap. 1.

<sup>176</sup> It has been said that energy consumption is conceptually similar to national product in that each is identified with the work performed, which in one case is expressed in units of energy and in the other in units of currency. In so far as international comparisons are concerned, units of energy have an advantage over units of currency, since the former have precise and unchanging mathematical relativity to each other. Zagoroff, "National income and general productivity in terms of energy" (1955), p. 101.

<sup>177</sup> Schurr, "Energy" (1963). See also United Nations, *Changing Patterns in the World Energy Situation* ... (1971), p. 5. Empirical investigations of the relationship between energy consumption and national production were first undertaken in the late 1940s by such authors as Dewhurst and Hartley. Dewhurst, "Relation of energy output to production ..." (1948); Hartley, "Limiting factors in world development ..." (1949), pp. 50-51. The relationship was further studied by Barnett, who advanced the notion of effective use of energy. Barnett, *Energy Uses and Supplies* ... (1950). Robinson and Daniel, as well as Mason, found high correlations between *per capita* consumption of energy and *per capita* product in the 1950s. Robinson and Daniel, "The world's need for a new source of energy" (1956), particularly figures 2 and 3; and Mason, "Energy requirements and economic growth" (1956). See also Prévôt, "Les variations concomitantes de l'énergie consommée et du produit national" (1951); Schurr *et al.*, *Energy in the American Economy, 1850-1975* ... (1960), pp. 13-17; Cottrell, *Energy and Society* ... (1955); Kindleberger, *Economic Development* (1965), p. 70, particularly graph 4.4; and Starr, "Energy and power" (1971).

ing use of energy can raise production and output *per capita*.<sup>178</sup>

SOURCE: compiled from United Nations, *Changing Patterns in the World Energy Situation* ... (1971), table 2.

<sup>a</sup> Includes North America, Western Europe, Japan, South Africa and Oceania.

<sup>b</sup> Includes Eastern European countries, the USSR, China, Mongolia, North Korea and North Viet-Nam.

<sup>c</sup> Estimate for China and North Korea only. It should be noted that 1950 was an abnormal year for China and a more appropriate base year might be the first year of the first Five-Year Plan, namely, 1953-1957.

<sup>d</sup> Developing countries comprise countries in the Americas, excluding North America; countries in Africa, excluding South Africa; and countries in Asia, excluding Japan and the centrally planned economies of Asia, listed in foot-note <sup>b</sup> above.

71. Table XI.8 indicates that the world consumption of energy, which amounted to more than 6,000 million tons of coal equivalent in 1968, increased by 5.0 per cent per annum between 1950 and 1968. Urbanization and industrialization have been the major underlying factors for this growth. However, the rate of growth of world energy consumption diminished slightly, from 5.3 per cent in the decade of the 1950s to 4.5 per cent in the decade of the 1960s, partly due to a shift from less efficient to more efficient fuels, that is, from solid fuels to liquid and gaseous fuels.<sup>179</sup> The pattern of energy consumption varied among different groups of countries. In the developed market economies, total energy consumption

<sup>178</sup> Putnam, *Energy in the Future* (1953), pp. 449-453; DuBoff, "A note on the substitution of inanimate for animal power" (1964). On the decline of output per installed horsepower as horsepower increases relative to population, see Renshaw, "The substitution of inanimate energy for animal power" (1963).

doubled between 1950 and 1968, as the average rate of growth was 4.0 per cent per annum. In the centrally planned economies of the European continent the growth rate of energy consumption was relatively high, averaging 6.2 per cent during 1950-1968. In the developing countries there was also a high rate of growth in energy consumption—7.5 per cent per annum. The table also shows that, despite the more rapid rate of population growth in the developing countries, their average annual *per capita* growth rate of energy consumption—4.8 per cent—equalled that of the centrally planned economies of Europe and surpassed that of the developed market economies—2.8 per cent. While *per capita* energy consumption was rising comparatively fast in the developing countries, the level remained very low in comparison with the more developed parts of the world. In 1968 *per capita* energy consumption was estimated at only 299 kilogrammes of coal equivalent in the developing countries, compared to 3,850 kilogrammes for the European centrally planned economies and 5,436 kilogrammes for the developed market economies.<sup>180</sup> The low average energy consumption figures for the developing countries conceal further disparities between the urban centres and the more

<sup>180</sup> The data on energy consumption are somewhat understated since they do not include non-commercial energy sources (e.g. wood, animal power), information on which is not readily available. This omission creates a bias in comparisons of developing and more developed countries, since non-commercial forms of energy account for a much larger proportion of energy supply in the former than in the latter. See United Nations, *Changing Patterns in the World Energy Situation* ... (1971), p. 3.

TABLE XI.10. ACTUAL ENERGY CONSUMPTION IN 1960 AND PROJECTED ENERGY CONSUMPTION IN 2000 BASED ON VARYING ASSUMPTIONS: MAJOR REGIONS OF THE WORLD

<sup>a</sup> 1950-1960 trend roughly estimated.

backward rural areas where a large population lives often without an electricity supply and at a subsistence level.<sup>181</sup> A further indication of the wide variations that exist throughout the world in *per capita* energy consumption, and hence in levels of living, is given in table XI.9, which shows estimates of *per capita* energy consumption in selected countries of the world in 1969.

72. Energy consumption also shows marked differences in structure from one country to another. In the Soviet Union, about three quarters of total energy consumption was derived from coal around 1960, while the comparable figure for the United States was about one third. On the other hand, petroleum accounted for about 10 per cent of energy consumption in the Soviet Union, but 20 per cent in the United States. The corresponding figures for natural gas consumption were 6 per cent and 46 per cent respectively in the two countries.<sup>182</sup>

73. Projections of future world energy consumption have been made by various authors.<sup>183</sup> According to Milton Searl's projections, cited by Schurr, energy consumption in the year 2000 would be about five times that of 1960 while, during the same period, world population would only have doubled. These projections show that at the end of the century North America, Western Europe and Oceania may account for about 45 per cent of the world's total energy consumption, compared with about 60 per cent in 1960. The less developed regions are likely to increase their share of world energy consumption

from about 20 per cent in 1960 to about 35 per cent in the year 2000. One factor in the rise in energy consumption in these regions is their rapid rate of population growth, as a result of which they are expected to increase their share of world population. The main factor in the increased proportion of world energy consumption in these areas, however, is the assumption of advances in their industrialization and economic development. The remainder of the world's energy consumption—about one fifth of the total both in 1960 and 2000—is accounted for by the Soviet Union and Eastern Europe.<sup>184</sup>

74. Fisher and Potter have projected energy consumption to the year 2000 on the basis of four sets of assumptions as shown in table XI.10. The results of three of these projections (that is, all except the one based on the 1960 United States level of energy consumption which is probably unattainable) appear fairly consistent with the results presented by Schurr, since they indicate that the world energy consumption in the year 2000 will be within a range of 4 to 6 times that of 1960.

75. Brown and his associates estimated that nuclear energy may account for about one-third of total energy

<sup>181</sup> United Nations, *New Sources of Energy and Energy Development* ... (1962), p. 5.

<sup>182</sup> Campbell, *The Economics of Soviet Oil and Gas* (1968), p. 180.

<sup>183</sup> See, for example, Landsberg, Fischman and Fisher, *Resources in America's Future* ... (1963); Fisher and Potter, *World Prospects for Natural Resources* ... (1964); Schurr, "Energy" (1963).

<sup>184</sup> Schurr, "Energy" (1963), p. 112. Past experience of the United States in energy consumption supports these assumptions. During 1850-1910, a period of rapid industrial growth in the United States, the average annual rate of growth of *per capita* energy consumption was about 5 per cent, whereas in subsequent decades the rate fell substantially. Schurr *et al.*, *Energy in the American Economy, 1850-1975* ... (1960), p. 521. Putnam argues that, as a result of acquiring modern technology and benefiting from technical assistance programmes, the future rates of growth in *per capita* energy demand in the developing countries may even exceed the fastest rate yet recorded. Putnam, *Energy in the Future* (1953), p. 114. Scarlott places emphasis on the population's "growing taste for the things energy can do". Scarlott, "Fossil fuels—reserves, use, and prospects" (1959), p. 413.

consumption by the end of the century, and by the middle of the next century would supply most of the world's energy needs. They foresaw a slow continuous increase in the consumption of coal and a levelling off of the consumption of petroleum in the last quarter of the present century, followed by a decline.<sup>185</sup>

76. Estimates of potential energy resources are subject to many uncertainties. None the less, Hubbert has estimated the ultimate potential reserves of the various classes of the fossil fuels in terms of their energy contents. According to him, "The total ultimate energy for all the fossil fuels is approximately  $27.4 \times 10^{15}$  kilowatt-hours of heat. Of this 71.6 per cent is represented by coal, 17.3 per cent by petroleum and natural gas, and 11.1 per cent by tar sands and oil shale. The fraction consumed already is 4.1 per cent for coal, 10 per cent for petroleum and natural gas, and zero for tar sands and oil shales".<sup>186</sup>

77. Examinations of energy consumption, in retrospect, indicate that there has been a steady improvement in the efficiency with which energy is converted to heat, light and work. According to Summers, in the United States between 1900 and 1970 the efficiency with which fuels were consumed increased roughly by a factor of four. In recent years, however, gains in fuel economy have become more difficult to achieve, and increases in fuel consumption have risen faster than the gross national product. Since nuclear power plants convert only about 30 per cent of the energy in the fuel into electricity, whereas the comparable figure for the best fossil-fuel plants is about 40 per cent, it is clear that the expected increase in the use of nuclear fuels in the next decades may lead to a lower efficiency.<sup>187</sup>

#### 4. NEW SOURCES OF ENERGY

78. Because of the increasing consumption of fossil fuels, if man and his institutions are to survive in the long run, other sources of energy will have to be explored for possible replacement. One of these new sources is solar energy.

79. According to Daniels, the total solar energy reaching the earth is much greater than the total energy requirements of the world's population and technologically could be used to replace present energy sources, such as fuels and electricity.<sup>188</sup> The world's consumption of

fuels amounts to the equivalent of 25,000 kilocalories daily *per capita*, while food consumption is the equivalent of only 2,500 kilocalories. Thus ten times as much energy is required for man's tools and machines as for his nourishment. In the United States, where the ratio of fuel energy to food energy is much higher—50 to 1—150,000 kilocalories of heat per person per day is used to heat houses, to operate automobiles, trains and tractors, to carry out manufacturing operations and mechanical work.<sup>189</sup>

80. Two channels of the flux of solar energy are now known as large-scale sources of energy for human utilization. The first is the mechanism of photosynthesis for the entire biological system;<sup>190</sup> the second is the heat-engine channel, which produces principally the atmospheric and oceanic circulations and the hydrologic cycle, leading to wind power and water power.<sup>191</sup> Daniels listed a number of non-biological uses of solar energy including water and building heating, cooling and refrigeration, water distillation, solar furnaces, solar cookery and numerous thermoelectric, photoelectric and other means of electrical conversion or storage of solar energy.<sup>192</sup> Most of these uses are, however, still in the experimental stage. While it is possible to trap much of the solar energy and to convert it into heat inside a building fitted with suitable windows that let the sunshine in but do not let heat escape, house heating with solar energy is not yet generally economically feasible.<sup>193</sup> Solar water heating is the widest current application yet established on a commercial basis. In Japan, annual sales are as high as 100,000 units, ranging in price from about \$6 up to much higher prices for more durable and complex units.<sup>194</sup>

than the world's present installed electric power capacity. Hubbert, "Energy resources" (1969), p. 206. It is 5,000 times the energy input from all other sources combined. Hubbert, "The energy resources of the earth" (1971), p. 62.

<sup>189</sup> Daniels, "Introduction" (1955), p. 3; see also his *Direct Use of the Sun's Energy* (1964), chaps. 3-9.

<sup>190</sup> See the discussion in the preceding subsection. See also, for example, Rabinowitch and Govindjee, *Photosynthesis* (1969); Olson, "The evolution of photosynthesis" (1970); and Hutchinson, "The Biosphere" (1970), p. 47, and chart on pp. 50-51.

<sup>191</sup> See, for example, Stewart, "The atmosphere and the ocean" (1969); Lorenz, *The Nature and Theory of the General Circulation . . .* (1967); Palmén and Newton, *Atmospheric Circulation Systems . . .* (1969); and Perman, "The water cycle" (1970).

<sup>192</sup> Daniels, *Direct Use of the Sun's Energy* (1964), chaps. 5-18, each dealing with one topic in detail. See also various communications in Daniels and Duffie, eds., *Solar Energy Research* (1955); and Jukes, "Nuclear energy and other recent developments . . ." (1967), p. 327.

<sup>193</sup> Daniels and Duffie, eds., *Solar Energy Research* (1955), section 3, particularly p. 31.

<sup>194</sup> Tanishita, "Recent development of solar water heaters in Japan" (1964). See also Oshida, "Use of solar energy for heating purposes . . ." (1964). The widespread interest in solar energy utilization is reflected in papers on solar energy submitted to the United Nations Conference on New Sources of Energy, which was held at Rome in 1961. Among topics of discussion were: water heating, space heating, heat storage, solar drying, solar cooking, solar refrigeration for food preservation, solar air conditioning, solar distillation producing fresh water, solar furnaces, etc. See United Nations, *New Sources of Energy and Energy Development . . .* (1962), particularly p. 33. See also United Nations, *New Sources of Energy and Economic Development . . .* (1957), particularly chap. 4.

<sup>185</sup> The authors assume that: "Barring a world catastrophe, and assuming that industrialization will spread throughout the world, that population will continue to grow, and that we shall have adequate brainpower to solve our prodigious technical problems as they arise, total energy consumption will continue to rise rapidly, following the law of compound interest." Brown, Bonner and Weir, *The Next Hundred Years . . .* (1957), pp. 108-110. See also Brown, "The next ninety years" (1967).

<sup>186</sup> Hubbert, *Energy Resources . . .* (1962), p. 88. A considerable number of estimates are available for potential reserves of petroleum, coal and other fossil fuels. See Ayres and Scarlott, *Energy Sources—The Wealth of the World* (1952), chaps. 3-5; and Scarlott, "Fossil fuels—reserves, use and prospects" (1959). See also Hubbert, "Energy Resources" (1969), tables 8.2 and 8.6 and fig. 8.24, and his "The energy resources of the earth" (1971).

<sup>187</sup> Summers, "The conversion of energy" (1971), p. 149.

<sup>188</sup> Daniels, *Direct Use of the Sun's Energy* (1964), p. 351. Hubbert has pointed out that the thermal power intercepted by the earth's diametral plane ( $17.7 \times 10^{15}$  watts) is about 100,000 times larger

81. The possibilities for applying solar energy appear to be particularly promising in the developing regions. In the first place, many of these areas have insufficient supplies of conventional energy sources, and secondly, they are for the most part situated in a favourable geographical location, since solar energy is most readily accessible between latitudes 40° north and 40° south. In the more developed countries the question often arises of the economic feasibility of solar energy and its competition with the present energy sources based on fuels; it is foreseen that solar energy in these regions is likely to be mainly applied for such purposes as solar furnaces for research, solar power in space vehicles and water heating.<sup>195</sup>

82. The low intensity of radiant energy in sunlight calls for more efficient devices for its harnessing.<sup>196</sup> Recent models for a solar energy system have attracted considerable attention. Meinels has designed a system to capture the sun's energy by means of specially coated collecting surfaces, which would be heated by the resulting "greenhouse" effect to a temperature as high as 540° C;<sup>197</sup> Glaser, on the basis of current developments in space exploration and photo electric conversion, proposed placing a lightweight panel of solar cells in an orbit 22,300 miles above the equator, where they would be exposed to sunlight 24 hours a day. Solar cells would convert the radiant solar energy into electric power which would be converted into microwave radiation and beamed to the earth.<sup>198</sup>

83. Wind energy is considered to be unlikely to increase the energy supply substantially. A disadvantage is that wind power is variable over time and can therefore not guarantee a steady electric output. Wind power had been widely used in the past for such operations as pumping water in agricultural areas, but the expansion of rural electrification systems in developed countries led to its abandonment. However, there are still many cases in developing countries where simple wind-driven pumps and grain-mills may be both feasible and economic.<sup>199</sup>

84. The development of water power is generally expected to continue despite possible high costs involved, which result from the fact that in most developed countries the best and most economic sites have already been utilized. Moreover, since hydropower is a non-polluting

means of producing energy, its future use is likely to increase considerably. In developing countries there are still some potentially cheap hydropower sites remaining. Table XI.11 shows that the potential water power of the world is estimated at 2,857,000 megawatts. The continents of Africa and South America, both deficient in coal, appear to have the highest potential water-power capacities—780,000 megawatts for Africa and 577,000 megawatts for South America.

SOURCE: Hubbert, "Energy resources" (1969), p. 209.

<sup>a</sup> Estimated around 1960.

85. By 1966, the installed water-power capacity of the world amounted to about 230,000 megawatts, which is only about 8 per cent of its potential capacity. Since in 1966 the total installed electric-power capacity of the world amounted to about 840,000 megawatts, the total potential hydropower capacity of the world was thus more than three times as large as the total installed electric-power capacity.<sup>200</sup>

86. Tidal power is said to be similar to hydroelectric power in all essential respects except that it is obtained from the flow of water in filling and emptying coastal basins caused by the rise and fall of ocean tides. Although small tidal mills were used for the grinding of grain as early as the twelfth century, tidal-electric installations have been brought into operation only recently. The first major tidal-electric plant was installed at La Rance, France, in 1966. Of the actual and potential major tidal power sites in the world, nine are in North America (Bay of Fundy), eight in France, four in the Soviet Union, one in Argentina, and one in the United Kingdom. The total maximum rate of energy dissipation for all these localities amounts to about 64,000 megawatts, of which perhaps 20 per cent, or 13,000 megawatts, might represent actual power recoverable, according to Hubbert.

<sup>195</sup> United Nations, *New Sources of Energy and Energy Development* ... (1962), p. 8.

<sup>196</sup> *Ibid.* Ubbelohde points out that in order to obtain very high temperature from sunlight, some form of focusing lens or reflector has to be constructed to concentrate the energy collected over a large area into a very small region of space. Ubbelohde, *Man and Energy* ... (1963), p. 67.

<sup>197</sup> Hammond, "Solar energy ..." (1971).

<sup>198</sup> Glaser's model is described in Summers, "The conversion of energy" (1971), pp. 158-159.

<sup>199</sup> See various communications submitted to the 1961 United Nations Conference on New Sources of Energy in United Nations, *New Sources of Energy and Energy Development* ... (1962), pp. 28-32; and Brooks, "Solar, wind, and water-power resources" (1959), particularly pp. 444-445. One scheme which is believed to offer promise is "... to use the variable power output of a wind generator to decompose water into hydrogen and oxygen. These would be stored under pressure and recombined in a fuel cell to generate electricity on a steady basis." Summers, "The conversion of energy" (1971), p. 157.

<sup>200</sup> United States, Federal Power Commission, *World Power Data* ... (1969), table 7. Hubbert cautioned against concluding from such figures that full development of the world's potential water-power capacity would make it possible for the world to continue, without the present supply of fossil fuels, at an industrial level comparable to the present on water power alone. He noted two conditions, which offset such an expectation. First, the sacrifice of natural scenery which the full development of water power would entail and, second, the fact that reservoirs formed by dammed streams are continuously receiving deposits of sediments which may cause them to become completely filled after a century or two. Hubbert, "Energy resources" (1969), p. 209.

Compared to the estimated potential water power of the world (2,857,000 megawatts as shown in table XI.11) potential tidal power amounts to less than 1 per cent. Tidal power has certain advantages, however, in that it can be developed in very large units in certain favourable localities; it creates no noxious wastes, does not consume exhaustible energy resources and does not seriously disturb the ecologic and scenic environment.<sup>201</sup>

87. One of the energy inputs into the earth's environment consists of the heat conducted from the earth's interior as a result of the increase of temperature with depth; another consists of the heat convected to the surface by volcanoes and hot springs. Recent explorations have revealed that reservoirs of steam and hot water are widespread in the earth's crust. It is also possible that geothermal fields may be found under the seas.<sup>202</sup> Geothermal electricity production began early in the twentieth century when a turbine with the capacity of a few hundred watts was installed at Larderello in Italy. By 1960 the total output of the Larderello plants exceeded 300,000 kilowatts and geothermal power plants had also been established in a few other countries. Altogether their combined capacity (including Larderello) was about 390,000 kilowatts.<sup>203</sup> By 1970 power production from Larderello and surrounding fields was 384,000 kilowatts, and the total from plants in Japan, Mexico, New Zealand, Soviet Union and the United States added 300,000 more kilowatts, bringing the total to 684,000. Additional capacity or new plants planned in El Salvador, Guadeloupe, Iceland, Japan, Mexico, New Zealand, Taiwan, Turkey, the United States and the USSR were expected to bring total output to over one thousand megawatts.<sup>204</sup> It is believed that in the Soviet Union, some 50-60 per cent of the territory contains thermal waters that are comparable in energy to all the coal, peat and fuel resources of the country combined.<sup>205</sup> In northern California, the geysers field has a potential capacity estimated at 3 million kilowatts, and surveys in the Imperial Valley of southern California suggest a potential of 20 million kilowatts.<sup>206</sup>

88. In addition to electric power, the geothermal fields have provided man with a number of useful products. Geothermal steam or hot water has been applied in the desalination of sea-water, for heating houses, greenhouses, swimming pools as well as for refrigeration, air conditioning and a wide range of industrial uses in mining, manufacturing and agriculture. Moreover, the hot water itself can serve to provide potable water. The technology and economics of a multipurpose development of geothermal resources have been envisioned and planned in a number of schemes in recent years.<sup>207</sup>

89. Nuclear power is also emerging as an important new source of energy<sup>208</sup> despite the fact that it has encountered some technical and economic impediments. For one thing, electricity generated from this source has difficulty competing with alternative sources based upon liquid fuels, owing to the falling prices of the latter.<sup>209</sup> Nevertheless, a number of nuclear plants and programmes are under way in several developed countries<sup>210</sup> and technological advances are constantly helping to improve the design of nuclear plants so as to make them economically more competitive in the large-scale generation of power.

90. Assessing the relation of new sources of energy to man, Dyson considers that in the very long run there is need for energy that is absolutely pollution-free: sunlight. In the fairly long run there is need for energy that is inexhaustible and moderately clean: deuterium. In the short run there is need for energy that is readily usable and abundant: uranium. And at present there is need for energy that is cheap and convenient: coal and oil.<sup>211</sup>

#### D. Factors affecting supply of natural resources

91. The natural resources available to a country at a given time depend upon the country's ability to draw upon both domestic and foreign sources, the latter through international trade. The domestic supply of a

---

lation are expected to be served. United Nations, *United Nations Symposium on the Development and Utilization of Geothermal Resources* . . . (1971), pp. 7-8.

<sup>208</sup> A number of authors have discussed the controlled release of energy from the two contrasting nuclear processes of fission and fusion. Fission involves the splitting of nuclei of heavy elements such as uranium. Fusion involves the combining of light nuclei such as those of deuterium. Among the relatively non-technical literature on the subject, see Libby, "Toward peaceful uses of the atom" (1959); Ubbelohde, *Man and Energy* . . . (1963), chap. 5; Hubbert, "Industrial energy resources" (1970), pp. 201-205; Jukes, "Nuclear energy and other recent development . . ." (1967); Hubbert, "Energy resources" (1969), pp. 219-233; Seaborg and Bloom, "Fast breeder reactors" (1970); Gough and Eastlund, "The prospects of fusion power" (1971); Tuck, "Outlook for controlled fusion power" (1971). Rose predicts that the fusion power will become available in appreciable quantity by the year 2000. Rose, "Controlled nuclear fusion . . ." (1971), p. 806.

<sup>209</sup> The application of nuclear energy to the large-scale transportation field, however, may prove to be economically feasible. A major project under study is a sea-level canal through the Panamanian Isthmus at an estimated cost of \$747 million. It was estimated in 1947 that the cost of such construction by conventional method would be \$5,132 million. Brooks and Krutilla, *Peaceful Use of Nuclear Explosives* . . . (1969), pp. 38-40.

<sup>210</sup> In the United States twenty-two nuclear plants are in operation, fifty-five are under construction and forty are on order. In 1971 about 1.4 per cent of total electrical energy in the United States came from nuclear fission. This figure was expected to reach 25 per cent by 1980 and about 50 per cent by the end of the century. Summers, "The conversion of energy" (1971), p. 157.

<sup>211</sup> Dyson, "Energy in the universe" (1971), p. 59. Hubbert, despite his belief in unlimited resources of energy, draws attention to the limits of growth. "It is as true of power plants or automobiles as it is of biological populations that the earth cannot sustain any physical growth for more than a few tens of successive doublings. Because of this impossibility the exponential rates of industrial and population growth that have prevailed during the past century and a half must soon ease." Hubbert, "The energy resources of the earth" (1971), p. 70.

given natural resource depends, in turn, upon its physical occurrence and the skill and technology with which it is worked and utilized. Thus, the supply of natural resources depends essentially upon three factors: physical occurrence of the resources (i.e., reserves), the level of technology and international trade.<sup>212</sup>

## 1. RESERVES

92. The concept of "reserves" is highly complex and gives rise to controversy, even among experts. Reserves are generally defined as deposits that can be mined, processed and marketed profitably under current economic and technological conditions. "Potential" ore denotes deposits that will become profitable at some future date, with progress in technology or higher prices, or a combination of the two.<sup>213</sup> Reserves can thus be defined as the assured volumes or tonnages that can be produced without financial loss under the existing technology and cost-price relationship. They are considered working inventory, as they represent only part of the total discovered. Thus, reserve estimates apply only at the time and under the prevailing conditions. As new discoveries occur, as costs or market prices fluctuate, or as technology is improved, so also the volume of reserves changes.

93. For these reasons, the amount of reserves can change very rapidly, as has been illustrated in a study by Schurr, which found that proven world reserves of crude oil more than tripled between 1950 and 1962. Schurr also found that four regions consisting of the Middle East, the United States, the Soviet Union, and the Caribbean area have about 90 per cent of the world's proven reserves. In the case of coal, China, Europe, the Soviet Union and the United States account for more than 90 per cent of the world's estimated recoverable resources. Most of Africa (except North Africa), most of South America and India do not have sizable amounts of either coal resources or proved oil reserves.<sup>214</sup> Thus, the distribution of these essential resources is markedly different from the distribution of world population.

## 2. STAGE OF TECHNOLOGY

94. Advancing technology,<sup>215</sup> while leading to a greater use of resources,<sup>216</sup> also adds to the supply.

<sup>212</sup> Slichter listed some of the means of increasing the supply of the world's metal resources: more efficient exploration techniques for discovering hidden deposits; improved technology in the mining and recovery of metals; higher prices; reduction of waste; substitution of other materials; more complete recovery of scrap metal; and perhaps reducing trade barriers in the interest of establishing a more efficient economy in the world as a whole. Slichter, "Some aspects, mainly geophysical, of mineral exploration" (1959), p. 374; and Hibbard, "Mineral resources: challenge or threat?" (1968).

<sup>213</sup> For definitions and classifications of reserves see, for example, Netschert and Landsberg, *The Future Supply of the Major Metals* . . . (1961), pp. 1-4; Thom, "The discovery, development and constructive use of world resources" (1964), particularly p. 498; Schurr *et al.*, *Energy in the American Economy, 1850-1975* . . . (1960), pp. 296-300; Lovejoy and Homan, *Methods of Estimating Reserves* . . . (1965), pp. 1-5.

<sup>214</sup> Schurr, "Energy" (1963), p. 120.

<sup>215</sup> Among many works discussing the effects of technological changes upon natural resources and man, see Mesthene, *Techno-*

The latter effect has been achieved by reducing the costs of exploitation, thus making possible the use of lower grade deposits or deposits which were not previously accessible because of cost considerations. It has also developed new processes which utilize materials formerly unusable, or which substitute for materials already in use.<sup>217</sup> Of much greater importance are the actual or prospective additions of formerly useless, or little used components of the natural environment to the list of useful natural resources. Granite, formerly used only for building, has become a potential fuel as a result of its uranium content, and air has become a natural resource of the chemical industry. Such materials as sea-water, clays, rocks and sands have also become resources to some degree.<sup>218</sup> In the past, improved technology has often succeeded in compensating for the depletion of higher grade ores. For example, as was pointed out in section A, the average grade of copper ore in the United States decreased during the first half of this century from 3 per cent to 1 per cent, yet the real price of copper in dollars of constant purchasing power at the end of the period was not very different from what it had been at the beginning.<sup>219</sup> Also, according to Demaree, recent developments in the use of electric furnaces and the conversion of ore to iron make it possible to cut the capital costs of steel making nearly in half.<sup>220</sup>

95. Advancing technology is said to often have a multiplier effect in expanding the volume of resources. United States reserves of uranium, for example, are currently estimated at some 250,000 short tons, which at the present

*logical Change* . . . (1970); and his "How technology will shape the future" (1968); Jarrett, ed., *Science and Resources* . . . (1959), particularly chaps. 3-5; Jantsch, *Technological Forecasting in Perspective* (1967), part 3; Hamilton, "Predicting technology's future" (1968); Bronwell, ed., *Science and Technology in the World of the Future* (1970), chaps. 1-8; Goldsmith, ed., *Technological Innovation and the Economy* (1970); Hoagland, "Technology, adaptation, and evolution" (1969); National Academy of Sciences, *The Impact of Science and Technology on Regional Economic Development* . . . <sup>220</sup> Demaree, "Steel . . ." (1971), p. 76.

level of technology may have an energy equivalent slightly above the total United States energy consumption in 1960. With a more advanced technology, the present uranium reserves might be equivalent to between ten and 100 or more times the 1960 energy consumption.<sup>221</sup>

96. Technological improvement in fission and the enlargement of sources of fission materials could meet energy needs for several millennia, while the development of feasible and economical ways of using fusion materials would virtually remove limits imposed by shortages of energy.<sup>222</sup> Given adequate supplies of energy resulting from the advance in technology, exploitation of heavy-volume minerals which abound in the surface of the earth (e.g., iron, aluminium) would become economically feasible,<sup>223</sup> and the cost of desalination and transportation of sea-water would be significantly reduced.<sup>224</sup>

97. The rate and direction of technological innovations is said to be partly accidental—the result of individual and unco-ordinated inventive efforts—but it is increasingly becoming dependent upon the extent and the nature of research and development carried out by the public sector or private sector.<sup>225</sup> The role of government is particularly important because of the effects of externalities and uncertainty involved in research and development expenditures.<sup>226</sup>

<sup>221</sup> Landsberg, *Natural Resources for U.S. Growth* ... (1964), p. 192; see also Hibbard, "Mineral resources: challenge or threat?" (1968), p. 145.

<sup>222</sup> According to McGann, while world reserves of fossil fuels might be exhausted in two centuries if world gross national product grows between 2 and 3 per cent annually, developments in fission material may extend the availability of mineral fuels another 1,000 years. McGann, "Technological progress and minerals" (1961), p. 74. On developments and prospects for nuclear energy see, for example, Seaborg and Bloom, "Fast breeder reactors" (1970); Artsimovich, "Controlled nuclear fusion ..." (1970); Hubbert, "Energy resources" (1969), pp. 218-233; Gough and Eastlund, "The prospects of fusion power" (1971); and Hammond, "Breeder reactors ..." (1971).

<sup>223</sup> McGann, "Technological progress and minerals" (1961); Landsberg, "Population growth and the potential of technology" (1968). On fossil fuel reserves, continuous sources of power and nuclear energy, see Hubbert, *Energy Resources* ... (1962), pp. 32-123.

<sup>224</sup> See communications on various aspects of desalination, submitted to the United Nations *Proceedings of the Interregional Seminar on the Economic Application* ... (1967).

<sup>225</sup> For a discussion of the definition, measurement, and other characteristics of research and development, see, for example, Organisation for Economic Co-operation and Development, *The Overall Level and Structure* ... (1967); United States, National Science Foundation, *National Patterns of R&D Resources* ... (1969), pp. 1-2.

<sup>226</sup> Mansfield argues that the market, if left to its own devices, would allocate too few resources to research and development. The risks and uncertainties involved to the individual investor in research and development are greater than the risks to society, since the results of the investment may be useful to someone other than the investor. For such reasons as these, a large proportion of expenditures on research and development stem from government agencies, private foundations and universities. The relevant question is whether this support that supplements that provided by the market mechanism is sufficient, too large or too small, and whether it is properly allocated. Mansfield, "Contribution of R&D to economic growth ..." (1972), p. 480. See also Arrow, "Economic welfare and the allocation of resources of invention" (1962); Nelson, "The simple economics of basic scientific research" (1959), pp. 297-306; and for a generalization see Debreu, *Theory of*

TABLE XI.12. RATIO OF RESEARCH AND DEVELOPMENT EXPENDITURE TO GROSS NATIONAL PRODUCT FOR SELECTED COUNTRIES, RECENT YEARS

Country	Year	Research and development expenditure as percentage of gross national product
USSR .....	1967	3.1
United States .....	1968	2.9
United Kingdom .....	1967	2.7
Germany, Federal Republic of .....	1967	2.7
France .....	1966	2.4
Canada .....	1966	1.4
Japan .....	1966	1.3
Norway .....	1967	1.2
Italy .....	1968	0.9

SOURCE: United States, National Science Foundation, *National Patterns of R&D Resources* ... (1969), p. 4.

98. Table XI.12 shows the ratio of research and development expenditure to gross national product in nine industrialized countries.<sup>227</sup> It is seen that the ratio ranges from 3.1 for the USSR to 0.9 for Italy.<sup>228</sup> Data for the United States show an increasing trend in research and development expenditure in relation to gross national product during recent decades; whereas this ratio was only 0.2 per cent in 1921,<sup>229</sup> it had risen to 2.9 per cent in 1968 (table XI.12). In most advanced industrialized countries, governments' expenditures on research and development are focussed on defence and space technology,<sup>230</sup> and there has been an awareness of underinvestment in some particular types of research and development in the civilian sectors.<sup>231</sup>

99. In assessing the effects of technological advances on the supply of resources, attention must also be given

*Value* ... (1959), chap. 7; Organisation for Economic Co-operation and Development, *The Overall Level and Structure* ... (1967), pp. 25-39; and Mansfield, *The Economics of Technological Change* (1968), chap. 6.

<sup>227</sup> Owing to the differences in definitions among countries, the ratio R&D/GNP may not be strictly comparable. United States, National Science Foundation, *National Patterns of R&D Resources* ... (1969), p. 4.

<sup>228</sup> For information on research and development expenditures in OECD countries, see Organisation for Economic Co-operation and Development, *Gaps in Technology* ... (1970), pp. 113-134.

<sup>229</sup> Nelson, Peck and Kalachek, *Technology, Economic Growth and Public Policy* (1967), p. 46.

<sup>230</sup> In the early 1960s in the United States, for example, over 55 per cent of the nations's research and development expenditures were for these purposes. Mansfield, "Contribution of R&D to economic growth ..." (1972), p. 480. In most developed countries, there have been considerable benefits to civilian technology—the "spillover", "spin-off", or "fall-out"—from military and space research and development such as the electronic computer, jet engine, atomic energy etc. *Ibid.*

<sup>231</sup> For example, in the United States, a presidential commission reported in 1966 that too little was being spent by the Government on research and development in the fields of urban transportation, pollution control and housing. Mansfield, "Contribution of R&D to economic growth ..." (1972), p. 481; United States, National Commission on Technology, Automation, and Economic Progress, *Technology and the American Economy*, vol. 1 (1966), p. 112; Nelson, Peck and Kalachek, *Technology, Economic Growth and Public Policy* (1967), p. 177; Mansfield, *The Economics of Technological Change* (1968), pp. 228-232.

to the possible adverse side effects of modern technology on the environment. The discovery of means for extracting energy from nature has led to increasing atmospheric pollution, and modern industrial development has been accompanied by significant increases in the pollution of both air and water which have caused a deterioration of man's resources and have had harmful consequences for human beings and other species. While coal burning has been responsible for large amounts of pollutants, a more recent energy source—the internal combustion engine—has been found capable of polluting the atmosphere with carbon monoxide much faster than fire.<sup>232</sup> Modern physics and chemistry have produced numerous pollutants,<sup>233</sup> including radioactive elements, detergents and pesticides, as well as industrial wastes.<sup>234</sup>

100. Efforts to reduce environmental pollution through stricter controls on industry have met with considerable success in particular areas, such as in the southern part of England (United Kingdom) since the implementation of the Clean Air Act of 1956.<sup>235</sup> Some scientists like Medawar have emphasized that the despoliation sometimes produced by technology is not an irremediable process, but rather a problem for which technology has found and will continue to find solutions.<sup>236</sup>

### 3. INTERNATIONAL TRADE

101. Since no country is nowadays self-sufficient in all resources, nations have come to rely on international trade to meet the growing demand for resources of their expanding industries. It has been seen in section C of this chapter that a large proportion of the world's mineral production is supplied by the developing countries (table XI.4), although an estimated 90 per cent of mineral consumption takes place in the industrialized countries. Thus, much of the production of minerals in the less developed countries is for export.<sup>237</sup> The United States, which formerly approached self-sufficiency in mineral resources, has become a fairly large net importer of such items as copper, lead, zinc, iron ore and lumber, as well as manganese, nickel, chromium and diamonds.<sup>238</sup>

102. So far as sources of energy are concerned, the industrialized regions supply most of their own needs for

solid fuels, gas and electricity,<sup>239</sup> but they are greatly dependent on trade with the developing regions for their supplies of oil. Table XI.13 shows that in 1969 net imports of crude petroleum accounted for over 90 per cent of supplies in Western Europe and Oceania, 66 per cent in Eastern Europe excluding the USSR, and about 12 per cent in North America. Only the Soviet Union, among the major industrialized regions, was a net exporter of oil.

TABLE XI.13. NET IMPORTS AND TOTAL SUPPLY OF CRUDE PETROLEUM, INDUSTRIALIZED REGIONS, 1969

Region	Supply (million metric tons)	Net imports (million metric tons)	Net imports as a percentage of supply
North America .....	610.18	70.76	11.6
Western Europe .....	547.67	527.62	96.3
Eastern Europe .....	52.57	34.68	66.0
USSR .....	265.85	-62.45	— <sup>a</sup>
Oceania .....	25.10	23.09	92.0

SOURCE: United Nations, *World Energy Supplies* ... (1971), table 8.

<sup>a</sup> Net exports amounting to 23.5 per cent of supplies.

103. Countries can import the materials they lack only to the extent of their ability to obtain foreign exchange, generally through their export proceeds. Developed countries usually rely mainly upon the sale of services and manufactured exports while developing countries rely often upon exports of agricultural products, raw materials and small manufactured goods.<sup>240</sup> Exploitation of domestic natural resources thus plays an even more strategic role in the economic development of the less developed countries than in the support of industrialized economies. It is the possibilities of exploiting natural resources for the export sector that has attracted capital, skilled manpower and advanced technology from the industrialized to the developing countries.<sup>241</sup>

104. The question has been raised as to whether specialization in the export of domestic resource products would achieve the adequate foreign exchange needed for imports and would thus enable the developing countries to increase their supply of other needed resources. In general, when a less developed country exports resource products, it may reap a large amount of foreign exchange from trade. At the same time, however, it not only loses the resources which are exported, but it is exposed to large shifts in the terms of trade, instability of real income, and possibly

<sup>232</sup> On the relative importance of different sources of carbon monoxide as an air pollutant, see, for example, Jaffe, "The global balance of carbon monoxide" (1970).

even action by importing countries to exploit their monopsonic situation.<sup>242</sup>

### E. Factors influencing demand for natural resources

105. The demand for natural resources is generally an indirect or derived demand which varies according to the extent that resources are used in the production of final products.<sup>243</sup> The major categories of natural resources, as described previously, differ substantially in their contribution to the economic activities of a country. In most countries, products of land greatly exceed in value those of all other raw materials and this is true even in economically advanced countries. In the United States, for example, in 1954 edible and inedible agricultural products made up about 84 per cent and minerals about 16 per cent of the total value of all natural resource products. In 1899, the corresponding percentages were 93 and 7.<sup>244</sup> In some economically less developed countries, minerals are even less important relatively than they were in the United States at the turn of the century, and agricultural products relatively more important. However, certain outstanding exceptions, such as the Libyan Arab Republic and Kuwait, deserve mention; in these countries the value of petroleum resources far exceeds that of agricultural products.

106. The long-term demand for natural resources depends on a number of factors, the principal of which are: population growth, average level of income, state of science and technology, price-cost structure and institutional patterns.

<sup>242</sup> Kindleberger, "International trade and investment . . ." (1961), particularly p. 186; Swerling, "Some interrelationships between agricultural trade and economic development" (1961), pp. 379-386. A controversy developed early in the 1950s over the contribution of international trade to the development of agriculture countries. Prebisch and Myrdal, among others, argued that the accrual of the gains from trade is biased in favour of the advanced industrialized countries and that, contrary to what would be expected from classical trade doctrine, free trade has in reality accentuated international inequalities. In contrast, Viner, Clark, Lewis, Haberler and others supported the traditional position that foreign trade can contribute substantially to the development of primary exporting countries, and that the gains from international specialization merge with the gains from growth. Hicks and Nurkse appear to have adopted a more neutral position. See United Nations, Economic Commission for Latin America, *The Economic Development of Latin America and its Principal Problems* (1950); Prebisch, "The economic development of Latin America and its principal problems" (1962), pp. 4-6; United Nations, *World Economic Survey, 1958* (1959), chap. 6; Viner, *International Trade and Economic Development* (1952); Clark, *The Economics of 1960* (1942), and his "Halfway to 1960" (1952); Lewis, *Economic Survey, 1919-1939* (1949), and his "World production, prices and trade . . ." (1952); Haberler, "Terms of trade and economic development" (1961); Hicks, *Essays in World Economics* (1959), pp. 180-188; and Nurkse, "International trade theory and development policy" (1961), pp. 234-245. See also MacBean, *Export Instability and Economic Development* (1966), parts 1 and 4, and his "Foreign trade aspects of development planning" (1969); and Meier, *The International Economics of Developments . . .* (1968), chap. 3.

<sup>243</sup> For a statement in terms of "elasticities", see Kindleberger, "International trade and investment . . ." (1961), pp. 154-156.

<sup>244</sup> University of Maryland, Bureau of Business and Economic Research, "Some relationships between U.S. consumption and natural resources, 1899, 1947, 1954" (1958), p. 6.

## 1. GROWTH OF POPULATION

107. The demand for natural resources depends *inter alia* on the size and distribution of population. A growing population means a greater demand for resources of all kinds, for food, water, air, mineral resources, construction materials, and space for a variety of purposes.<sup>245</sup> On the other hand, the distribution of the population as between urban and rural areas, and agricultural and non-agricultural economic activities, influences the nature of demand for resources, since a highly urban, non-agricultural population requires, *inter alia*, less land but more industrial raw materials and supplies of energy *per capita* than an agricultural population. World population growth has recently shown a rapid acceleration and there has been an increasing concentration of population in urban areas, particularly in large metropolitan centres. Each addition to the population means an additional increment of basic resource necessities, such as food, water, shelter and space. But, in addition, man is said to be in the midst of a "revolution of rising expectations", the nature of his increasing demands depending on his tastes and preferences and his ability to satisfy them.<sup>246</sup> The result has been a universal commitment to the concept of economic growth and to an increase in *per capita* production and consumption.<sup>247</sup>

108. As discussed previously, a considerable number of authors have expressed the belief that the increasing use of natural resources as a result of population growth has a tendency to lower the future standard of living, even in areas generously endowed by nature.<sup>248</sup> Some of these fears derive from the Malthusian notion that land and other resources are scarce and tend to be pressed upon by population growth; others are based on the Ricardian concept that resources are used in order of declining quality, with the result that diminishing returns accompany population growth. Various writers have pointed out that experience in the advanced countries indicates fallacies in these arguments. In these countries, birth rates have fallen, the capital stock has increased faster than population numbers, and natural resources, far from being fixed in volume, have increased as a result of technological advances. Looking ahead to the time when all nations will have made advances in economic development, Barnett saw no reason for believing that diminishing returns would set in as a result of population growth, or that there would be a shortage of natural resources for production of extractive goods.<sup>249</sup>

109. The past experience of the developed countries, as reflected in their statistical data, shows that it has been possible to expand resource materials at a faster natural

<sup>245</sup> Keyfitz, "United States and world populations" (1969), p. 58.

<sup>246</sup> Chapman, "Interactions between man and his resources" (1969), particularly p. 32.

<sup>247</sup> On man's commitment to economic growth as an "irreversible and irrepressible need" see Jaguaribe, "World order, rationality, and socio-economic development" (1966), p. 612. Boulding, however, argues for the necessity in the future of a type of economy based not on maximization of production and consumption, but on improving the quality of environment and life. Boulding, "The economics of the coming spaceship earth" (1966).

<sup>248</sup> See section B.

<sup>249</sup> Barnett, "Population problems—myths and realities" (1971).

rate than population has grown. In the United States, for example, during 1870-1957, while the population increased fourfold, mining of bituminous coal increased eighteenfold, extraction of iron ore increased twenty-sixfold, extraction of copper ores seventy-sevenfold and output of crude petroleum increased four hundred ninetyfold.<sup>250</sup> Data on *per capita* consumption of resource products show a steadily upward trend, increases being most rapid during the early part of the period. The average *per capita* rate of growth of mineral consumption, for example, was about 4.5 per cent per year during the last part of the nineteenth century, whereas it fell to between 1.5 and 2 per cent thereafter.<sup>251</sup>

110. Projections of future demand for natural resources are clouded with uncertainties concerning the trends of population growth, future gains in technology, and other conditions such as the flow of world trade.<sup>252</sup> Looking ahead to the end of the century and assuming a 50 per cent increase in population for the United States and about a threefold increase in gross national product, Fisher calculated rough estimates of resource demand. His projections show the following increases over 1970 levels: total energy requirements, one and a half to two times; electric power, six times or so; iron ore, more than double; aluminium, five times or more; copper, double or more; timber, more than double; fresh water, withdrawn and not returned, one and a half times; wheat, one-quarter to one-third; cotton, one and a half times, or more.<sup>253</sup> According to estimates of the Commission on Population Growth and the American Future, the demand for minerals in the year 2000 in the United States would be 9 per cent less if families averaged two children rather than three.<sup>254</sup>

111. For the world as a whole, projections by Fisher and Potter suggest that energy consumption in the year 2000 may be four to six times the 1965 level, iron ore consumption perhaps four times, and copper three times. Since during the same period, world population was projected to increase at only slightly more than 100 per cent,<sup>255</sup> it is clear that factors other than population accounted for the major part of the expected increased demand for the resource products mentioned.

<sup>250</sup> Potter and Christy, *Trends in Natural Resource Commodities* ... (1962), p. 1.

<sup>251</sup> Fisher and Potter, "Natural resource adequacy ..." (1969), pp. 110-111; Potter and Christy, *Trends in Natural Resource Commodities* ... (1962), pp. 8-9.

<sup>252</sup> Landsberg, *Natural Resources for U.S. Growth* ... (1964), pp. 6-7.

<sup>253</sup> Fisher, "Impact of population on resources and the environment" (1971), p. 393. See also projections in Landsberg, *Natural Resources for U.S. Growth* ... (1964), chap. 3, and Landsberg, Fischman, and Fisher, *Resources in America's Future* ... (1963), particularly pp. 16-41.

<sup>254</sup> United States President. Commission on Population Growth and the American Future, *Population and the American Future* ... (1972), p. 58.

<sup>255</sup> Fisher and Potter, "Natural resource adequacy ..." (1969), pp. 126-127 and table 2. See also their *World Prospects for Natural Resources* ... (1964), chap. 4.

112. The rate of economic growth, as reflected in *per capita* income, is among the major determinants of the demand for resources. With reference to the United States, it has been observed that regardless of future population growth, expected increases in output are likely to result in tremendous increases in demand for resources.<sup>256</sup>

113. It is known that demand for some resource products increases faster proportionately than the average income of the population while that for others increases relatively slower.<sup>257</sup> Where income is low, it has generally been found that there is a tendency to spend a large part of any increment in income on primary products. In the long run, however, as average income rises, increasing proportions of further gains in income are spent on services and other products. The historical experience of industrialized countries of Western Europe and North America shows that, with a rise in real incomes there is a relatively rapid rise in demand for capital goods, chemicals and durable consumer goods, and a relatively slow expansion in the demand for food, beverages, tobacco, textiles and clothing.<sup>258</sup> International comparisons indicate that income elasticities of demand for food are considerably higher in developing countries than in the more industrialized countries.<sup>259</sup> Owing both to fast population growth and high income elasticities of demand, food consumption demand in developing countries is likely to increase rapidly in the coming decades.<sup>260</sup>

114. While both population and economic growth are universally acknowledged to be influential factors in determining the demand for natural resources, there are some differences of opinion as to their relative importance. According to the findings of the Commission on Population Growth and the American Future, in the year 2000,

<sup>256</sup> United States President. Commission on Population Growth and the American Future, *Population and the American Future* ... (1972), p. 57.

<sup>257</sup> This is conveniently expressed in terms of income-elasticity of demand, which can be computed for various resources and goods in a country. The income elasticity of demand shows the responsiveness of a consumer's purchases of a particular product to a change in his income. See, for example, Kindleberger, "International trade and investment ..." (1961), particularly pp. 154-155.

<sup>258</sup> Maizels, *Industrial Growth and World Trade* ... (1963), p. 41.

<sup>259</sup> Income elasticities in the range of 0.5 to 0.8 have been found in some more developed countries. See, for example, Maizels, *Industrial Growth and World Trade* ... (1963), p. 42; Houthakker, "An international comparison of household expenditure patterns ..." (1957); and Dewhurst *et al.*, *Europe's Needs and Resources* ... (1961), p. 969. Clark and Haswell considered that the income elasticity ratio for food, which was sometimes thought to approach 1.0 in very poor countries, was actually below this level. They noted claims of a ratio of 0.9 for India, but believed this figure subject to an upward bias. Clark and Haswell, *The Economics of Subsistence Agriculture* (1970), pp. 172, 177. See also the much lower values estimated for both developing and developed countries in Organisation for Economic Co-operation and Development, *The Food Problem of Developing Countries* (1968), p. 15.

<sup>260</sup> Organisation for Economic Co-operation and Development, *The Food Problem of Developing Countries* (1968), p. 15. See also chapter XII, sections B and D.

if gross national product *per capita* were 1 per cent less than projected, the consumption of most minerals would be 0.7 to 1.0 per cent less; however, if population were 1 per cent less than projected, minerals consumption would be 0.5 to 0.7 per cent less. The effect of slower population growth, while substantial, is smaller than might be expected, owing to the fact that a lower rate of population growth implies a different age structure with a more favourable ratio of labour force to total population, and hence higher output *per capita*.<sup>261</sup> Spengler, however, has argued in more general terms that the demand for total resource services stemming from population growth progresses at about the same rate as population, whereas the elasticity of demand associated with growth of *per capita* income tends to fall.<sup>262</sup>

### 3. STAGE OF TECHNOLOGY

115. While technological achievement is usually given credit for widening the supply of resources (see section D above), it may also lead to a greater demand for resources. Chapman has pointed out that the enormous requirements of some technologies in themselves contribute greatly to the depletion of resources and the production of waste.<sup>263</sup>

116. Some technological developments have the effect of increasing the demand for particular resources, while others decrease such demand. For example, the advent of the automobile and the consequent development of highway systems, suburban living arrangements and shopping centres have tended to increase the demand for land; on the other hand, many technological advances in agriculture have decreased the demand for land.<sup>264</sup> Thus, if corn yields had not increased after the 1940s, it would have taken nearly 100 million acres to produce the crop that was actually grown on 57 million acres in 1962 in the United States.<sup>265</sup>

117. The advances that have been made in the efficiency of resource use suggest how resource demand may be influenced in the future by further technological innovations. For example, the amount of fuel required for the production of one kilowatt-hour of electricity declined from 6.85 pounds of coal or coal equivalent in 1900 to only 0.95 pounds in 1955.<sup>266</sup> The effect that changes in technology can have on demand for fuels is illustrated in the following calculations prepared by Landsberg for the year 2000:<sup>267</sup>

<sup>261</sup> United States President. Commission on Population Growth and the American Future, *Population and the American Future* ... (1972), p. 58.

<sup>262</sup> Spengler, "Summary, synthesis and interpretation" (1961), p. 301.

<sup>263</sup> Chapman, "Interactions between man and his resources" (1969), p. 38.

<sup>264</sup> White, *Social and Economic Aspects of Natural Resources* (1962), p. 9.

<sup>265</sup> Landsberg, *Natural Resources for U.S. Growth* ... (1964), p. 25.

<sup>266</sup> White, *Social and Economic Aspects of Natural Resources* (1962), p. 10.

<sup>267</sup> Landsberg, *Natural Resources for U.S. Growth* ... (1964), p. 28.

Projected fuel requirements  
in the United States  
in the year 2000 assuming

	Continued gains in efficiency in the production of electricity	No gains beyond 1960 in efficiency in the production of electricity
Natural gas (thousand million cubic feet)	3,480	4,800
Coal (million short tons)....	455	640
Oil (million barrels) .....	135	185

Thus, without continued gains in the efficiency of producing electricity, demand for natural gas, coal and oil might be around 40 per cent greater by the end of the century than could be expected with continued gains in efficiency. In view of the great influence that technological change may exert upon the demand for resources, Landsberg noted that inability to make allowances statistically for possible radical innovations in methods of production constitutes the most serious weakness of resource requirement appraisals.<sup>268</sup>

### 4. PRICE-COST STRUCTURE

118. Price-cost changes in raw materials are reflected throughout the economic structure, from producer at each stage of the production process and ultimately to the consumer. Hibbard has said that "raw materials are powerful economic multipliers". However, the price mechanism has not always proved to be adequate to spur the necessary investments.<sup>269</sup> Changes in price structure affect the demand for specific resources within such major resource categories as food, fuel and other raw materials, although they have little effect on the volume of aggregate demand for each major category. If the relative price of one product rises, other conditions remaining equal, consumers are likely to substitute another product to some extent in their purchases, with the result that the demand for natural resources used in producing this product tends to fall. Similarly, a rise in the cost of a natural resource is likely to cause it to be partially replaced in the production process by another natural resource or by labour or man-made capital. In the United States, for example, as lead became a relatively higher priced commodity, plastics began to supplant lead.<sup>270</sup> A large decline in the price of aluminium—a close substitute for copper—was undoubtedly an important factor in checking the growth rate of the demand for copper after the Second World War.<sup>271</sup>

119. Competition among resources resulting from substantial, persistent changes in the price structure are most important in the case of resources such as fuels and metals, which can relatively easily be substituted for one

<sup>268</sup> Landsberg, *Natural Resources for U.S. Growth* ... (1964), pp. 27-28.

<sup>269</sup> For example, substantial capital and a number of years are required to complete a new mineral-producing facility. Hibbard, "Mineral resources: challenge or threat?" (1968), p. 144.

<sup>270</sup> United States, President's Materials Policy Commission, *Resources for Freedom*, vol. 1 (1952), p. 10.

<sup>271</sup> Herfindahl, *Copper Costs and Prices* ... (1959), pp. 226-227.

another.<sup>272</sup> As technology changes, so do costs and competitive relationships. Competition among fuels, in particular, is said to be a complex of economic, technology and political forces.<sup>273</sup>

## 5. INSTITUTIONAL PATTERNS

120. Some writers have dealt with the attitudes of different peoples toward their natural environment, and the implications of such attitudes for the exploitation of natural resources. Spoehr has noted that in many non-western, pre-industrial societies, man is regarded as part of a natural environment over which he has little control. In contrast, western concepts tend to regard nature as something apart from man that should be developed as fully as possible through the application of technology to meet man's needs and wants.<sup>274</sup>

121. Within the over-all pattern of resource consumption in a given society, there is a diversity of tastes and preferences among individual consumers, once the levels of income and price structure have been specified. In industrially developed countries, it is generally possible to meet one's resource needs among a number of alternatives, but often the consumer simply "prefers" one over the other, with the result of influencing the demand for that particular resource.<sup>275</sup> Allowances thus have to be made for the international diffusion of tastes and preferences, which can produce changes in the composition of a country's demand for natural resources as well as in the level of world demand for a particular resource.

122. Changes associated with industrialization have in some countries resulted in the production of a multiplicity of consumer goods and led to a situation where such items as telephones, motor vehicles, airplanes, and newsprint, which formerly had been luxuries, have become necessities. Such consumption patterns, of course, greatly affect the demand for resource products.<sup>276</sup>

<sup>272</sup> There is said to be increasing competition for steel from aluminium, plastics and pre-stressed concrete. If and when cheap electric power becomes available, the cost of aluminium may drop relative to that of steel, giving the former a competitive advantage. United Nations, Economic Commission for Europe, *Long-Term Trends and Problems of the European Steel Industry* (1959), p. 138. On interfuel competition, see United States, National Fuels and Energy Study Group, *Report on an Assessment of Available Information on Energy ...* (1962), pp. 274-294.

<sup>273</sup> United States, National Fuels and Energy Study Group, *Report on an Assessment of Available Information on Energy ...* (1962), p. 274.

<sup>274</sup> Spoehr, "Cultural differences in the interpretation of natural resources" (1956), particularly pp. 98-101.

<sup>275</sup> In the United States, for example, "despite the fact that natural gas and heating oil are more expensive than coal in some areas, they are preferred by householders to such an extent that they have taken over a large segment of the space-heating market. Gas is taking away markets from oil for the same reason—simple preference." See United States, National Fuels and Energy Study Group, *Report on an Assessment of Available Information on Energy ...* (1962), p. 284.

<sup>276</sup> Thus in the United States some 1,300 pounds of new steel are produced each year per person. Brown, "Population, food and energy transition" (1969), pp. 181-182.

## F. Relation of natural resources and population to development

123. The size and characteristics of a country's population in relation to its resources are believed to exert a substantial influence on the country's prospects for development. Resources, in general, set certain limits to what may be accomplished in combination with manpower, capital and the state of technology. While the magnitude of resources is hardly ever known precisely at any given point in time, the unequal distribution of resources with respect to area and population is well known. Because of the inequality of world resource distribution, the prospects for economic and social development are likely to be brighter in areas that are relatively well-endowed with resources than in others which are not.

124. Some authors attach greater importance than others, however, to the possession of natural resources as a prerequisite for development. Kuznets, for example, regards physical resources as relatively unimportant, stating that the factors that induce formation of reproducible capital needed for economic growth are not likely to be inhibited by a lack of natural resources.<sup>277</sup> Lewis, however, states that since capital is not a perfect substitute for natural resources, such as land, water and minerals, a shortage of natural resources can be an obstacle to economic development.<sup>278</sup> Most writers would no doubt agree that possession of a variety of natural resources is advantageous, though not decisive for economic development.<sup>279</sup>

125. Hartshorne has suggested a twofold classification of factors which are necessary for economic development: (a) material factors, which consist of raw materials, transport facilities, other capital goods (machine and plant equipment) and power sources; and (b) human factors, including entrepreneurship, money capital, labour and markets. He noted that a lack of material factors does not in itself preclude economic growth, since all of these factors are available elsewhere and can be imported, provided the country can produce sufficient surpluses

<sup>277</sup> Kuznets, "Toward a theory of economic growth" (1955), p. 36. He also observed that scarcity of natural resources in underdeveloped countries is primarily a function of their underdevelopment, and the latter is not a function of scarce natural resources. Kuznets, "Population and economic growth" (1967), p. 174.

<sup>278</sup> Lewis, "Employment policy in an underdeveloped area" (1958), p. 46.

<sup>279</sup> See, for example, Mountjoy, *Industrialization and Underdeveloped Countries* (1966), p. 25. The author noted that certain countries well-endowed with resources, such as Brazil, are not very highly developed, while other countries such as Denmark and Switzerland, with limited resources, are highly advanced. Abramovitz observed, however, that among countries having similar institutions, culture and technology, the presence of resources seems to have an influence on income levels. Thus, such countries as Australia, Canada, New Zealand and the United States, which are richer in resources, have generally higher *per capita* incomes than most of the countries of Northern and Western Europe. Abramovitz, "Comment" (1961), p. 14. Attention has sometimes been called to the geographical disadvantages for development of certain countries, resulting from their climate, soils or topography. With respect to the factor of climate in particular see Myrdal, *Asian Drama ...*, vol. 1 (1968), pp. 678-681; Lee, *Climate and Economic Development in the Tropics* (1957).

of other products needed elsewhere.<sup>280</sup> Thus, it is the accessibility of resources rather than their presence in a country that counts most for economic development.<sup>281</sup> The non-material, or human factors, which every country has a potential for developing within its own population, are considered to be more essential for economic growth. To develop this potential through education and training is one of the major challenges that developing countries face.<sup>282</sup>

126. It has been observed that during the early stages of industrial growth of the presently developed countries, their rate of economic growth was often affected by changes in the available supply of resources. Wrigley has pointed out that the removal of constraints against raw materials supply was closely connected with the rapid growth of England's economy toward the end of the eighteenth century. It became possible to substitute inorganic raw materials such as coal—the supply of which could be more rapidly expanded—for organic materials, such as wood.<sup>283</sup> In the United States the availability of rich agricultural and mineral resources facilitated

<sup>280</sup> Hartshorne, "Geography and economic growth" (1960), p. 18; see also his "The role of the state in economic growth . . ." (1959), pp. 296-321.

<sup>281</sup> Herfindahl, *Natural Resource Information for Economic Development* (1969), p. 4. Myrdal, however, warned that developing countries will encounter difficulties in relying on imports of raw materials at the beginning of their development. Myrdal, *Asian Drama . . .*, vol. 1 (1968), p. 677.

<sup>282</sup> Hartshorne, "Geography and economic growth" (1960), p. 19. Among many articles dealing with education and manpower training requirements in developing countries see, for example, Harbison, "Human resources development planning in modernising economies" (1962); Bowman and Anderson, "The role of education in development" (1962); United Nations Economic Commission for Africa and UNESCO *Conference of African States on the Development of Education in Africa . . .* (1961); Schultz, "Education and economic growth" (1961).

<sup>283</sup> Wrigley, "The supply of raw materials . . ." (1962), particularly pp. 1-6.

internal development and attracted capital and labour from abroad.<sup>284</sup>

127. The outlook for development in the newly emerging countries depends on a variety of factors, among them the limits that scarce resources may impose on productivity gains, the rate of technological advancement and the rate of population growth. Spengler noted several favourable recent trends which have given rise to some optimism: (a) investment in scientific discovery, applied technology and education has been found to account for the major increase in output in advanced countries; (b) input of land and natural resources per unit of output has greatly decreased in advanced countries; and (c) technological change and substitution have greatly augmented stocks of fuels, minerals and related resources. In Spengler's opinion, however, the favourable experience of advanced countries may be given too much weight in assessing prospects for developing countries and insufficient attention given to the difficulties encountered by developing countries and the depressing effects of population growth.<sup>285</sup> Kuznets observed that the relative scarcity of natural resources in some underdeveloped countries might be so acute that the pressures of further population growth could not be borne even by advanced technology.<sup>286</sup> According to White, the developing countries may reach the end of the century with continued high birth rates and a low level of *per capita* consumption that may keep them on the verge of subsistence. But, on the other hand, through progress in family limitation and the beginning of technological take-off, they may be able to achieve self-sustained economies.<sup>287</sup>

<sup>284</sup> See, for example, Youngson, "The opening up of new territories" (1965), particularly pp. 144-181.

<sup>285</sup> Spengler, "The economist and the population question" (1966), p. 9.

## Chapter XII

### POPULATION AND FOOD

1. Food, clothing and shelter are among man's basic needs, but even more than the others, food is essential for day-to-day survival. While the scarcity of clothing and shelter is likely to cause misery, the scarcity of food often has more severe consequences, manifesting itself in undernutrition and malnutrition and, in cases of acute shortages, in sickness, starvation and premature death. The satisfaction of the minimum requirements for food and nutrition are thus at the root of the survival and well-being of the individual and the society. The struggle to secure enough food to assure his daily subsistence, and often his failure to do so, have dominated man's destiny for a long time. The food problem, arising from the effect of the food requirements of a rapidly growing population, therefore, has been and continues to be a source of widespread preoccupation.

2. It is generally recognized that the actual and potential sources of food supply, even though as yet not fully known, are not unlimited and that ultimately population will be checked by the limits of food supplies. At the same time it is generally agreed that the actual population of the world and its different parts is in varying degree still below these limits. Although this essentially long-term concept of the carrying capacity of the earth has also influenced thinking on the population and food problem in a shorter time perspective, it is not a major issue at the present time. The immediate problem in the relation between population and food is whether the actual production of food, as opposed to the potential, can satisfy the requirements and effective demand for it created by a rapidly growing population. Especially in the developing countries, where population growth has accelerated to unprecedented levels and nutrition and food consumption are often deficient, food requirements and demand have grown at very high rates. Although the growth of population in these countries adds to their labour force, there is no assurance that these rapidly increasing requirements and demand will be met by higher production or supply. Such a growth in production would only be possible with considerable investments in land, material equipment and labour, technological progress and institutional changes, conditions which are often difficult to meet in these countries. A rapidly increasing labour force under the prevailing circumstances may lead to growing underemployment, an increasing pressure on other resources, stagnating productivity and a less than proportionate increase in agricultural and food production. The food problem created by rapid population growth is, therefore, part of the general problem of over-all and agricultural underdevelopment, the solution to which must be sought both

in accelerating development and slowing down the growth of population.

3. The purpose of this chapter is to present a general review of the state of knowledge concerning the relations between population and food. The first section contains a brief sketch of the historical evolution, present situation and possibilities of finding solutions to the population and food problem. The next two sections are concerned with the effects of demographic factors on the requirements and actual demand for food and on the supply of food, respectively. The first of these includes a discussion of trends in food production and supplies in relation to population, the prevailing levels of nutrition and the role of demographic factors in determining the effective demand for food. The second focuses on the relations between population and the productivity of land and agricultural labour as the two basic factors related to the absolute and relative levels of agricultural and food production. It concludes with some comments about the possibilities of increasing food production and supplies. The final section of the chapter deals briefly with the outlook for future food production and demand and their reconciliation, with special reference to the impact of demographic factors on total food requirements and demand.

#### A. The population and food dilemma

4. It is generally recognized that population and food are closely interrelated, even to the extent that at times the population problem has been identified as a food problem. In effect, during the greater part of man's history the number of people has been regulated by the availability of food and for most of these times the balance between population and food has been a precarious one. The development of agriculture and increasing food supplies in more recent centuries were among the main factors which made possible the accelerated growth of population characteristic of the modern period. Even so, food shortages which acted as a check to the increase of population were eliminated only in the relatively small group of more developed countries. In most other parts of the world, little if any progress was made in increasing supply relative to the demand for food and in improving levels of nutrition. Rapid population growth in recent decades and the prospects of its continuation in the future in most of these countries, coupled with their desire for improved and satisfactory levels of nutrition as part of their aspirations for development, has brought the population-food problem again to the centre of attention.

induced by population growth will become an effective demand only if total production and income expands at least at the same rate as population. If total production does not expand at all or expands more slowly than population, causing *per capita* income to fall, total demand for food may increase less than population and levels of nutrition may decline.<sup>98</sup> For this reason, and because of the more complex effects of income on the demand for food and its structure, the income factor, it is sometimes argued, is the most important of the two.<sup>99</sup> Nevertheless, projections of the demand for food based on certain assumptions of growth of income and population and elasticities of the demand for food indicate that for the world as a whole, as well as in developed and developing regions, population growth was found to be a more important factor than *per capita* income in the expected future increase of demand for food.<sup>100</sup>

41. In addition to population growth, changes in population composition and structure are thought to influence the demand for food. Since the needs of persons of different sex and age differ, the sex and age distribution of the population will tend to affect food requirements and total demand as well as the demand for individual foods.<sup>101</sup> It has been noted, for instance, that the high proportion of young children in developing countries may lower calorie requirements somewhat, but that this effect is probably outweighed by the greater need for proteins of children and young adults.<sup>102</sup> However, in practice this effect may be small. According to Sukhatme and Schulte, estimated changes in the sex and age structure, considering existing population trends, might cause changes of less than 10 per cent in calorie requirements and even less than that in proteins.<sup>103</sup> Related to the effect of the age distribution is the influence of the size of the household on the demand for food. Differences in this respect, as discussed in another chapter,<sup>104</sup> depend to a considerable extent on the existence of economies of scale and indications are that *per capita* expenditure on food decreases as the size of the family increases.

42. Among the demographic factors affecting the demand for food, the rural-to-urban migration and the urban-rural distribution of the population are generally thought to be important. Being associated with a shift from agricultural to non-agricultural activities, changes in the level of income and increased emphasis on non-food products and services, urbanization is considered as

likely to have an impact on the demand for food. This effect may be especially strong in the developing countries, where urbanization is rapid, and implies a shift from the subsistence to the market economy and, where large increases occur in the non-farm population, in the volume of food marketed and in relative food prices.<sup>105</sup> Even so, the influence of urbanization itself on patterns of food consumption and demand—apart from the influence of income differentials between urban and rural populations—is not clear. Various studies, for instance, suggested that, on the whole, urban diets were qualitatively somewhat better than rural ones, while others did not show a marked difference in food consumption between urban and rural groups with comparable incomes.<sup>106</sup>

### C. Population and agriculture

43. Whereas section B above reviewed aspects of the population and food problem related to population in its role as consumer, the purpose of the present section is to examine some of the principal implications of demographic factors for agricultural production and development. The effects of demographic factors on agricultural production and development are diverse and an exhaustive survey of the complex of direct and indirect influences is beyond the scope of this study, particularly since such relations are to a great extent conditioned by the stage and process of over-all development. Therefore, the following discussion is confined to major aspects of this problem. The first part of this section is concerned with the relations between population, on the one hand, and the amount of agricultural land and its productivity, on the other. As the primary determinants of the volume of agricultural production, these factors are of special relevance for those countries faced with actual or potential shortages, where increasing the total amount of food produced is of the first priority. However, the long-term solution of the food problem and, for that matter, the whole problem of under-development can only be attained through raising the productivity of agriculture and agricultural labour, which not only ensures an adequate food supply, but raises the levels of living of the agricultural population and the degree of employment of its labour force and makes possible the transfer of workers necessary for the development of the non-agricultural sectors of the economy. The second part of this section considers some general aspects of the relations between population and the productivity of agricultural labour as one of the basic indicators of the level of agricultural development.

44. Empirical comparisons and verifications of such relationships are seriously hampered by the scarcity and shortcomings of data as well as difficulties in their interpretation. The measurement of agricultural land and labour, the productivity of each, and the interpretation

and significance of such concepts as density, under-employment, to name but a few aspects, are subject to severe qualifications. Consequently, the present state of knowledge is much less than complete and there are many gaps as regards the relationships between population and the growth and development of agriculture. Even so, the analysis of the available data may be useful for the purpose of broad comparisons and as a factor in formulating policies and programmes.

# 1. AGRICULTURAL LAND AND ITS PRODUCTIVITY

45. Agricultural production can be increased either by enlarging the area under cultivation or by raising the yields of the existing agricultural land.<sup>107</sup> Historically, little is known concerning the relative importance of increases in agricultural land as opposed to higher productivity of the land already in use in determining agricultural production. As has been noted before,<sup>108</sup> it is generally assumed that during the greater part of history the growth of agricultural output was to a very large extent the result of the spread and expansion of agriculture, while—at least until the Industrial Revolution—the productivity of land is thought to have changed relatively little. In more general terms it is usually held that as population increases, more land will be brought under cultivation in order to feed the larger population. Recent trends do not necessarily confirm such a hypothesis, especially where the more developed regions are concerned. The available data suggest that in these regions the growth in production was exclusively the

<sup>107</sup> Agricultural land can be increased by adding to the area harvested or through multiple cropping.

<sup>108</sup> See section A of this chapter. Also Brown, *Man, Land and Food* ... (1965), p. 100; McCormack, *The Population Problem* (1970), p. 54.

result of a rise in yields, as the area under cultivation remained stable and, in fact, even declined somewhat. The situation is different in the less developed regions, where the expansion in agricultural land has been a significant factor in the growth of output. But even in this group of countries, the contribution of higher yields to the growth in production has risen very fast in recent decades and become the predominant factor.

46. Percentage changes in production, cultivated area and average yields per hectare of twelve major crops<sup>109</sup> are presented in table XII.9 for different periods since the Second World War. According to these estimates, world production of these crops has, to an increasing extent, been dominated by rising yields. While the rate of growth of the latter remained relatively stable over the period considered, although registering an increase in the more recent period, the relative growth of the area under cultivation declined and, as a result, the contribution of the change in yields to the growth of production rose from an estimated 61 per cent between 1948-1952 and 1957-1959 to 88 per cent between 1964-1966 and 1969-1971. These world-wide trends reflected different developments in the more developed and less developed regions. In the former, the area under cultivation did not change much—particularly after the late 1950s—the only exception being Oceania. In the other developed regions the cultivated area actually contracted during recent periods, so that gains in yields accounted for more than the increase in total production. In contrast, in the developing countries the expansion of area under cultivation was much more important and the area planted with these crops increased significantly during the post-war period. But even in these regions the rate of expansion of

<sup>109</sup> The selected crops were: wheat; rye; barley; oats; maize; rice; potatoes; ground-nuts; soybeans; tobacco; cotton; and jute.

<sup>a</sup> Excluding China.

<sup>b</sup> Price weighted.

<sup>c</sup> Percentages over 100 indicate that production has increased despite a reduction in area.

the area under cultivation slowed down significantly, except for Africa, over the whole period considered. Since at the same time yields increased, the contribution of the higher productivity of land to the growth in production rose sharply. Whereas between 1948-1952 and 1957-1959 only some 34 per cent of the increase in the production of the selected group of crops in the latter regions could be attributed to rising yields, between 1964-1966 and 1969-1971 this factor accounted for 62 per cent of the growth in output. Similar data for earlier periods relating to the same twelve products, or total grain production, also suggested, in general, that the growth of production in the developed regions was entirely due to increases in yields, whereas in the developing regions the area under cultivation was the main factor in the increase of production, but that its importance was declining as time progressed.<sup>110</sup> Although the trend towards a growing importance of increasing yields in developing countries may be interpreted as an indication of an existing or imminent scarcity of land in these regions, or parts of them, in absolute terms agricultural land is not scarce in the sense that there would be no longer large areas which could be brought into productive use.

47. The estimated area actually under cultivation represents somewhat over 10 per cent of the world's total area,<sup>111</sup> but most writers agree that this area could still be considerably expanded.<sup>112</sup> According to an early estimate by Fawcett, often cited since then, some 30 per cent of the total land area, or 4,000 million hectares, would be suitable for cultivation.<sup>113</sup> A similar estimate was obtained by Stamp, who reached this figure by eliminating from the total land area, the areas under permanent snow or ice; mountain and plateau regions unsuitable for cultivation and arid regions—each estimated to account for one fifth of the total—and then deducting another 10 per cent to allow for poverty of

soils, excessive rainfall and so forth.<sup>114</sup> Baade also estimated that the area under cultivation could be increased to 4,000 million hectares.<sup>115</sup> Clark assessed the potential agricultural area of the world in terms of standard land—that is the type of land found in the humid temperate zones, capable of producing one crop a year or providing substantial grazing opportunities. Taking as the sole criterion climatic conditions, he estimated the potential in equivalents of standard farm land to be near to 7,700 million hectares.<sup>116</sup> Various estimates of the arable land of the world under different assumptions were made by Malin. With existing methods and no capital investments, the arable land could be increased, he asserted, to about 2,700 million hectares. With capital investments for land development, this figure would increase to nearly 5,500 hectares and new methods of cultivation, in combination with substantial investments, would bring the total to as high as 9,300 million hectares.<sup>117</sup> Another estimate was prepared by the United States President's Science Advisory Committee which, on the basis of different soil groups, climates and amounts of precipitation, calculated that the potentially arable land of the world was 7,860 million acres—or about 3,200 million hectares—representing somewhat over 24 per cent of the total land area.<sup>118</sup> While these different estimates concur to the extent that they all indicate the possibilities of increasing the land under cultivation, the wide range of the estimated potentials suggests that such world-wide estimates involve a large margin of uncertainty.

48. According to the available estimates, there is slightly less than 0.4 hectares per person of the world's land under cultivation,<sup>119</sup> while the amount of agricultural land, which includes, besides land under cultivation, also permanent meadows and pastures, is estimated to be around 1.2 hectares per person. These figures compare with about 3.7 hectares of total land per person<sup>120</sup> (see table XII.10). It should be noted, however, that such estimates have various limitations. They involve

<sup>110</sup> United Nations, *Population and Food Supply* (1962), p. 30, table 9; Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1963* (1963), p. 100, table III-1. See also Sen, "The impact of population growth . . ." (1967); United States Department of Agriculture, *Changes in Agriculture in 26 Developing Nations . . .* (1965), pp. 19-21; Schaub, "Agriculture's performance . . ." (1970); United States President's Science Advisory Committee, *The World Food Problem . . .*, vol. 1 (1967), p. 19; Revelle, "Population and food supplies . . ." (1960).

<sup>111</sup> See table XII.11. Also Stamp, *Our Developing World* (1960), p. 42; United Nations, *Population and Food Supply* (1962), p. 34; Brown, *Man, Land and Food . . .* (1963), pp. 17-18. The proportion is somewhat below 10 per cent for the developing regions as a whole and near to 12 per cent in the developed. See also Food and Agriculture Organization of the United Nations, *Provisional Indicative World Plan for Agricultural Development . . .*, vol. 1 (1970), p. 42.

<sup>112</sup> Some writers, however, have argued that already more land than that which is suitable for cultivation is used for that purpose. Pearson and Harper, *The World's Hunger* (1945), p. 18, estimated that only over 1,000 million hectares, or 7 per cent of the total land area, is adapted to food production. See also Vogt, *Road to Survival* (1952), pp. 27-28. Whitaker, "World land resources . . ." (1952) asserted that there were only two acres of cultivated land for each person in the world, and that the extension of this area would present serious handicaps, but that at least two and one-half acres per person would be needed to ensure a satisfactory level of living. Another study considered an estimate of 12 per cent of the land area as suitable for cultivation a realistic one. See Political and Economic Planning, *World Population and Resources* (1959), p. 31.

<sup>118</sup> United States President's Science Advisory Committee, *The World Food Problem*, vol. 2 (1967), pp. 407-469.

<sup>119</sup> Land under cultivation is defined here as to consist of "arable land" and "land under permanent crops". The former includes: land under temporary crops; temporary meadows for mowing or pasture; land under market and kitchen gardens; and land temporarily fallow or lying idle. The latter includes land cultivated with crops which occupy the land for a long period and need not be replanted after each harvest; land under shrubs, fruit trees, nut trees and vines; but it excludes land under trees grown for wood or timber. See Food and Agriculture Organization of the United Nations, *Production Yearbook, 1970*, vol. 24 (1971), p. 700.

<sup>120</sup> For similar data, see United States President's Science Advisory Committee, *The World Food Problem . . .*, vol. 2 (1967), p. 434, table 7-9; McCormack, *The Population Problem* (1970), p. 52, table 3-3; Organisation for Economic Co-operation and Development, *The Food Problem of Developing Countries* (1968), p. 70, table IV.1.

where land is still plentiful—an occurrence considered unlikely under present conditions—the solution to the problem of increasing agricultural production must be found within national boundaries. Finally, as a result of the rapid growth of population, land is likely to become increasingly short in many developing countries and it is unlikely that the extension of crop land alone would be sufficient to cope with the increased demand, which may be expected as a result of demographic trends.<sup>129</sup>

50. Given these various constraints on the expansion of the area under cultivation, as well as the fact that ultimately the quantity of land suitable for agriculture is limited, the importance of raising the productivity of land for increasing agricultural and food production has been nearly universally recognized.<sup>130</sup> Moreover, the available data on recent trends in the productivity of land<sup>131</sup> indicate that the possibilities for raising the output per hectare are substantial in most countries and, in many, exceed the possibilities of raising total production through an increase of agricultural land.

51. Data on yields of individual crops and livestock, as well as estimates of the over-all productivity of land, confirm the existence of large differences between countries. Estimates for some major crops in 1957, compiled by Malin, showed that yields in countries with the highest productivity may be as much as ten times or more those in countries with the lowest yields:<sup>132</sup>

Yields per hectare (hundred kilogrammes)

	Average	High	Low
Wheat ..	10.7	42.7 (Denmark)	3.2 (Burma)
Rye .....	11.1	29.2 (Netherlands)	3.1 (Australia)
Barley ...	12.9	40.6 (Netherlands)	2.3 (Tunisia)
Oats ....	12.4	33.3 (Denmark)	4.1 (Portugal)
Rice ....	18.4	57.4 (Spain)	6.3 (Puerto Rico)

52. More recent estimates suggest that these differences have not decreased significantly since then. Average yields of wheat for the years 1968 to 1970 varied from little over 200 kilogrammes per hectare in Libya,<sup>133</sup> to more

than 4,400 in the Netherlands. The corresponding ranges for the other crops mentioned were: rye, from 390 kilogrammes per hectare in South Africa to 3,800 in Switzerland; barley, from 280 kilogrammes per hectare in Libya to 3,900 in Ireland; oats, from 480 kilogrammes per hectare in South Africa to over 3,900 in the Netherlands; and rice, from 560 kilogrammes per hectare in Mali to 7,000 in Australia.<sup>134</sup> The range in over-all productivity of land may be expected to be greater than that of individual crops, since total productivity also reflects such factors as differences in managerial skills and methods of cultivation, including land rotation, mixed farming, and so forth.<sup>135</sup> Estimates of the productivity per acre in terms of nutrition calories,<sup>136</sup> prepared by Stamp for thirteen countries in the late 1950s, indicated that the standard nutrition units per cultivated acre varied from 0.2 in Australia to 6.5 in Japan, implying that while in Japan each acre could support 6 to 7 persons, in the case of Australia 5 acres would be needed to produce enough calories for one person.<sup>137</sup> In general terms, it has been estimated that the over-all productivity of land in countries with the highest yields may be some 40 times that of countries with the lowest productivity.<sup>138</sup> Indices of over-all productivity for fifty-two countries for a recent period, presented in table XII.11, suggest an even wider range of variation. Productivity per hectare in the three countries with the highest yields is between 8 and 11 times that of Yugoslavia, which being at mid-point was assigned the index 100. Yields per hectare in the latter country are, however, about ten times as high as those in the three countries with the lowest productivity.<sup>139</sup>

53. Output per hectare is usually higher in the more developed as compared with the less developed countries, though this is not true in all cases.<sup>140</sup> The data in table XII.12 show that even though some of the highest yields are found in developing countries, the majority of the twenty-six countries with highest productivity are more developed countries and among the remaining twenty-six countries with low productivity the greater number are developing countries. Other estimates tend to confirm the lower average productivity of land in the developing regions. Estimated grain yields per acre harvested in 1960-1961 were 699 kilogrammes for the developed as compared with 506 kilogrammes for the developing countries.<sup>141</sup> Despite recent increases in

<sup>129</sup> Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1968* (1968), p. 101; Organisation for Economic Co-operation and Development, *The Food Problem of Developing Countries* (1968), pp. 70-71, 107.

<sup>130</sup> Russell, *World Population and World Food Supplies* (1954), p. 64; United Nations, *Population and Food Supply* (1962), p. 38; Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1963* (1963), p. 95; ———, *The State of Food and Agriculture, 1968* (1968), p. 75; Harrar and Wortman, "Expanding food production in hungry nations . . ." (1969); Organisation for Economic Co-operation and Development, *The Food Problem of Developing Countries* (1968), p. 107; United Nations, *Human Fertility and National Development . . .* (1971), p. 19; Christensen, "Problems and policies in the 1970's" (1970); Spengler, "Agricultural development is not enough" (1968).

<sup>131</sup> The productivity of land can be measured either in terms of money values or in terms of physical yields or calories. Output per hectare thus can be increased either through higher yields of existing crops or a shift towards crops with a higher value. See Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1963* (1963), pp. 97-98; also Schaub, "Agriculture's performance . . ." (1970).

yields in the developing countries, they fell relatively further behind the more developed countries, since productivity increased even more rapidly in the latter. It has been estimated that grain yields in 1967 were 1.2 tons per hectare in the developing regions and 2 tons in the developed ones. Compared with the estimates for 1954—0.97 tons in the developing and 1.40 tons in the developed regions—the difference increased in both absolute and relative terms.<sup>142</sup>

54. The interrelations between population, agricultural land, its productivity and the levels and growth of agricultural and food production are complex and have been the source of considerable controversy. As has been discussed in more detail in another chapter,<sup>143</sup> the classical school of economists, under the influence of Malthus' work, held that population would tend to increase with the means of subsistence, causing an increasing pressure on the fixed supply of land, diminishing returns and, eventually, a stagnation of production and the stabilization of population at the subsistence level of living. The experience of the presently developed countries during the last one and a half centuries or so, however, did not bear out these views. As a result of the increasing control over fertility, population growth failed to respond to the increase of the means of subsistence in the manner anticipated by the classical school. In addition, these

writers had underestimated the potential contribution of greater knowledge and technological progress, which made it possible for agricultural production to outpace population growth by a considerable margin. As the threat of subsistence crises in the more developed countries disappeared, the importance assigned to the traditional limits to agricultural production, namely, the fixed supply of land and its diminishing returns, and to the impact of population trends on the capacity to feed a growing population has decreased considerably.<sup>144</sup> Nevertheless, this does not mean that no relation exists between population, on the one hand, and the availability of agricultural land and its productivity, on the other. Especially in the developing countries, where modern technology has not yet penetrated agriculture and where rapid population growth raises the already high agricultural density, the relation between population and agricultural land, as well as the productivity of the land, are fundamental issues.

55. It is usually assumed, as postulated in the classical theory, that a general relation exists between the size and growth of population and the land used for agricultural purposes. Thus, as has been noted before,<sup>145</sup> it is held

<sup>144</sup> For the lessened emphasis placed on land, see, for instance, Schultz, "The declining economic importance ..." (1951); also Kuznets, "Population and economic growth" (1967); Spengler, "The economist and the population question" (1966).

SOURCE: data on land use: Food and Agriculture Organization of the United Nations, *Production Yearbook, 1970*, vol. 24 (1971), table 1; data on density: United Nations, *Demographic Yearbook, 1970* (1971), table 2.

that historically the growth of population has been associated with an increase of the land under cultivation. Likewise, the existence of high population densities is frequently seen to be an indication of limited possibilities to increase further the land under cultivation.<sup>146</sup> Even so, there is only limited evidence of a systematic relation between the density of population and the proportion of total land used for agriculture or under cultivation in different regions and countries. The land used for agriculture as a proportion of the total land area in different regions (see table XII.10) does not appear to be in any way related to the number of total hectares per person as an indicator of population density. However, data referring to the proportion of land under cultivation may be thought to provide some evidence of a relation between density and cultivated area. High percentages of cultivated land are found in such densely populated regions as Europe and the Far East and a low percentage is found in such a sparsely settled region as Oceania. However, China, with a low proportion of cultivated area, does not conform to the pattern of the other high density areas and the association appears also to be weak when the other regions are considered.

56. Data on the percentage of total land under cultivation and on over-all population density for a large number of countries appear to confirm the existence of a general but not necessarily invariable relationship between the two (table XII.12). The proportion of total land under cultivation is generally low in countries where population density is low and high where population density is high. Nevertheless, there are a number of exceptions to this association and, especially when density classes between the two extremes are considered, the association between density and land use, although it appears to exist, is not very clear and systematic. Part of the explanation of a lack of a consistent relation in this regard may be attributed to the crude nature of such a measure as over-all population density. More fundamental, however, are numerous factors which determine land use. Prominent among these are the potential agricultural land and its quality. In addition, such factors as the levels of over-all and agricultural development, the type of agricultural products and systems of land tenure, to name but a few, influence the amount of effective agricultural land.

57. Population growth, it may be argued, will not only tend to have the effect of increasing the land used for agriculture, but may also give rise to a more intensive cultivation by increasing the labour expended on land already in use.<sup>147</sup> It might be expected, therefore, that, as a rule, higher population density would be associated with a higher number of persons per unit of agricultural land. The data for different regions on number of persons per unit of agricultural or cultivated land seem to bear out that land use is not independent from population density. Comparatively high population densities, as shown by the low land area per person, in the Far East, Europe and China are associated with low averages of agricultural and cultivated land per person (table XII.10). Lower average densities in the Near East and Latin America are accompanied by higher averages of agricultural and cultivated land per person. However, variations between regions also convey the impression that, especially in the case of agricultural land, the association is not a systematic one. Data on population density and the number of hectares of cultivated land per person for a large number of countries also show that high population density tends to be accompanied by a more intensive use of land and that the opposite is true in most cases where density is low (see table XII.13). However, although there exists a fairly clear distinction between countries at very different levels of density as far as the number of persons per hectare of cultivated land is concerned, the variation within each of the classes of density is considerable.

58. Population size and growth are thought to affect not only the availability of land and the amount of labour expended on it, but also its productivity, since population density is a factor influencing the intensity with which the land is used. It may be expected, therefore, that countries with high population densities, which they can support only by intensive methods of cultivation, will tend to have a higher productivity of land than less densely settled countries. A comparison of data on hectares of cultivated land per person, as an index of density, and yields for some of the major crops for the different regions of the world, however, does not suggest the

<sup>a</sup> Excluding China.

existence of a clear association between density and the productivity of land (table XII.14). Part of the explanation for the lack of such an association may be that, as has been noted before, the productivity of land, on the whole, is considerably higher in the more developed than in the less developed regions. If the data for each of these two broad groups are considered separately, there are some indications that density and the productivity of land are not independent of each other. Both within the group of developed regions and within that of the developing regions, yields are highest in the most densely populated ones and lowest in those less densely settled.

59. Data on number of persons per hectare of farm land for fifty-two countries classified into four groups in descending order of levels of productivity per hectare indicate that density is not without importance as a factor in the productivity of land (see table XII.15).<sup>148</sup> Most of the countries in the first quartile, that is, the high-

est range of productivity, have a high density and, conversely, all the countries in the upper quartile, that is, the lowest productivity per hectare, have a low population density. Of the thirteen countries with highest yields per hectare, only one had less than two persons per hectare while, in three, population density exceeded 10 persons per hectare. In contrast, each of the thirteen countries with lowest productivity had less than one person per hectare of farm land. Unweighted average densities differed considerably for each of the four levels of productivity; they declined from 5.9 for the first quartile of high productivity countries to 2.0 for the second, 1.2 for the third and 0.34 for the fourth quartile with lowest productivity per hectare.<sup>149</sup> A comparison of the gross output per hectare and food expenditures per hectare in thirty-six countries led to the conclusion that the intensity of cultivation and output per hectare varied positively with the pressure of demand on the land cultivated.<sup>150</sup>

<sup>148</sup> The classification according to productivity was based on index numbers, with Thailand, which was at the mid-point of the range, being 100. The index numbers for the thirteen countries with highest productivity ranged from somewhat less than 200 to 600; for the next group, indices varied between somewhat over 100 to less than 200; for the third group, from about 50 to 100 and, for the

last group, from around 10 to 50. See Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture*, 1963 (1963), figure III-7.

## 2. AGRICULTURAL LABOUR AND ITS PRODUCTIVITY

60. Although agricultural and food production can be increased by means of adding to the area under cultivation or the number of people working the land, or both, such measures by themselves will not provide the solution to the food problem being faced by many developing countries, nor the more fundamental issue of agricultural under-development. Increasing the agricultural land or labour force without considerable investments in land, material capital and human resources and in the absence of technological progress or institutional change will in most cases rule out significant improvements in the prevailing and often inadequate *per capita* levels of food supplies and is bound to result eventually in diminishing returns to both land and labour and in the incapacity to feed a growing population. Ensuring sufficient food supplies and satisfactory levels of nutrition for a growing population can only be attained by raising the productivity of agricultural labour. Increasing output per farm worker, however, is not only a condition for solving the food problem. The increasing levels of income it causes and the more efficient employment it engenders by permitting the transfer of agricultural labour to non-agricultural sectors are essential prerequisites for and basic elements of the process of agricultural and over-all development.

61. The productivity of labour in agriculture is closely associated with the size of the agricultural labour force. Low productivity in agriculture implies not only low levels of income in this sector and an under-utilization of its labour force, manifesting itself frequently in high levels of underemployment, but also signifies that in order to provide the population with sufficient food, a large part of the total working population must be, of necessity, engaged in agricultural production. Thus, as has been noted, in developing countries agriculture may absorb as much as four fifths of the total working population.

The development process makes possible the transfer of workers from agriculture to secondary and tertiary activities, so that in the more developed countries as little as one tenth or less of the labour force is found in agriculture.<sup>151</sup>

62. According to the available data, the share of agricultural workers in the total labour force has been declining at an accelerating rate in the more developed countries. Estimates, cited in other chapters,<sup>152</sup> indicate that the proportion of the working population in agriculture in these countries was around 60 per cent at the beginning of the century and 30 per cent in 1960. Since then this process has continued at an accelerating rate. In absolute terms, the number of agricultural workers for the more developed countries, as a whole, probably did not decrease until the 1920s, but since then up to 1960, the agricultural labour force in these countries, excluding the USSR and Eastern Europe, may have been reduced by some 20 million. In contrast, the proportion of the labour force in agriculture in the developing countries, as a whole, has changed only slightly, although it has been declining in a number of such countries. Tentative estimates for 1900 suggest that at that time only somewhat less than four fifths of the total working population was engaged in agriculture and data for 1960 indicate that this proportion was still 71 per cent. In addition, the absolute size of the agricultural labour force in these countries has been growing at what appears to be an accelerating pace. The estimated increase of some 60 million agricultural workers in the less developed countries between 1950 and 1960 was higher than the estimated growth in the twenty years from 1930 to 1950.

<sup>151</sup> For a general discussion of these aspects, see chapter XIV, section A and chapter IX, section D.

<sup>152</sup> See chapter IX, section D and chapter XIV, sections B and D.

TABLE XII.16. NUMBER AND PERCENTAGE OF LABOUR FORCE IN AGRICULTURE FOR MAJOR AREAS AND REGIONS OF THE WORLD, 1950 AND 1960

Major area and region	1950		1960	
	Agricultural labour force		Agricultural labour force

63. Estimates of the absolute and relative size of the agricultural labour force for the world and major regions are shown in table XII.16. In general, these results illustrate the differences in the importance of the agricultural sector in the more developed and less developed regions and the sharp decline in the percentage share of agriculture in the more developed regions between 1950 and 1960, especially in those regions where the initial share was still high. A much slower evolution is shown for the less developed regions, with the exception of Latin America. Finally, the results show that, except for Oceania,<sup>153</sup> the number of agricultural workers declined in all

<sup>153</sup> The data for Oceania include, apart from Australia and New Zealand, also Melanesia and Polynesia and Micronesia. In the former two developed countries, the agricultural labour force declined in absolute numbers, as it did in the other more developed regions.

of the more developed regions, but increased in all of the developing ones. Rough estimates of the agricultural population and its percentage of the total population are also available for the world and different regions in two recent years (table XII.17). These results, although not directly comparable with the data on labour force in agriculture because of possible differences in economic activity rates in the agricultural and the non-agricultural sectors provide confirmation of the findings suggested by the data on labour force. In addition, they convey some indication of the capacity of the agricultural population to support itself and the non-agricultural segment. Assuming a constant relation between labour force and total population and the number of families, it may be said that in Africa the average agricultural family produced an amount of food-stuff less than one third in excess of its own, possibly inadequate, consumption. In contrast,

in North America the production of one family was enough to support beside itself, between 15 and 16 other families.

64. The measurement of labour productivity in agriculture is not only more complex than that of the productivity of land, but, in addition, various measures may be used to assess it. One way of expressing differences in the productivity of labour is to compare the labour input, in terms of man-hours or man-days, needed to produce a given quantity of an agricultural commodity. According to estimates of the Food and Agriculture Organization of the United Nations, the number of man-hours needed to produce that 100 kilogrammes of wheat varied from about 1 to 2 to as much as 30 to 50 hours in countries at different levels of development. The range was also found to be considerable, for instance, in the case of potatoes, but for some other products, such as sugar beets, cotton and tobacco, the differences between countries at different levels of development were much smaller.<sup>154</sup> An alter-

native method is to measure the productivity of labour in terms of an important indicator of agricultural production. Brown, for example, measured the productivity of agricultural labour in terms of grain output per person of farm population. According to his estimate, the *per capita* product of the farm population in the developed regions in 1960-1961 was about 2,200 kilogrammes, compared with only some 370 kilogrammes in the developing regions. In addition, the corresponding data for the pre-war period—1934 to 1938—indicated that the gap between the two groups of countries had widened. Whereas in the earlier period the output in the developed regions was four times that of the developing regions, by 1960-1961 this ratio had increased to nearly 5.9.<sup>155</sup>

65. Despite the problems involved in their estimation,<sup>156</sup> indices of output per male working in agriculture

<sup>155</sup> Brown, *Man, Land and Food* . . . (1963), pp. 87-88, table 31. For similar figures, see Schaub, "Agriculture's performance . . ." (1970).

<sup>156</sup> Both the estimates of labour input and output are hampered by a lack of data, as well as problems of estimation itself. Statistics on the number of man-hours spent in agricultural production are

<sup>154</sup> Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1963* (1963), pp. 112-113, figure III-9.

(Continued on next page)

for thirty-three countries since the late 1950s have been prepared by the Food and Agriculture Organization of the United Nations (table XII.18).<sup>157</sup> Product per worker in agriculture varies, as may be seen, between wide limits. In New Zealand, the country with highest productivity, the output per worker was some 12 to 15 times that of Italy, which, being at about the mid-point, was given the index of 100. The productivity in the latter country was, during the various periods, between some six to eight times that of the countries with the lowest output per worker. In more general terms, output per male worker in agriculture in New Zealand, Australia and the United States was for the different periods from nearly 70 to 95 times greater than in the countries in the lowest range, India, the Republic of Korea and the Philippines.<sup>158</sup> The data also suggest that since the late 1950s the relative position of the countries with low productivity with respect to the countries of high productivity has not improved, but rather deteriorated.<sup>159</sup>

66. The ranking of countries in table XII.18 also indicates, as might be expected, that the output per worker in agriculture is related to the general level of development. As a rule, the economically more developed countries with relatively high *per capita* income are found in the upper range of the table, whereas economically less developed countries are mostly in the lower range. In more specific terms, levels of productivity in agriculture have been related to two factors, both indicative of levels of development: the *per capita* expenditure on food—as an indicator of demand related to levels of income—and the proportion of the labour force in agriculture. Comparing output per man with *per capita* expenditures on food per male in the agricultural labour force, a close association between the two was found to exist.<sup>160</sup> These findings, apart from confirming the relationship between levels of productivity and agriculture and of development, also provide further evidence of the inverse relationship between agricultural productivity and the share of agricultural workers in the total labour force.

(Footnote 156 continued)

available for only a few countries and even then they are not always comparable. More data are found on the numbers of workers in agriculture, but this constitutes a much less satisfactory measure. In addition, the data often have to be limited to the male labour force because of the incomparability of data on the female labour force. Such a limitation may introduce an additional bias, especially in the less developed countries where the work of unpaid female labour in agriculture may be important. Data on agricultural production, of course, pose another series of problems. See Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1963* (1963), p. 116.

<sup>157</sup> Similar data for an earlier period were published for thirty-six countries in Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1963* (1963), table III-11, p. 117.

<sup>158</sup> On a world-wide basis these ranges may be even wider, since output per worker is probably even lower in some less developed countries for which no data are available.

<sup>159</sup> A similar conclusion was reached by Hayami and Ruttan on the basis of estimates of productivity in 1965 and 1966 for forty-three countries. See Hayami and Ruttan, *Agricultural Development ...* (1971), table 4-2, pp. 71-73.

<sup>160</sup> Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1963* (1963), pp. 117-119, figure III-11. The data used for this analysis referred to twenty-eight countries in the period 1956-1960.

67. The effects of population size and growth on productivity in agriculture have been the subject of wide discussion. This question has received special attention in the context of the problems of so-called "rural overpopulation" and underemployment in agriculture in the densely settled developing countries. According to some writers, as a result of the unfavourable man-land ratio in these countries, productivity in agriculture is very low and may be even zero over a wide range. A considerable controversy exists as to the extent of underemployment in such cases, including the question whether the problem is mainly one of seasonal underemployment, and as to the assumption of zero or negligible productivity of labour. Although those with divergent views recognize that the productivity of labour in many of these countries is low, some question whether it is a result of an excessive pressure of population on agricultural resources and argue that low productivity may be to a large degree the result of other factors, such as lack of capital, institutional factors and so forth.<sup>161</sup> The implications of population growth, as opposed to its size, for agricultural productivity in the less developed countries is generally thought to be unfavourable, except under conditions where land is plentiful and distinct economies of scale would result from a larger population. In general, however, rapid growth of the agricultural population and labour force is thought to be an obstacle to increasing productivity. Although the increase of agricultural population has been accompanied in many countries by an expansion of the area under cultivation, the fact that the latter has not kept pace with population growth suggests that while the number of holdings has grown, their average size, already small in many cases, may have declined.<sup>162</sup> In more general terms, it has been noted that it is much more difficult to increase the output per worker when the ratio between agricultural workers and land is high or when their total number is growing, such as is still the case in most developing countries, than when the size of the agricultural labour force is shrinking, as it is in the developed countries.<sup>163</sup>

68. Although general studies on the subject suggest the existence of a negative association between agricultural density and the productivity of agricultural labour,<sup>164</sup> little is known about the actual relations between the two. Clark in an early study found that production per farm-worker varied inversely with the square root of male workers per thousand hectares of farm land.<sup>165</sup> In a later study a comparison of the number of persons engaged in agriculture per square kilometre of cultivable land with

<sup>161</sup> For a discussion of the literature on underemployment and the productivity of labour in densely populated, developing countries see chapter XIII, sections C and D.

(1970); Hayami and Ruttan, "Agricultural productivity differences ..." (1970).

<sup>164</sup> See chapter XIII, section D.

<sup>165</sup> *Ibid.*

the agricultural production per worker for twenty-six countries led Clark to conclude that there was little relation, if any, between the density of settlement and average agricultural product per head.<sup>166</sup> A comparison of agricultural workers per 100 hectares of agricultural land and output per agricultural worker in twenty-three countries suggested a general, but not completely consistent tendency for product per worker to be higher where the number of workers relative to the agricultural land was lower.<sup>167</sup>

69. From comparisons of the productivity of land and that of labour in forty-three countries, Hayami and Ruttan concluded that the relation between the two varied according to the availability of land. They found that the data revealed three different patterns: (1) high productivity per worker was associated with particularly favourable man-land ratios, including such cases as New Zealand, Australia and the United States; (2) comparatively low productivity per worker was associated with high output per hectare, as exemplified in particular by Japan and Taiwan in Asia; and (3) intermediate levels of productivity of both land and labour, were found in cases where land endowment falls between the two other groups, examples being the Netherlands, Denmark and Belgium.<sup>168</sup>

70. Another factor, which sometimes has been mentioned in connexion with population is the ceiling imposed on agricultural production and productivity and the limited domestic market for farm products in the developing countries.<sup>169</sup>

71. The fact that in many developing countries food production has recently lagged behind demand indicates that this ceiling has not yet been reached. It has also been recognized, however, that the effect on food production and the productivity of labour resulting from the higher demand associated with the growth of the non-agricultural population usually remains small until the stage of development has been reached where the agricultural population starts declining not only in relative, but especially in absolute terms.<sup>170</sup>

### 3. POSSIBILITIES OF INCREASING FOOD SUPPLIES

72. The continued rapid increase of population in the developing countries is a main determinant of the future requirements and demand for food, and the possibilities of increasing food supplies sufficiently are among the major issues faced by these countries. There is a measure of agreement that, even though other sources of food exist and need to be explored, the greater part of the increased

food supply in the immediate future must be provided through the increased production of farm crops and rapid agricultural development.<sup>171</sup> Most of the production needed to meet the increased requirements and demand, it is generally agreed, should take place within the developing countries themselves. Although it is recognized that these countries do not necessarily have to aim at complete self-sufficiency in food production,<sup>172</sup> it has also been pointed out that they cannot depend for the solution of their food problem on foreign trade or aid, but that substantial and rapid increases in domestic food production are essential.<sup>173</sup>

73. Virtually all authors agree that the potential for large increases in agricultural and food production exist,<sup>174</sup> but that the problem is that of the application of the necessary technology and the creation of the social and institutional conditions conducive to rapid agricultural development.<sup>175</sup> The important role of social, cultural and institutional factors in traditional agriculture is generally recognized,<sup>176</sup> but substantial differences of opinion remain as to what extent such factors as social organization and institutions, family systems and individual attitudes and motivations constitute an obstacle to agricultural development. According to one view, traditions will only change slowly and are likely to hold back progress. This opinion, however, is contested by others, who argue that given sufficient opportunities and incentives, the farmers in the developing countries will readily adopt modern methods.<sup>177</sup>

<sup>171</sup> United Nations, *Human Fertility and National Development* . . . (1971), p. 19; United States President's Science Advisory Committee, *The World Food Problem* . . . , vol. 1 (1967); Kristensen, "The approaches and findings of economists" (1967).

<sup>172</sup> However, in many developing countries, special emphasis has been given to a greater degree of self-reliance on food. See Food and Agriculture Organization of the United Nations, *The State of Food and Agriculture, 1971* (1971), pp. 3, 10; ———, *The State of Food and Agriculture, 1970* (1970), pp. 155, 160-162; United Nations, Economic Commission for Asia and the Far East, *Economic Survey of Asia and the Far East, 1969* (1970), pp. 22-24; United Nations, *World Economic Survey, 1969-1970* (1971), pp. 118-122.

74. Certain organizational and institutional changes are considered essential for agricultural progress in the developing countries. In many of these countries the system of land tenure is seen as a major obstacle to raising productivity. Small and fragmented holdings may limit severely the opportunities and profitability of introducing new techniques and unsatisfactory land tenure relationships may negatively affect producers' incentives and mobility and create excessive income inequalities.<sup>178</sup> Rapid population growth may increase these problems and, especially in the densely settled areas, give rise to a demand for such reforms.<sup>179</sup> The importance of education and training for farmers and the provision of efficient extensive services have been stressed as a means of creating the incentives for taking advantage of existing technological possibilities.<sup>180</sup> Other organizational and institutional changes often mentioned include the creation of credit facilities in order to provide the substantial funds required for the application of improved technology; adequate channels of marketing, transport and storage so as to make possible the efficient supply of the new inputs, such as fertilizers and pesticides, which form part of the new technology, as well as the sale of the increased output; the use of price subsidies and price stabilization measures so as to strengthen the farmer's incentives and to assure farmers' income and so forth.<sup>181</sup> In a broad sense, as has been noted before,<sup>182</sup> agricultural development depends to a large extent on over-all economic and social development and is unlikely to succeed unless it is part of the general process of growth and transformation.

75. Although on a global scale and in many individual countries considerable possibilities remain for increasing the land under cultivation<sup>183</sup> and organized settlement schemes have been undertaken in some areas,<sup>184</sup> it is

<sup>178</sup> Food and Agriculture Organization of the United Nations, *Provisional Indicative World Plan for Agricultural Development* . . . , vol. 2 (1970), chap. 11; ———, *The State of Food and Agriculture, 1968* (1968), pp. 100-101; United States Department of Agriculture, *Changes in Agriculture in 26 Developing Nations* . . . <sup>183</sup> See the discussion earlier in this section.

<sup>184</sup> For a general discussion of such schemes see Lewis, "Thoughts on land settlement" (1954); Mellor, *The Economics of Agricultural Development* (1966), pp. 185 ff.; Bridger and de Soissons, *Famine in Retreat?* . . . (1970), pp. 92-95. For aspects related to population growth and pressure see Omaboe, "The population pressure . . ." (1967).

generally agreed that increases in agricultural and food production will depend mainly on increasing the productivity of the land already under cultivation. A great number of measures can be taken to raise the productivity of land, including: the greater use of machinery and capital equipment,<sup>185</sup> the increase in irrigated area and the better use of water; product diversification and crop rotation as well as the substitution of direct food production for livestock production;<sup>186</sup> a greater use of fertilizers and soil conservation practices; more protection against pests and diseases; the use of improved seeds; improvements in livestock production and forestry and farm management in general.<sup>187</sup>

76. Special attention has been given in recent years to the results of the application of the new technology in the cultivation of cereals. The availability and spread of the high-yielding varieties of rice, wheat and maize have increased production of the crops greatly in a number of countries and created the expectation of a "green revolution".<sup>188</sup> While these developments may be the beginning of a reversal of the unsatisfactory trends in food production in the developing countries and of the increasing productivity gap between them and the more developed countries, such a process will not be automatic or without problems. For the "green revolution" to succeed it will be necessary not only that the gains so far made be maintained but also that the technical breakthrough—confined largely to rice and wheat and mainly to certain areas or countries, especially in Asia—be extended to other developing countries and other crops, and to farm products in general through further agricultural research and development.<sup>189</sup> Moreover, the dissemination of the new varieties depends on certain conditions, which are not unlike those required for agricultural development along more traditional lines. In the case of rice, for

<sup>185</sup> As has been pointed out by a number of writers, there are limitations both of an economic and social nature to the degree of mechanization, such as the effect it may have on displacement of labour. Christensen, "Technologies of increasing food production" (1952).

<sup>186</sup> The importance of feed consumed by livestock as part of total food production has been stressed by various writers. See especially Borgstrom, *The Hungry Planet* . . . (1965), chap. 1.

instance, it was held that the success of high-yielding varieties was influenced by such factors as water control; efficiency of plant protection or resistance to pests and diseases; the yield advantage over existing varieties; the quality of new rice grains; the availability of complementary inputs; efficiency of farm management and so forth.<sup>190</sup> Finally, it has been noted that the success achieved in increasing the output of the cereals concerned creates its own problems, including the difficulties in the disposal of surpluses that have been created as a result of the rapid increase of production, the price and supply relationships; the greater concentration in holdings which may be the result of possible economies of scale with respect to the new varieties and the potential negative effect their cultivation may have on employment.<sup>191</sup> While the introduction of the high-yielding varieties is generally seen as a potential breakthrough in agricultural production, there is also a measure of agreement that for the latter to happen, continued efforts will be needed to remove the existing constraints for a wider application and to remedy the possible less favourable consequences which such a wider use might create.

77. Although agriculture is by far the main source of food supply and likely to remain so for a long period, increasing attention has been given in recent times to alternative possibilities of obtaining food, especially by using the available fishery resources and through the development of non-conventional food resources. It is estimated that while at present only between 1 and 2 per cent of the total food supply consists of fish,<sup>192</sup> fishery resources in oceans and fresh waters are such that they could provide a substantially greater proportion. Even so, there are limits to the catch that can be obtained by present-day methods: it has been estimated that the potential catch of marine fish could increase between 2 and 3 times over the 1965 level.<sup>193</sup> In addition, it is held that there are considerable opportunities for increasing food supplies through unconventional methods. Such methods could include the production of artificial food, the use of marine plankton and the cultivation of algae; the use of micro-organisms as converters of food; the extraction of

proteins from non-food materials (such as leaves) and so forth.<sup>194</sup>

78. In general, it is held that the problem of increasing food supply and agricultural production is not one of a lack of technological knowledge, but of the application of such technologies on a sufficient scale and where needed.<sup>195</sup> Under these circumstances, effective policies to mobilize capital and human resources, to implement the necessary organizational and institutional changes, together with efforts to reduce excessive rates of population growth are essential prerequisites and conditions for ensuring adequate food supplies, nutrition and levels of living of the population.

#### D. Outlook and projections

79. The outlook for feeding an increasing population has been a subject of speculation for a long time,<sup>196</sup> but has received special attention in recent decades in response to both the rapid growth of population and the desire for development and aspirations for higher levels of consumption. Since an increase in food requirements and demand—not necessarily accompanied by a proportionate increase in food production—is among the major implications of population growth, one of the main causes for concern over demographic trends in the developing countries stems from doubts about their ability to produce sufficient food to keep pace with rising population and economic demand.

80. The assessment of the possibilities of feeding a growing population in the future involves various elements. Basically, it consists of a comparison, by means of projections, of requirements of and demand for food, on the one hand, with the production of food, on the other. Projection studies stress the differences between requirements and demand: projections of requirements set out what food supplies should be to feed a growing population at the desirable nutritional standards, while those of effective demand for food attempt to predict how much food is likely to be asked for under the influence of changes in levels of income and population. However, although "effective demand" or market demand projections do not explicitly take into account nutritional requirements and, conversely, projections of nutritional requirements make no explicit allowance for consumers' preferences, the two are not completely unrelated.<sup>197</sup>

<sup>190</sup> Barker, "Economic aspects of high-yielding varieties ..." <sup>194</sup> Pirie, "Future sources of food supply ..." (1962) and his *Food Resources. Conventional and Novel* (1969); Organisation for Economic Co-operation and Development, *The Food Problem of Developing Countries* (1968), pp. 86-88; Russell, *World Population and World Food Supplies* (1954), pp. 498-501.

<sup>195</sup> Taeuber, "Demographic aspects of agricultural development ..." (1967).

<sup>196</sup> Among the first to speculate about such possibilities was, of course, Malthus.

<sup>197</sup> Thus, demand projections generally imply that as incomes rise the consumer will not only buy more but will also change the patterns of his diet in ways that generally improve its nutritional quality. Likewise, in projections of requirements, translated into requirements for different quantities of food, care is taken to ensure that suggested changes in food consumption do not show a radical change and will cost the least to the consumer and that they are generally feasible from the points of view of the economy and production. Food and Agriculture Organization of the United Nations, *Third*

(Continued on next page)

## 1. PROJECTIONS OF REQUIREMENTS

81. Fundamentally, projections of food requirements involve the formulation of food or nutritional targets or standards for *per capita* consumption and estimates of expected future population. As part of its third world food survey, the Food and Agriculture Organization of the United Nations established international nutritional and food supply targets, especially with a view to reducing the extent of undernutrition and malnutrition in the developing countries, and derived total food requirements by means of population projections.<sup>198</sup> Targets aimed at ensuring the quantitative adequacy of the diet were expressed in terms of *per capita* daily calorie requirements, while targets for improving the nutritional quality of the food included *per capita* daily requirements of total and animal proteins—including the ratio between the two—and the percentage of total calories derived from proteins. Targets for principal food groups (cereals, starchy roots, sugar, meat, eggs etc.) were computed, taking into account nutritional targets and certain other conditions such as the cost of food to the consumer.<sup>199</sup>

82. Short-term targets for calories, based on physiological requirements and making allowance for different consumption levels of different social strata and of different family members, were set at 2,550 calories daily per head world-wide, and at 2,350 calories for the "low calorie" or developing countries. The long-term targets were increased by 50 to 100 calories to allow for increases in height and body weight of adults, resulting in a world-wide requirement of 2,600 calories per person per day and 2,450 in the low-calorie countries. Short-term total protein targets for the world were set at 75 grammes daily per person and 69 for the low-calorie countries. The corresponding animal protein requirements were 23 and 15 grammes per head daily, respectively. Long-term targets were 79 grammes of total protein for the world and 74 for the low-calorie countries and animal proteins of 28 and 21 grammes per person, respectively.<sup>200</sup>

83. The expected growth in population for the target dates<sup>201</sup> indicated that world food supplies would need to be increased by 36 per cent between 1958 and 1975 and by 123 per cent by the year 2000, merely to maintain

the existing, unsatisfactory levels of nutrition. If improvements in the diet, as formulated in the nutritional targets, were to be brought about, food supplies would have to expand 50 per cent between 1958 and 1975 and 175 per cent between the base year and 2000. In the low-calorie countries, with population increasing much more rapidly than in the world as a whole, or in the high-calorie countries, the growth in population alone would require increases in food supplies of 41 per cent between 1958 and 1975 and of 150 per cent by the year 2000. Attainment of the nutritional requirements set for these countries would raise total food needs in 1975 by 79 per cent and in 2000 by 293 per cent. For specific food groups the fulfilment of targets would mean, in most cases, even higher increases. In the case of animal products, for instance, the corresponding percentage increases would be 120 and 485 per cent for 1975 and 2000, respectively.<sup>202</sup>

84. Using a similar method, but more recent population projections with the base year 1965, Sen derived estimates of food requirements for 1985 and 2000.<sup>203</sup> The projected world population implied that food supplies would have to be raised by 34 per cent between 1965 and 1980 and by 97 per cent between 1965 and 2000, implying for both periods rates of growth of 2.0 per cent annually. For the developing regions, the percentage increase in population and thus the total requirements needed to prevent a decline in the existing levels of nutrition would be 41 per cent between 1965 and 1980 and nearly 120 per cent by the year 2000, implying growth rates of about 2.2 and 2.3 per cent annually. If nutritional targets are to be met, however, food requirements would be substantially higher, as shown in table XII.19. In order to remove existing deficiencies in diet, according to these estimates, *per capita* total food supplies would have to be increased by one quarter and food of animal origin by nearly one half between 1965 and 1980. Given the projected population estimates, this would mean that total food supplies would have to expand by three quarters and animal foods would have to double. The achievements of these targets would require that total food supplies in the developing regions would have to be increased at an annual rate of 3.8 per cent, and animal food supplies at 5.1 per cent. Projections beyond 1980 to the end of the century show some decline in the annual growth rates of food requirements in nearly all developing regions.

85. Table XII.19 also shows that there is considerable variation among the different developing regions in the growth rates of *per capita* food requirements. This results from variations in the present levels of *per capita* consumption in these regions and the fact that attainment of nutritional targets calls for faster growth rates in those areas where nutritional deficiencies are greatest. Thus, *per capita* food supplies in the Far East would have to increase by 1.7 per cent annually between 1965 and 1980, compared to only 0.7 per cent in Latin America. However, when total food supplies are considered, the differences

SOURCE: Sen, "The impact of population growth on food supplies" (1967).

are much smaller, as the population is projected to increase more slowly in those regions where the increase in *per capita* food requirements is greatest.

86. Calculations of long-term needs for food supplies have also been prepared by the Organisation for Economic Co-operation and Development. Total requirements for the year 2050 were determined on the basis of population projections and assumptions on calorie and animal protein requirements (taking into account the prevailing levels of consumption in the most advanced countries and the effects of new techniques in protein production). According to these calculations, primary calories—that is food and feed crops—would have to multiply about fivefold for the world between 1960 and 2050, and for the less developed countries some eight to nine times. In the developed countries, where increases in consumption were assumed to be much slower, requirements would little more than double.<sup>204</sup>

87. The role of population growth in future food requirements is substantial. As seen above, the increase in population accounts for about half of the total increase in short-term and long-term food requirements for the developing regions, according to estimates in the third world food survey. Sen's estimates, based on revised population projections, show an even higher share of total increase in food requirements in the developing regions attributable to the increase in population. The long-term projections prepared by the Organisation for Economic Co-operation and Development show, in the case of the developing regions, an eight-to-ninefold increase in requirements, while the population was expected to multiply 4.5 times. In the developed regions, where only small further improvements in *per capita* requirements were considered necessary, a population increase of somewhat over 100 per cent (to the year 2050) was accompanied by an increase in total consumption of 130 per cent.

<sup>204</sup> Organisation for Economic Co-operation and Development, *The Food Problem of Developing Countries* (1968), pp. 32-34, table I.4.

88. The effect of decreases in population growth on future food requirements can be estimated from another study. On the basis of two different assumptions of future fertility levels, implying annual population growth rates of 2.1 and 1.7 per cent, respectively, between 1965 and 1985, total calorie requirements were estimated to increase 52 per cent for the high-fertility variant and 42 per cent for the low-fertility variant.<sup>205</sup>

## 2. PROJECTIONS OF DEMAND

89. Projections of effective demand are, as a rule, based on trends in population and income. Although, as noted above, various population characteristics may affect demand,<sup>206</sup> the size and growth of population are generally considered to be by far the most important and are, therefore, generally singled out for purposes of projections. In the case of income, however, allowance must be made not only for its growth but also for the fact that the demand for food varies with the levels of income, as reflected in the income elasticity of demand. At different levels of income, changes in the latter may lead to a different proportional increase in the demand for food.<sup>207</sup>

90. Various recent projections of the Food and Agriculture Organization of the United Nations have included projections of demand for food.<sup>208</sup> One published in 1967<sup>209</sup> was based on food balance sheets, initially prepared for the period 1961 to 1963, showing *per capita* consumption of all food items in the diet. On the basis

<sup>205</sup> United States President's Science Advisory Committee, *The World Food Problem* . . . , vol. 2 (1967), pp. 27, 49.

<sup>206</sup> See section D. The factors discussed there include, besides population growth, its sex and age composition, and the rural-urban distribution of population.

<sup>207</sup> See section B of this chapter.

SOURCE: Food and Agriculture Organization of the United Nations, *Agricultural Commodities—Projections* ..., vol. 1 (1967), p. 34.

Note: countries included in each region are listed in Food and Agriculture Organization of the United Nations, *Agricultural Commodities—*

*Projections* ..., vol. 2 (1967), statistical appendix, tables 1.1 and 1.2, pp. 1-4, 6-9.

<sup>a</sup> The remainder is due to the income effect.

of the quantities of food consumed in the base period, the *per capita* demand for food was projected, assuming constant prices and taking into account the income elasticities of demand. Income elasticities and appropriate demand functions were selected on the basis of the analysis of historical data, results of food consumption surveys and intercountry comparisons. *Per capita* projections were multiplied by the projected population in 1975 and 1985 to obtain national totals of food demands and these results were then aggregated by commodities and commodity groups to obtain regional and world totals.<sup>210</sup>

91. The annual growth rates of demand for food implied under different variants of these projections are shown in table XII.20. The variants presented are based on the United Nations medium population projections and two different assumptions regarding the future growth of gross domestic product: a lower rate broadly conforming to recent trends and a higher rate based on targets formulated in national plans or announced otherwise.<sup>211</sup> According to these projections, world demand for food was estimated to increase at an annual rate of 2.3 per cent under the low gross domestic product assumption and 2.7 per cent under the high variant. These rates remained unchanged during the two decades of the projection period. For the developing regions food

demand was projected to increase at a rate about twice as fast or more than in the developed regions. For the former regions, under the low gross domestic product assumption, the annual growth rate in demand was 3.0-3.1 per cent, as compared to 1.5-1.6 per cent for the more developed regions. The lowest projected growth rates for food demand were in Western Europe and the highest in the Near East.

92. As part of these projections, estimates were also obtained of the levels of expected future calorie consumption and their relation to requirements. For most of the developed regions, where consumption generally exceeded requirements in the base period, consumption was expected to rise only slightly under all variants. More substantial increases were projected for Japan and Southern Europe, where initial calorie consumption was also relatively low. In all of the major developing regions calorie intake was estimated to be below needs in 1962, but was projected to exceed requirements in all cases by 1975, if only by a small margin under the low gross domestic product (GDP) assumption. Substantial improvements in calorie consumption were foreseen in all these regions by 1985 under the assumption of high GDP growth.<sup>212</sup>

93. Projections of the future demand for food with special reference to the developing countries were prepared more recently as part of a study of the food supply and agricultural development problems faced by these

<sup>210</sup> *Ibid.* On the methodological aspects of the study see also Goreux, "Prospects for agricultural ..." (1969).

<sup>211</sup> The published projections contained two additional variants for the 1975-1985 period, based on the United Nations low population projections, combined with the two assumptions on growth of domestic product.

<sup>212</sup> See Food and Agriculture Organization of the United Nations, *Agricultural Commodities—Projections* ..., vol. 1 (1967), table 7 p. 36.

countries.<sup>213</sup> According to these projections, total food demand in the developing countries would increase by 142 per cent between 1962 and 1985, with percentage increases amounting to about 120 per cent in Latin America and in Africa south of the Sahara, over 140 per cent in the Near East and north-west Africa, and more than 150 per cent in Asia and the Far East.<sup>214</sup>

94. The most recent of the demand projections prepared by the Food and Agriculture Organization of the United Nations<sup>215</sup> followed basically the same methodology adopted in the earlier studies. For high-income countries, including Eastern Europe and the USSR, only one assumption on growth of domestic product was made, reflecting for the most part recent trends. Two assumptions on the future growth of gross domestic product, based on recent trends and the targets of the Second United Nations Development Decade, respectively, were used for the developing countries and the Asian centrally planned economies.<sup>216</sup> One population projection, based on the medium variant of the United Nations projections as assessed in 1968, was adopted.

95. The projected demand for 1980, based on the assumption that past trends in the growth of gross domestic product would continue, implied annual growth rates of 2.5 per cent for the world, 1.7 per cent for the high-income countries and 3.6 and 3.0 per cent for the developing countries and the centrally planned economies of Asia, respectively.<sup>217</sup> In *per capita* terms, the increase in the demand for food was similar in different regions—with a percentage rise of 7.9 per cent for the world,<sup>218</sup> 7.2 for the high-income countries and 8.2 per cent for the developing countries. Under the high assumption of growth of gross domestic product, the *per capita* demand would expand 8.9 per cent in the high-income countries and 12.8 per cent in the developing countries.<sup>219</sup> Estimates were also prepared of the demand for calories and proteins expected in 1980 and its relation with requirements. The calorie intake per head for the world as a whole was expected to exceed requirements by 5 per cent. The excess of calorie intake over requirements would be more than 20 per cent in the high-income countries, including Eastern Europe and the USSR, but barely 1 per cent in the developing countries. In the Asian

centrally planned economies, calorie consumption was expected to fall 7 per cent short of requirements. The demand for total proteins by 1980 was expected to surpass the recently proposed requirements—which were greatly reduced in comparison with earlier estimates—by a considerable margin both in the more developed and less developed regions.<sup>220</sup>

96. A relatively simple method was used by the Organisation for Economic Co-operation and Development for projecting the future demand for food, in conjunction with projections of production, for the developing countries in the period 1962 to 1985. Total food demand was projected on the basis of one assumption about future population growth, two assumptions of growth of gross domestic product and income available for consumption, and estimates of income elasticity for demand corresponding to each of the income assumptions. According to the low-income estimate, the total demand for food in the developing countries would increase by 3.25 per cent annually. Under the high-income assumption, the annual growth rate would be 3.40 per cent.<sup>221</sup>

97. According to the available projections, the effect of population growth on the increase in the demand for food is considerably greater than the income effect in nearly all regions. Data on the percentage shares of increase in food demand due to population growth, given in table XII.20, show that population growth accounts for the larger share of the projected demand in both developed and developing regions, with the percentages being, on the whole, higher for the latter group of countries. Despite significant expected increases in income and high-income elasticities of demand in these countries, the demographic factor is predominant owing to the rapid rate of population growth. In the economically more advanced regions, the rate of population growth is much lower, but so is the income elasticity of demand. Even under the high-income assumptions for the developed countries, the effect of population growth outranks the income effect for this group as a whole. Of the different subregions, only Western Europe and Japan show lower or about equal shares for population as compared with income in the different variants.

98. The importance of the population factor in estimating the future demand for food in the developing regions is confirmed by the projections for the Provisional Indicative World Plan for Agricultural Development. Of the expected total increase in food demand between 1962 and 1985, more than 70 per cent would be due to population growth compared with less than 30 per cent resulting from the income effect. Among the different regions, population growth accounted for the largest share of total demand in Latin America (88 per cent) as a result of the high rate of population growth and relatively low elasticity of demand for food in that region. In Africa south of the Sahara, north-west Africa and the

<sup>213</sup> Food and Agriculture Organization of the United Nations, *Provisional Indicative World Plan for Agricultural Development* (1970). See also ———, *Provisional Indicative World Plan for Agricultural Development. Summary and Main Conclusions* (1970).

<sup>214</sup> Food and Agriculture Organization of the United Nations, *Provisional Indicative World Plan for Agricultural Development* . . . , vol. 1 (1970), table 2, p. 15.

<sup>215</sup> Food and Agriculture Organization of the United Nations, *Agricultural Commodity Projections* . . . , vol. 1 (1971). Although these are the most recent demand projections published by the Food and Agriculture Organization of the United Nations, the 1967 projections are used for the most part in this chapter because of their greater regional detail and longer projection period.

<sup>216</sup> Most of the projections used and the results published were based on the low assumption of growth of gross domestic product.

Near East, the corresponding proportion was about three quarters, and in the Far East about two thirds.<sup>222</sup>

### 3. PROJECTIONS OF PRODUCTION AND THE RECONCILIATION OF DEMAND AND SUPPLY

99. The main interest in estimating future food requirements and demand lies in their relation to the expected levels of supplies. Although the latter include both home-produced food as well as the balance of imports and exports, projections of production serve to determine the capacity of domestic production to satisfy requirements or demand as well as to indicate the possible need for imports. Production projections are especially relevant in view of the food problem of the developing countries associated with rapid population growth. By revealing possible imbalances, they make it possible to indicate the direction of economic changes and policy measures necessary to adjust supply and demand.

<sup>222</sup> Food and Agriculture Organization of the United Nations, *Provisional Indicative World Plan for Agricultural Development* . . . , vol. 1 (1970).

100. The projection of production is recognized to be a much more difficult task than that of demand.<sup>223</sup> The relationships between the productivity and output of agriculture, on the one hand, and its inputs—particularly land, labour and capital—are complex. Apart from these factors, many other ones—technological progress and changes in agricultural policies, to name but two—may considerably alter the volume and growth of production. However, in spite of their limitations, projections of production in conjunction with those of demand are, as noted, helpful in providing a basis for the understanding of the food problem, particularly that facing the developing countries.

101. Although it is generally accepted that the problem of increasing food supplies and output will depend mainly on raising agricultural productivity and that labour is an important factor in this regard, in practice most production projections do not directly take into account the effects on agricultural production of the population factor, operating through its effect on the

Note: countries included in each region are listed in Food and Agriculture Organization of the United Nations, *Agricultural Commodities—Projections* . . . , vol. 2 (1967), statistical appendix, tables 1.1 and 1.2, pp. 1-4, 6-9.

\* Computed from three-year averages for 1957-1959 and 1962-1964.

labour force. The effects of population and labour force growth are usually treated implicitly through assumptions concerning the rate of increase in the productivity of agricultural labour. Sukhatme and Schulte have noted the difficulties in assessing the possible effects of population on food production in areas where a large proportion of the population is dependent on agriculture.<sup>224</sup>

102. Several projections of food production on a world-wide scale have been prepared by the Food and Agriculture Organization of the United Nations. Past trends and projections of food production and corresponding projections of demand, published in 1967, are presented in table XII.21. The data suggest that, for the world as a whole, production trends are expected to be capable of meeting the growing demand, since the rates of increase of projected production exactly match those of projected demand during the period 1962-1975. World-wide projections, however, conceal imbalances in demand and production between the more developed and less developed regions. Under the low-income assumption, demand was expected to outpace production by a substantial margin in the developing regions, while the relationship between demand and production was the reverse in the developed regions. The high-income assumption implied a great deal less disparity between demand and production, although even on this basis, production was not expected to quite match demand in the developing regions, while it would slightly exceed demand in the developed regions. The gap between demand and production varied considerably within the group of developing regions. It was especially large in the Near East under the low-income assumption, but even under the high-income assumption it was substantial both in the Near East and Far East. Among the more developed regions, a projected large excess of production over demand is seen for Northern Europe, while considerable, though smaller, production excesses also appear for North America, Western Europe and Oceania.

103. Recent projections published in 1971 suggested a somewhat more favourable outlook for the developing regions. According to these estimates, agricultural production in the developing market economies was expected to grow at an annual rate of 3.3 per cent between 1970 and 1980, and at a *per capita* rate of 0.6 per cent. In the high-income countries the corresponding projected rates were 2.1 and 1.1, respectively.<sup>225</sup>

<sup>224</sup> Sukhatme and Schulte, "Forecasts of nutritional requirements . . ." (1967).

<sup>225</sup> Food and Agriculture Organization of the United Nations, *Agricultural Commodity Projections . . .*, vol. 1 (1971), table 1, chap. 1, p. 13.

104. Various comparisons have been made of growth rates in production and demand and their reconciliation, particularly for the developing countries. According to the Food and Agriculture Organization of the United Nations, production in the developing countries would have to increase at an annual rate of 4.3 per cent between 1967 and 1985, compared with an actual average rate of about 2.7 per cent between 1956 and 1966 in order to meet an increased rate of demand of 3.9 per cent between 1962-1985, since production had already remained behind demand for the period 1962 to 1967.<sup>226</sup> According to a study by the Organisation of Economic Co-operation and Development, total food demand was expected to increase, under the high-income assumption, by 3.4 per cent compared with a rate of growth of food production of 3.1 per cent. Under the low-income assumption, the gap would be wider, with total food demand increasing at a rate of 3.25 per cent annually compared with 2.60 per cent for production.<sup>227</sup>

105. In general, comparisons between the demand for and the production of food suggest that, in the developing countries, where two thirds of the world population lives, demand, no matter how it is measured, tends to outpace production. The role of population in this regard is fundamental. Whereas population growth increases requirements for food and, as has been shown, is also by far the main factor in the growth of the demand for food, there is no such direct relation between population and the growth of production. Efforts to narrow the gap between demand and supply must either be directed towards increasing food production to meet demand or else limiting demand so as to reduce it to a level consistent with supplies. The first approach stresses agricultural development in the developing countries as the only solution to their food problem. The second approach, given the importance of the population factor in determining demand, points to the need for stabilizing population growth, the implications of which have been widely studied. Most demographers and economists are of the opinion, however, that the solution to the food problem in the developing countries lies in the combination of efforts to promote agricultural development while simultaneously reducing population growth to a more manageable rate.<sup>228</sup> Even so, in view of the urgency of the food situation in these countries, international trade and aid are seen as essential elements in the short run for the long-term solution to the problem.

## Chapter XIII

### DEMOGRAPHIC ASPECTS OF SAVINGS, INVESTMENT, EMPLOYMENT AND PRODUCTIVITY

1. Various factors account for the growing interest during recent years in the demographic aspects of economic growth. At the basis of this trend is the widespread preoccupation, especially in the economically less advanced countries, with the problems of economic progress and development. But an important additional element in this evolution was the emergence in these countries of new demographic trends during the past few decades when, as a result of rapidly decreasing mortality and stable, high levels of fertility, an upsurge in population growth, with wide economic ramifications, occurred. Both these factors, together with the better understanding of the processes of economic growth and demographic change, have contributed much to an increased knowledge of the demographic-economic relationship. Nevertheless, this knowledge is far from complete and substantial gaps still persist.

2. This chapter and the following one contain a review of the existing literature on the demographic aspects of economic growth. The present chapter is concerned with the general nature of these relationships and considers, in particular, the influence of population size, composition and distribution, as well as trends and components of population growth on what are among the main direct determinants of economic growth: savings and investment, employment and productivity. Demographic aspects of economic growth in modern times is the subject of the next chapter.

3. Economic growth, in the sense of a sustained increase in national product or income in the aggregate or per head, may be considered to depend primarily upon the nation's resources, the efficiency with which they are used and the institutional framework within which the economy operates.<sup>1</sup> More specifically the output or

product of an economy, given its institutional framework,<sup>2</sup> can be seen as a function of its volume of human, natural and capital resources and their levels of productivity.<sup>3</sup>

4. Population is only one of the many variables which affect the factors of production and, through them, the levels and trends of total and *per capita* income and differences of opinion exist as to the relative importance of the demographic, as compared with other factors. According to some writers, demographic factors have only a limited bearing upon economic growth, while others assert that these factors exert a considerable and, in some cases, even a decisive influence on economic progress. One major reason for a less than complete understanding of these relationships is the lack of adequate data and information. The elucidation of the pertinent relationships is further hampered by the limitations of the analytical framework. It has been pointed out that changes in one factor, such as savings, induced by demographic factors will in turn have effects on the volume, composition and distribution of output. These latter changes will again influence savings in subsequent periods and so forth. Any attempt to take into account these induced effects would necessitate the construction of a comprehensive and fully integrated model of the economy, reflecting not only its existing structure but also its dynamics.<sup>4</sup>

#### A. Demographic aspects of savings

5. Savings and investment, together with financing, are the three stages of capital formation which may be distinguished.<sup>5</sup> Saving may be described as the activity

<sup>1</sup> Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 23-46; Adelman, *Theories of Economic Growth and Development* (1961), pp. 8-24; Peterson, *Income, Employment and Economic Growth* (1962), p. 459; Gill, *Economic Development: Past and Present* (1964), pp. 3-22; Meade, *A Neo-classical Theory of Economic Growth* (1964), pp. 8-18; Bruton, *Principles of Development Economics* (1965), pp. 11-20. This approach to the problem of economic growth is not the only one, nor is it without its limitations. Attempts to explain economic growth include, at the one extreme, those approaches where one specific factor, for instance capital formation, is singled out as the moving force of the economy and, at the other extreme, those which involve a compilation of an as nearly complete as possible list of factors relevant to economic growth, including in addition to the direct determinants also indirect causes or conditions of growth. For listings of the many factors which may be involved in economic growth, see Spengler, "Theories of socio-economic growth" (1949); and his "Economic factors in the development ..." (1951). See also Rostow, *The Process of Economic Growth* (1960), chaps. 1 and 3.

<sup>2</sup> On the importance of social, cultural and political institutions for economic growth, in this context, see: Williamson, "Introduction" (1954), pp. 3-21; Kristensen *et al.*, *The Economic World Balance* (1960), pp. 37-38, 49-52; Rostow, *The Process of Economic Growth* (1960), pp. 70-72; Adelman, *Theories of Economic Growth and Development* (1961), pp. 8-24; Gill, *Economic Development: Past and Present* (1964), pp. 19-20. For an attempt to explore some of the relationships between population and non-economic determinants of economic growth, particularly between population growth and structure and qualitative characteristics of the labour force, see Leibenstein, "The impact of population growth ..." (1967).

<sup>3</sup> The specific relationships between population and natural resources are discussed in chapter XI. The demographic aspects of the size, composition and dynamics of the labour force are dealt with in chapter IX.

<sup>4</sup> Faaland, "Demographic aspects of savings ..." (1966), pp. 297-303.

<sup>5</sup> Friend, "The concept and measurement of savings" (1953); National Bureau of Economic Research, *Capital Formation and* (Continued on next page)

by which claims to production which could be exercised in favour of current consumption are not used to that end and so become available for other purposes. Investment is then the activity by which resources are actually committed to the production of capital goods. Financing is the step linking these two other phases of capital formation. Nevertheless, this distinction between the three elements of capital formation is generally relevant only when each of them constitutes a separate act arrived at by different decision-makers. In economies where the forces of the market are the main determinants of supply and demand,<sup>6</sup> savings by individuals or households will mostly satisfy these conditions as opposed to savings in the corporate or public sector where, as a rule, savings and investment decisions coincide and are determined mostly by investment opportunities or requirements. In the centrally planned economies, the predominant part of the production capacity is publicly owned and, according to Bor, the socialist State, by establishing through plans the production targets for consumer goods, as well as for the capital goods which are needed for the production of the latter, determines the levels at which human needs are satisfied.<sup>7</sup> In addition, savings by individuals and households are most directly determined by demographic characteristics such as age composition, size and structure of the household and the economic activity status of their members, population growth and so forth. For these reasons the discussion in this section will mainly focus on savings in the household sector.

6. Even though savings and investment may be separate acts arrived at by different decision-makers, they are not necessarily independent. The desired, or *ex ante* savings may differ from the level of investment prevailing at a given time, as reflected in the distribution of production between consumer and investment goods. If the aggregate desired savings exceeds the level of investment, a process of contraction will ensue until the savings is reduced to the level of investment. On the other hand, a deficiency of *ex ante* savings will induce an expansion of output and employment as a result of a higher demand for consumer goods, provided that underutilized capital and labour resources do exist. If the latter condition does not obtain, the movement towards equilibrium will involve inflationary price movements resulting in a reduction of real consumption and, hence, an increase in real savings. This simplified outline of a rather complex argument implies that in discussing savings, the level of investment must also be specified.<sup>8</sup> Unless otherwise stated in the

(Footnote 5 continued)

*Economic Growth* ... (1955), p. 4; Dieterlen, *L'investissement* (1957), pp. 37-40; Meier and Baldwin, *Economic Development* ... (1957), pp. 337-338.

<sup>6</sup> These economies are often referred to as market economies to distinguish them from the centrally planned economies, where supply and demand are conciliated through the decisions of the central authorities, and from the pure subsistence economy, where production and consumption take place mainly within the household unit and exchange between units is negligible.

<sup>7</sup> Bor, *Planovyi balans narodnogo* ... (1959), p. 8.

<sup>8</sup> The argument in its modern form was presented by Keynes, *The General Theory of Employment, Interest and Money* (1951). For a comprehensive discussion of these aspects, see, for instance, Lewis, *The Theory of Economic Growth* (1963), pp. 213 ff.; Dieterlen, *L'investissement* (1957), chap. 4.

following, it will be assumed that investment demand is sufficiently high to make the desired level of savings possible.

7. Savings decisions form part of the fundamental economic choice that permits the allocation of income between current and future use in so far as income can be either consumed or invested. Savings as such may be defined as the excess of income over consumption. No unanimity exists regarding the determinants of savings and different factors are thought to affect public, corporate and private savings. As far as the latter are concerned, their dependence on income and consumption has been generally accepted, but various theories as to the interrelations between income, consumption and savings have been proposed.<sup>9</sup> According to Keynes, consumption will increase with income, though not in the same proportion, and therefore savings as a residual after consumption will depend on income.<sup>10</sup> Another theory, rather than stressing the absolute level of income as a determinant of savings, holds that consumption as well as savings patterns of different individuals and households are interdependent and that an individual's behaviour regarding savings is mainly affected by his relative position in the income distribution.<sup>11</sup> According to a more recent theory, the permanent income hypothesis, consumption and savings decisions are not based so much on present income as on the expected income over the life span.<sup>12</sup> The close relation between age and economic resources in the course of an individual's life and the association of that relation with family status has been noted for a long time,<sup>13</sup> but the development of the permanent income hypothesis together with the research on family formation, growth and dissolution, the so-called theory of the life cycle of the family,<sup>14</sup> has given a prominent place to life-cycle analysis in the income, consumption and savings theory of the family.<sup>15</sup>

## 1. POPULATION SIZE, DENSITY AND SAVINGS

8. Provided that in two populations of differing size aggregate income is the same while savings is the residual after basic consumption requirements have been met, the larger of the two will be characterized by a lower capacity to save than a smaller one. However, this lower saving potential, rather than being due to population size, is a result of lower *per capita* income in the larger population; which has to distribute the same product among more members and has to devote a larger share of total income to satisfying consumption needs. Any inferences regarding the effect of population size on savings should, therefore, take into account the existing level of *per capita* income.<sup>16</sup>

9. Arguments regarding the effect of population size and density on the savings potential have centred mainly on the higher levels of *per capita* public expenditures in small nations. The reasoning is that a country with fewer inhabitants is likely to find itself in a less favourable position than one with a larger population inasmuch as the cost of maintenance of administration and other public services—such as transportation, communications and other public utilities—requires some minimum expenditure, which does not necessarily increase proportionately with the size of the population.<sup>17</sup> If this argument were valid for current public expenditures, the higher *per capita* level of such expenses would, given levels of *per capita* income, lower the saving capacity of smaller nations as compared with larger ones.<sup>18</sup> Little is known, however, about the effects of population size on various categories of government expenditures.<sup>19</sup> A study of current public expenditures—including administration; roads; transportation; government services to labour, agriculture and industry; education; health; mass entertainment and defence—of a few developed countries suggested, according to Robinson, that despite theoretical advantages which would accrue in that respect to larger nations, it was doubtful whether the effect of population size was significant on the whole. As far as specific categories of expenditures were concerned, his tentative conclusion was that only in general administration and defence, economies of scale might favour larger nations in that respect. In some of the categories of expenditures considered, and especially in education, population density rather than population size might, he argued, have some effect on *per capita* spending.<sup>20</sup>

<sup>16</sup> Faaland, "Demographic aspects of savings . . ." (1966).

<sup>17</sup> Vakil and Brahmananda, "The problems of developing countries" (1960); Lewis, *The Theory of Economic Growth* (1963), pp. 72-73. Sauvy, *Théorie générale de la population*, vol. I . . . (1956), pp. 274-276, has pointed out that to the extent that public expenditures are independent of the size of the population, an increase in those expenditures will also raise the size of the optimum population.

<sup>18</sup> This reasoning, it must be remembered, is valid only if it applies to current expenditures. Higher capital outlays under these conditions could, in fact, have the opposite effect on savings if the funds used for financing these projects would otherwise have been used for consumption. On the other hand, higher *per capita* outlays may lead to higher current expenditures for maintenance, servicing and so forth.

<sup>20</sup> Robinson, "The size of the nation . . ." (1960). See also Martin and Lewis, "Patterns of public revenue and expenditure" (1956).

## 2. AGE DISTRIBUTION AND SAVINGS

10. Age and the age distribution of a population are usually considered to be among the most important demographic variables that affect saving capacity and patterns. The importance of the age distribution transcends its own significance also in the sense that the age structure of a population is the result of present and past levels of mortality, migration and especially fertility. The implications of the age distribution for savings manifest themselves both through the nature of the population as consumers and as producers. Since consumption needs are associated with the age of the individual, total consumption requirements and the residual of income for savings are not independent of the age distribution. The mechanism by which the age distribution may affect savings through the production side is somewhat more complex. Age being closely associated with participation in the labour force, the age distribution is one of the main determinants of the proportion of the population economically active and the relation between non-workers and workers, i.e., the dependency ratio. Given the size of the population, this ratio determines the size of the labour force and thus the productive capacity or total output or income. *Per capita* income as the determinant of saving capacity is, however, a function of total income and total population, which includes both workers and non-workers. Thus given the levels of labour productivity, the higher the proportion of dependants the lower will be income per head and the savings potential. In other words, a higher dependency ratio will tend to depress the level of savings, other conditions being the same. Even though conceptually these effects of the age distribution are clear, in practice they may be difficult to assess, both because of other factors involved as well as because of the close association of age with other factors in savings.<sup>21</sup> In addition, the age distribution is essentially a slowly changing characteristic, so that changes in the age distribution are likely to have only a gradual effect on savings.<sup>22</sup>

### (a) Age distribution, consumption and savings

#### (i) Consumption scales, the age distribution and needs

11. People in different age groups have different needs and, with changes in the age distribution, the demand for certain categories of goods and services as well as total needs are likely to change.<sup>23</sup> The age distribution, being a factor in setting total consumption needs will, given the level of income, also determine the part of the latter which could be saved. The study of changing needs with

70.2 .....	19.5	58.6	21.9	876	903

SOURCE: United Nations, *The Aging of Populations* ... (1956), tables 15 and 40.

<sup>a</sup> The needs were calculated on the basis of the following assumptions:

Hypothesis A: the index of the needs of an adult (15-59 years) was assumed to be 1.0; for children (0-14 years) and aged persons (60 years and over) 0.7.

Hypothesis B: the needs of an adult (15-59 years) and of an aged person (60 years and over) were assumed to be 1.0; for children (0-14 years) 0.5.

age is usually based on consumption scales which assign weights to individuals in different age groups according to their needs and which make it possible to express the needs of each individual in terms of adult equivalents.<sup>24</sup> Such weights may be based either on the observation of actual consumption patterns or on studies establishing standard requirements, but in general the results,<sup>25</sup> although they vary considerably, confirm the existence of different consumption needs for persons in different age groups, thus providing indirect evidence of the potential effect of the age distribution on savings.

12. Distinguishing between a few broad age classes—children, adults and aged persons—the needs of children are nearly universally found to be less than those of an adult, but the relation between the requirements of the latter and those of aged persons is less clear.<sup>26</sup> On the basis of one study, which estimated the needs of children and aged to be similar, each representing about 70 per cent of the requirements of an adult,<sup>27</sup> estimated needs per 1,000 population for various stable populations with different levels of expectation of life at birth and gross reproduction rates have been calculated.<sup>28</sup> An alternative calculation, assuming a child's needs to be half those of an adult or aged person was also made<sup>29</sup> (see table XIII.1).

<sup>24</sup> One of the main practical purposes of consumption scales is to express family size in some standard unit which permits a comparison of income levels of families, not biased by family composition. Sydenstricker and King, "The measurement of the relative ..." (1921); International Labour Office, *Methods of Family Living Studies* ... (1949), pp. 28-29.

<sup>25</sup> Various scales as well as their uses and limitations are discussed by Woodbury, "Economic consumption scales ..." (1944). See also Woytinsky and Woytinsky, *World Population and Production* ... (1953); Wold, *Demand Analysis* ... (1953), pp. 221-224; Prais and Houthakker, *The Analysis of Family Budgets* ... (1955); Kleiman, "Age composition, size of households ..." (1966).

<sup>26</sup> See also the discussion in chapter VIII, section D.

<sup>27</sup> Quillon, "Les besoins comparés ..." (1948).

<sup>28</sup> United Nations, *The Aging of Populations* ... (1956), p. 62.

<sup>29</sup> Coale and Hoover, *Population Growth and Economic Development* ... (1958), pp. 238-239, used for India the following weights: 1.0 for each male over 10 years; 0.9 for each female over that age and 0.5 for children below that age.

According to the results, assuming the needs of children and aged persons to be identical, the needs of a "young" population—with a gross reproduction rate of 3.0 and a high proportion of children—are about 4 per cent lower than those of an "old" population—with a gross reproduction rate of 1.0 and comparatively high proportions in adult and advanced ages. Under the second hypothesis, the differences are more substantial: the needs of the "older" population would be about 16 to 18 per cent higher than those of the young population. The change of a "young" population to an "old" one, resulting from a decline in fertility, would thus bring with it a significant increase in the needs per 1,000 population. However, in the process of demographic aging as it has occurred in the past, when both fertility and mortality declined, a compensating effect on total needs occurs owing to the influence of lower mortality on the age distribution.<sup>30</sup> Passing from a stable population with a high fertility and mortality—a gross reproduction rate of 3.0 and an expectation of life at birth of 30 years—to one where both fertility and mortality are low—1.0 and slightly over 70 years, respectively—total consumption needs would increase only somewhat more than 1 per cent under the first assumption, but for the second hypothesis the needs would be raised by as much as 14 per cent (see table XIII.1). Nevertheless, compared to the important shifts in the age distribution and the considerable period which normally would be required to bring about such a transition, the effect on consumption needs and the saving potential is relatively small.

13. A certain controversy persists regarding the effect of compensation on total needs which supposedly would occur as a result of the process of aging. In general, the aging of a population<sup>31</sup> involves an increase in the proportion of persons in adult ages accompanied by an older age distribution of this population and a significantly higher proportion of persons in advanced ages; these increases are compensated by a decline in the relative

<sup>30</sup> United Nations, *The Aging of Populations* ... (1956), p. 62.

<sup>31</sup> The process of aging of a population should be distinguished from individual aging. See chapter VIII, section D.

number of children and young people. The implications of the aging process on consumption needs manifest themselves through the combined effect of these changes,<sup>32</sup> but most of the discussion of the changes in needs associated with the aging process have centred on the question of what effect the shift in the relative importance of children and aged persons would have on total consumption expenditures. A number of authors are of the opinion that an effect of compensation exists in the sense that the increased cost of maintaining the elderly population would be accompanied by lower expenditures for supporting a smaller proportion of children, but most of them are less clear on whether such a compensation would be complete.<sup>33</sup> Those who hold the opinion that with the process of aging the cost of maintaining the dependent population increases base their position on various arguments. In the first place, they contend that the cost of education does not decrease as much as the number of children; the increased years of schooling and the deferment of the age of entry into the labour force would tend to absorb the economies which might have become possible as a result of the decline in the number of children.<sup>34</sup> In the second place, it is argued that the cost of maintaining an aged person is higher than that of maintaining a child.<sup>35</sup> Another circumstance which,

according to some writers, affects the burden of supporting the young as compared with the aged is that while the cost of children is mainly the natural responsibility of the family, the older generation is maintained to a much larger extent by means of taxation or other money transfers. Psychologically, it is argued, the burden may appear to be much heavier in the latter case.<sup>36</sup> A further complicating factor is that, given the different needs of the young and aged, shifts in the age distribution between them will not only change total demand, but also its structure.<sup>37</sup> Even among those who are of the opinion that in principle the aging process makes it possible to reduce in relative terms the expenditures for the young, the view is found that such a reduction will not be automatic nor will an increase in savings necessarily follow.<sup>38</sup>

(ii) *Household size and composition, the age distribution and consumption needs*

14. Findings as to the implications of the age distribution for consumption based on the needs of individuals appear to be on the whole inconclusive. In part this is due to the fact that whereas demographic analysis is concerned mainly with the individual as the basic unit, a meaningful analysis of private savings is possible, as a rule, only in terms of households. Adult equivalent scales, it was found, did not provide for the effects of a varying family composition on the modes of expenditure and the family's consumption appeared to change in more complicated ways than those implicit in the use of those scales.<sup>39</sup> In economics of consumption, it is, therefore, usual to take as the basic entity the household or family.<sup>40</sup>

<sup>32</sup> Eicher, *Consommation et épargne* ... (1961), noted also that much of the literature on the effects of aging limits the discussion to the increase in the number of aged without taking into account the associated changes in the other age groups. See also Spengler, "Aging populations ..." (1963).

<sup>33</sup> Thompson, "Outstanding population trends ..." (1940); Neisser, "The economies of a stationary population" (1944); Letinier, "Vue d'ensemble des conséquences ..." (1948); Fromont, *Démographie économique* ... (1947), p. 144; Kaufmann, *Die Überalterung: Ursachen, Verlauf, wirtschaftliche* ... (1960), pp. 254, 314-315; Stassart, *Les avantages et les inconvénients économiques* ... (1965), p. 56.

<sup>34</sup> Fromont, *Démographie économique* ... (1947), p. 144; Sauvy, *L'Europe et sa population* (1953), p. 79; and his *Théorie générale de la population*, vol. 2 ... (1959), pp. 62-63; and his "La vieillesse économiquement inactive" (1960); Spengler, "Aging populations ..." (1963). For a discussion of these arguments see also Stassart, *Les avantages et les inconvénients économiques* ... (1965), pp. 54-60, who also notes that sometimes it has been argued that the decrease in fertility, which was the main factor underlying the aging process, was partly based on the desire of parents to provide a lesser number of children with a longer and better education. Also, in this connexion, see Spengler, "Population movements, employment and income" (1938). The author observed in more general terms that the changing patterns of living, which contribute to a reduction of fertility and the number of children, may have brought about other changes which prevent an increase or even cause a decline in the propensity to save. Boverat, "Vieillesse de la population ..." (1948), thought that social pressures towards earlier retirement of older persons would, in addition to the later entry of the young into the labour force, increase the dependency load further. However, the increase in the proportions of the population in working ages may ameliorate the tendency towards a higher dependency burden. In the case of Great Britain it was noted that, if as estimated, the working population would grow at a higher rate than the population in inactive ages, this would help to offset the increase in the number of elderly persons. Shenfield, *Social Policies for Old Age* ... (1957), p. 6. The decline of fertility may also make it possible for more women to seek gainful employment. See chapter IX. The effects of the age distribution and aging on dependency is discussed in more detail in the following subsection.

<sup>35</sup> Sauvy, *L'Europe et sa population* (1953), pp. 78, 81-84; his *Théorie générale de la population*, vol. 2 ... (1959), pp. 62-63; and his "La vieillesse économiquement inactive" (1960). Renggli, "Die wirtschaftlichen Auswirkungen der Überalterung" (1938), assumed,

however, that old people tend to consume less than young adults. For a discussion of the higher cost of social services for older persons as compared with children and young people see Paish and Peacock, "Economics of dependence ..." (1954); Shenfield, *Social Policies for Old Age* ... (1957), pp. 12-13.

<sup>36</sup> Fromont, *Démographie économique* ... (1947), pp. 137, 142; Sauvy, *L'Europe et sa population* (1953), pp. 78-79; and his *Théorie générale de la population*, vol. 2 ... (1959), p. 62; and his "La vieillesse économiquement inactive" (1960); Kaufmann, *Die Überalterung: Ursachen, Verlauf, wirtschaftliche* ... (1960), pp. 325-329; Stassart, *Les avantages et les inconvénients économiques* ... (1965), pp. 64-65. Most of these writers point out, however, that under the prevailing family systems in many developing countries, the older generation is directly supported by the household.

(1955), p. 11; Johnson, *Money, Trade and Economic Growth* (1962), pp. 182-187; and David, *Family Composition and Consumption* (1962), pp. 4-6. The latter two authors noted also that in order to take the individual as the basic unit, some theory of the decision-making process within the household should exist. See also Kuznets, "Quantitative aspects of the economic growth of nations, VIII ..." (1963).

In the present context two aspects of family consumption behaviour are of special relevance: first, many goods must be considered as being consumed not by the individual but by the family and, second, there may be substantial economies involved in supporting a larger, rather than a smaller, family and a larger, rather than a smaller, number of dependants. The relations between demographic characteristics and phenomena and those of households are not always well defined and invariable. Household formation, growth and dissolution respond, in addition to demographic factors, to social, cultural and economic conditions. Nevertheless the increase, size and composition of households depend to a great extent, given other factors, on population growth and structure and its determinants—fertility, mortality and migration—and ultimately on the age distribution. While no simple generalization is possible concerning the relation between age distribution and size of households, empirically a younger age distribution is usually accompanied by a larger average size of the household.<sup>41</sup>

15. The significance of the size of households for consumption and savings is twofold: there exists a positive correlation between household size and household income, and variations in household size may account for considerable variations in consumption.<sup>42</sup> Usually, larger families tend to spend more on consumption expenditures of different kinds and much of the evidence suggests that this latter factor dominates the income effect, thus making for a potential negative effect of family size on savings. An early survey in the United States revealed that, while families without children or with only one child were able to save on the average a small but not insignificant part of income, families with two or more children showed only a very small margin between income and expenditure.<sup>43</sup> According to a study undertaken in the United Kingdom, the proportion of families having no national savings certificates was much higher among families with three or more children than in husband-wife families.<sup>44</sup> In order to determine the effect of family size on consumption, a method for determining what level of income would be required to satisfy the family's needs when the number of children varied was applied to the results of two pre-war surveys in the United Kingdom and the findings tended to confirm the effect of family size on levels of living.<sup>45</sup> Indirect evidence as to the possible

effects of household size on savings was obtained in a number of investigations on the relations between levels of living and the number of children in the household in France. The earlier of these investigations, limited to working-class families, provided ample evidence of the negative association between levels of living and number of children, despite the counteracting effect of family allowances;<sup>46</sup> a lowering of the levels of living as the number of children in the family increased was also found in the case of employees.<sup>47</sup> A later study, based on French data, estimated the effects of the size of the family on levels of living in more specific terms.<sup>48</sup> An analysis of the income and expenditures of managerial groups in France also showed that with the increase in the number of members of the family, the proportion of income consumed increased and that of income saved declined.<sup>49</sup>

16. The effect of the addition of a member to a household is not limited to the total level of consumption, but extends to the composition of the goods and services consumed, the shift depending to a great extent on whether the commodity is a necessity or a luxury.<sup>50</sup> The findings of a number of studies suggest that with the increase in the size of the family, income being given, a larger proportion of income has to be spent on necessities, thus reducing the level of living and the capacity to save. Henderson found that an increase in family size, without a corresponding higher income, changed especially the expenditure on standard food and different classes of clothing and luxuries, but had only a small effect on other items of expenditure. The impact of an additional child was to increase expenditure on food and children's clothing, which was paid for by a substantial cut in expenditure for adult clothing and luxuries. Parents, according to Henderson, thus curtailed their expenditure on non-essentials to pay for their children.<sup>51</sup> Woytinsky and Woytinsky, among many others, presented evidence that expenditure for food took up a comparatively larger proportion of income

require an increase of nearly 20 per cent to this income in order to maintain the previous level of living. If no additional income would be forthcoming, the family's level of living would decline to that of a family without children and an income of 15 per cent less.

<sup>46</sup> Quillon, "Comparaisons des revenus ..." (1946); Michot, "Comparaison des revenus et des besoins ..." (1947); Girard, "Les budgets familiaux en 1946" (1948); Malignac, "Minimum vital et niveau d'existence ..." (1949).

<sup>47</sup> Tabah, "Niveau de vie des familles suivant le nombre d'enfants" (1951).

<sup>48</sup> Martin, "Niveau de vie des familles ..." (1956), concluded that taking the level of living of a single person as 100, the index for workers' families in which the wife worked, dropped to 87 for one child, to 70 for two children, and to 69 and 62, respectively, for three and four children. In the case of families of government employees where the wife did not work and the level of living of a couple without children was taken as 100, the index decreased to between 75 and 80 for a family with two children, to between 69 and 77 for a family with three children, and to between 61 and 70 for a family with four children, the ranges corresponding to different ranks and income of the employees.

<sup>49</sup> Byé, *L'épargne dans le Marché commun* ... (1963), pp. 375-376.

<sup>50</sup> Prais, "The estimation of equivalent ..." (1953).

<sup>51</sup> Henderson, "The cost of children, parts 1-3" (1949, 1950). The percentage decrease in expenditure on non-essentials was estimated to be about 20 per cent for a single child, 30 per cent for two children, and 35 per cent for three children.

<sup>41</sup> See chapter X. Brady, "Family saving, 1888 to 1950" (1955), pointed out that the economic resources of individuals in different age groups vary, and that at the same time the available resources determine to a great extent whether a person can live independently or must form part of a household with persons able to support him. Particularly children, and to a lesser extent the elderly, the widowed and the disabled, fall into the dependent category.

<sup>44</sup> Madge, *Wartime Pattern of Saving and Spending* (1943), pp. 58-61.

<sup>45</sup> Henderson, "The cost of a family" (1949); and his "The cost of children, parts 1 and 2" (1949, 1950); Nicholson, "Variations in working class family expenditures" (1949). Henderson estimated that the first child in a family with an income of £5 per week would

as the size of the family increased.<sup>52</sup> Houthakker, analysing the effects of the size of households, as well as of income on the expenditure on food, clothing and miscellaneous expenses on the basis of some forty surveys in over thirty countries, calculated elasticities with respect to the size of household. These elasticities, that is the proportionate increase in expenditure which results from a given proportionate increase in the size of the household, were found to be positive for food, small but positive for clothing and housing and predominantly negative for miscellaneous, including luxury, expenditure.<sup>53</sup> In general, these results suggest that with increasing family size, basic expenditures such as those on food would increase at the cost, particularly, of miscellaneous and luxury expenditures, and, in so far as savings might be classified under this category, savings. Kyrk, analysing data for the United States, concluded that a family whose size increased without a change in income would accommodate itself to the new situation by decreasing savings and various other budget categories.<sup>54</sup> Brady and Friedman noted that, in general, all available studies indicated that an increase in the size of the family within the same income bracket would cause savings to decrease.<sup>55</sup> David has drawn attention to another factor which may exert a further unfavourable influence on savings under these conditions: considering that households are likely to exhibit a certain inertia in their preferences and that even after changes in the size of the family occur, consumption patterns may not adapt themselves automatically and immediately, a reduction in the established level of saving would be an immediate consequence if the size of the family increases and income would remain the same.<sup>56</sup>

17. Although an increase in family size is usually associated with higher consumption expenditure, two factors tend to ameliorate some of the less favourable effects on savings. In the first place, the composition of the family tends to vary, especially as far as the age of its different members is concerned, with the size of the family. The number of persons in a family is not a satisfactory measure of its economic size since, from the point of view of needs, the different individuals cannot be considered equivalent.<sup>57</sup> To the extent that larger families are likely to have a larger number of children, whose needs are less than those of an adult, family size is not an entirely satisfactory basis for estimating con-

sumption needs.<sup>58</sup> In the second place, a larger family may have the benefit of considerable economies of scale. Economies of scale in consumption imply that with given levels of income per person, but not per family, a larger household may be able to maintain a higher level of living than a smaller one. The best-known examples of such economies in consumption are found in the case of foodstuffs; they include buying large quantities; buying commodities which are only sold in certain minimum quantities; economizing in the storage and preparation of food and so forth. The economies of scale for other items of consumption are more difficult to specify—one example is the handing down of clothing from older to younger children—and in some cases even diseconomies of scale may exist. In practice, it may be difficult to determine the extent of economies of scale, even if allowance is made for the effect of differences in family composition: differences in levels of consumption may reflect differences which depend on the size of the household; larger families may be inclined to purchase, on the average, goods of lower quality; or any savings resulting from economies of scale may be used to raise consumption or the quality of the goods consumed.<sup>59</sup>

18. Evidence as to the effect of these factors has been found in a number of studies. The results of a survey in France showed that although total expenditures of the family increased with the number of children, they decreased per unit of consumption as the family became larger, a finding confirmed by later investigations.<sup>60</sup> In the case of working-class families in Great Britain it was found that, at the average standard of living of these families, the amount spent on the second child was more than one third less than that spent on the first child.<sup>61</sup> Another study, also based on data for Great Britain, found considerable differences in expenditures for each child as the number of them in the family increased.<sup>62</sup> Data for rural families in the United States revealed that while an increase in the size of the family also increased

<sup>52</sup> Woytinsky and Woytinsky, *World Population and Production* ... (1953).

<sup>53</sup> Houthakker, "An international comparison of household expenditure patterns ..." (1957). He suggested, with many reservations, the following elasticities with respect to family size: food + 0.3; housing 0.0; clothing 0.0; and "miscellaneous" -0.4.

<sup>58</sup> Different methods can be used for taking into account this effect of the age composition of the family. One of them consists of distinguishing a number of different household types according to their composition. An alternative approach consists in the derivation of equivalent adult scales, based not on individual needs, but on family expenditures and taking into account family composition. Sydenstricker and King, "The measurement of the relative ..." (1921); Allen, "Expenditure patterns ..." (1942); Henderson, "The cost of a family" (1949); Friedman, "A method of comparing incomes ..." (1952); Prais, "The estimation of equivalent ..." (1953); Brown, "Economics, nutrition and family budgets" (1955); Prais and Houthakker, *The Analysis of Family Budgets* ... (1955), pp. 127-139; Forsyth, "The relationship between family size ..." (1960); Ferber, "Research on household behavior" (1962); Kleiman, "Age composition, size of households ..." (1966).

consumption, the elasticity of consumption with respect to family size was estimated to be, on the average, only 0.11.<sup>63</sup> More recent data for Canada suggested an elasticity of less than 0.1.<sup>64</sup> As far as specific categories of consumptions are concerned, evidence as to the existence of possible economies of scale is most abundant in the case of foodstuffs. Whereas most findings agree that such economies with respect to foodstuffs exist,<sup>65</sup> evidence as to economies of scale for other items of consumption is much more limited and controversial. Many investigations have shown expenditure on food per unit of consumption to decrease with the number of members in the family.<sup>66</sup> According to Hollingworth and Baines, a survey of food consumption in Great Britain revealed that when income and demographic structure were both held constant, food expenditure for each additional person in the household after two declined progressively. They attributed the smaller *per capita* expenditure to such factors as lower income per head and to the larger proportion of children with lower needs, but the economies which obtained in providing for large numbers were thought to be an important third factor.<sup>67</sup> Girard concluded that although the expenditure on foodstuffs per unit declined with the number of children in the family, the nutritional value did not: he found that although families with three children spent less on food per consumption unit than families with no children, the diet of the former had a higher calorie content and was richer in protein. He attributed this situation, however, mainly to the rationing system which favoured larger families in buying certain products, such as milk, at lower prices.<sup>68</sup> Prais and Houthakker obtained estimates of the economies of scale with respect to food expenditure from pre-war data for Great Britain. The results indicated that of households with the same level of income per person, those with a larger number of members would, as a result of economies of scale, enjoy a standard of living which was higher by 13 per cent of the ratio of their size. However, their findings also suggested that the economies of scale were negligible in the case of clothing and that diseconomies of scale existed in the case of durable goods, but the latter was in their opinion rather the result of

shifts in tastes which accompany a changing family size than of diseconomies of scale in a strict sense.<sup>69</sup>

19. Very few estimates of the quantitative importance of family size and age composition on levels of consumption and savings do exist. Brady has estimated that at given income levels consumption expenditures increase at the sixth root of the family size.<sup>70</sup> Eizenga, on the basis of data for the United States, found that changes in the family size and structure between 1900 and 1950, other conditions (particularly the age distribution and the income distribution) remaining the same, would have led to an increase of the saving-income ratio of nearly 200 per cent. However, his findings also suggested that changes in the age distribution would have led to only comparatively small increases in this rate.<sup>71</sup> In more general terms, the measurement of the effect on saving of the individual's consumption needs and the size and composition of the household in so far as related to age and age distribution is a difficult task. Consumption patterns respond to a great number of factors, among which are the level and distribution of income and assets, the social and cultural environment and the socio-economic group to which the individual or family belongs.

#### (b) *Age distribution, dependency, income and savings*

20. The implications of the dependency burden, as determined by the age distribution, for *per capita* savings manifest themselves primarily through the levels of *per capita* income. The effect of the dependency factor may be illustrated by assuming two populations with an identical number of workers, the same productivity of labour, but differing in the number of dependants and thus also in total population, the population with the higher dependency burden being also larger in size. The total product of these two populations would be the same, but the *per capita* income would be lower in the population with the larger number of dependants, since the identical product would have to be shared by more people. *Per capita* savings in the population with the higher dependency load would tend to be lower as compared with the other population for two reasons. In the first place, even if the proportion of total income saved, or the saving-income ratio would be the same in the two populations, *per capita* savings would be lower in the higher dependency population since total savings would have to be divided among a larger number. However, in so far as savings is a function of income, in the sense that a lower *per capita* income leads to lower savings, the

<sup>63</sup> Tobin, "Relative income, absolute income and savings" (1951); see also Tacke, "Der Einfluss der Bevölkerungsvermehrung ..." (1963). If, however, the lowest income group was eliminated, the elasticity decreased to 0.05.

assumption of an equal saving-income ratio for the two populations must be discarded and a lower ratio assumed for the population with the lower *per capita* income and the higher dependency burden, resulting in further decrease of *per capita* savings in that population. Under these conditions, the difference in *per capita* savings would thus exceed those in income per head.

21. A theoretical model for populations with high and low fertility and correspondingly different age distributions was developed by Coale in order to show, among other things, the income and savings effects of differences and changes in these demographic variables. He found that, under the assumptions made, a population with a high fertility might, because of its higher dependency burden, be obliged to utilize nearly all of its income for consumption. Given the same labour force and the same total income, a low-fertility population would thus be able to save and invest more, and through these higher investments increase its income faster in subsequent periods.<sup>72</sup>

22. The argument concerning the effect of the age distribution on *per capita* savings through the dependency ratio implies various assumptions; it supposes, apart from the effect age distribution has on consumption, a direct relation (i) between the age distribution and the dependency ratio (defined as the ratio between the economically inactive and the economically active population);<sup>73</sup> (ii) between the relative size of the labour force and *per capita* income; and (iii) between *per capita* income and *per capita* savings.

23. As pointed out in earlier chapters, the age composition is one of the factors which determine the distribution of the population between workers and non-workers, since the extent to which people participate in the labour force varies considerably with age. It has become customary in this connexion to divide the population into three broad age groups: children who have not yet reached working age, adults of working age, and elderly persons past working age.<sup>74</sup> Given other factors, in particular, the size of the active population and its level of productivity, an increase in the inactive population means a decrease in the levels of living of the population.<sup>75</sup> High

dependency ratios, it has been noted, would thus make for high consumption and consequently low savings.<sup>76</sup>

24. The actual size of the labour force, however, is not only determined by the age structure of the population; it depends, also, on patterns of behaviour as reflected in the age-specific activity rates. As discussed in an earlier chapter,<sup>77</sup> in many developing countries the pressures resulting from an unfavourable age distribution and low levels of living may elicit a larger labour force participation through earlier age of entry into, and later withdrawal from, the labour force. As far as the latter is concerned, however, it has been found that, on the whole, the less developed countries are unable to counterbalance the effect of an unfavourable age composition through higher labour force participation. In general, the dependency load of these countries is considerably higher than that of the more industrialized nations.<sup>78</sup> In addition, it has been pointed out that the significance of higher participation rates for income is likely to be small, since the productivity of children and aged persons is often very low.<sup>79</sup> In fact, to the extent that children have to leave school at an early age to look for work, the long-term effect of a higher labour force participation of young people on economic progress may even become negative.<sup>80</sup>

25. It has also been argued, however, that the presence of a large number of children in dependent age groups may itself provide an additional incentive to save.<sup>81</sup> According to another view, under conditions where the average size of the family is large and the outcome of conscious planning, having children might be considered simply as one type of consumption chosen in preference to others<sup>82</sup> without, it being implied, affecting necessarily the saving ratios very much.

26. That differences in the age structure and dependency ratios could, in principle, have an important effect on *per capita* income and savings has been suggested by a number of studies. According to Stigler, an economy in which the percentage of children drops from 40 to 25 could, other things remaining equal, increase its *per capita* income by roughly 25 per cent.<sup>83</sup> Spengler noted that the increase in the population aged between 15 and 64 years from under 60 per cent in 1841 to 70 per cent in

(1969), developed the theory of fertility behaviour as part of the theory of choice of the household.

<sup>83</sup> Stigler, *Trends in Employment* ... (1956), pp. 18-19.

1939 in England would permit, by itself, an increase of about one sixth in *per capita* income.<sup>84</sup> Singer, taking the proportion of the population in productive ages in the United Kingdom as a basis, calculated that in a number of developing countries this proportion was one sixth less, which would imply—given other conditions—that output in the developing countries would only for this reason be already one sixth lower than that of Britain.<sup>85</sup>

27. It has been pointed out, nevertheless, that in attempting to estimate the effects of the dependency ratio on levels of income, it would be necessary to take into account that membership in the labour force does not necessarily imply actual employment for the person concerned. The argument has been advanced that although with a given population the magnitude of the potential labour force input depends on the portion of the population in active ages, the age distribution is not necessarily the effective constraint on labour force input. In fact, in many developing countries, high levels of unemployment and underemployment of persons in adult ages prevail and as long as much an under-utilization of the labour force exists, the age structure of the population does not limit *per capita* income.<sup>86</sup> A similar argument was used by Sauvy, who concluded that if the marginal productivity of labour is very low, the addition to the population of a new inactive member, whose needs would be below those of a worker, could have a less unfavourable effect upon levels of living than the addition of a new worker.<sup>87</sup>

28. The effect of differences in the dependency ratio on savings, as a result of variations in the age distribution, is generally assumed to be indirect, in the sense that the dependency ratios would affect *per capita* income and, through the latter, *per capita* savings. Evidence as to the relation between savings and income does exist, but is far from conclusive. According to a United Nations study,<sup>88</sup> total domestic savings, expressed as a percentage of gross domestic product, were as a rule not as high in the developing as compared with the developed countries, but exceptions existed. On the other hand, the study concluded that the experience of the less developed countries offered only limited support for the hypothesis that variations in domestic savings are the result of differences in the level of *per capita* income; differences in the distribution of income and the degree of dependence on the export sector were thought to be factors which played a more important role. Leff, in a recent study based on data for 74 countries in various stages of development, found a high correlation between dependency and saving ratios and, in addition, the results suggested that the direct relation between the dependency and the saving ratio was at least as important as the indirect one through *per capita* income.<sup>89</sup>

29. Of special interest in the present context are the household or private savings. Kuznets, comparing consumption and *per capita* income in fifty-six countries, concluded that a distinct negative association existed between the share of private consumption expenditures in total product and in *per capita* income.<sup>90</sup> The previously cited United Nations study found, however, that in developed countries household savings varied considerably, but that these variations were associated much more with the rate of growth and the distribution of income than with the level of disposable income of the households. Apart from these factors, the age composition of the different populations was thought to have a certain, but not ascertainable effect on savings. As far as the developing countries were concerned, savings did not appear to have been significantly related to the disposable income of the household sector; the factors more likely to be involved were, according to the report, the level of *per capita* income and the distribution of income.<sup>91</sup>

30. In general terms, it has been assumed that neither a very young nor a very old population is likely to have a very high rate of savings. It has been asserted that, given the level of *per capita* income, it would appear that the greatest savings may be possible in a population with a large proportion of adults, such as those presently found in most of the highly industrialized nations.<sup>92</sup>

#### (c) Age distribution, income distribution and savings

31. Another approach to the problem of savings stresses the interdependence of consumption and savings patterns in an economy and argues that both are determined by the relative position of the individual or the family in the income distribution rather than by the absolute level of income. According to Duesenberry, the propensity of an individual to save can be regarded, *ceteris paribus*, as a rising function of his position in the income distribution.<sup>93</sup> It has also been pointed out that the interdependence of consumption behaviour may also be operative among nations; the existence of such a "demonstration effect" among countries would imply that if two previously isolated economies came into contact, the consumption patterns of the richer country might be imitated by the poorer one. Nurkse, in fact, attributes the high propensity to consume in the less developed countries at least in part to this demonstration effect.<sup>94</sup>

<sup>89</sup> Leff, "Dependency rates and saving rates" (1969).

on the rate of population growth and its components. In a stationary population, savings and dissavings will be equal and net savings zero, since the amount saved by persons in the active ages will equal, *ceteris paribus*, the savings used up by the aged. In a growing population, however, the ratio of people of working age to those past working age will be higher than in the corresponding stationary population; hence savings will become, on balance and in contrast to the case of the stationary population, positive.<sup>106</sup> This effect of the age distribution on savings is, however, relevant only if the retired are assumed to live on their lifetime earnings. If the maintenance of the aged is a family responsibility, as is often the case in the less developed countries, no need exists to save for old age and the burden of the aged population should fall on current production. Likewise, if the older people are supported by a social security system which finances benefits from current receipts, no need exists to save for old age in the course of the active life span.<sup>107</sup>

37. Where the provision for old age is left to the individual, the uncertainty he faces regarding the number of years he can expect to survive after retirement may, in the case where he requires substantial security, lead to over-saving. If all individuals want to make sure of having an income for the longest period they could expect to survive, the corresponding savings would be much higher than those required for the average period of survival. This effect may be particularly important if mortality is high. On the other hand, the uncertainties which the individual has to face in making his saving decisions can be eliminated if savings are pooled. If savings for old age take the form of the purchase of life annuities, the cost of them—that is the savings to be made—depends mainly on the levels of mortality and is only to a limited extent affected by the age distribution: the lower the level of mortality for the insured group, the higher will be the cost for the participant.<sup>108</sup>

38. Besides these demographic factors, the importance of savings for old age will depend on a number of other variables, among them the desired standard of living after and before retirement, the cost of annuities and the rate of interest, the average time between saving and dissaving, the level of income and so forth.

<sup>106</sup> Neisser, "The economics of a stationary population" (1944); Harrod, *Towards a Dynamic Economics* . . . (1948, 1963 ed.), p. 45; Modigliani, "The life cycle hypothesis of saving . . ." (1966). On this point see also Duesenberry, *Income, Saving and the Theory of Consumer Behavior* (1949), p. 42.

<sup>107</sup> United Nations, *The Aging of Populations* . . . (1956), pp. 74-82, discusses the burden of supporting the aged under different systems and demographic conditions.

<sup>108</sup> Vincent, "Vieillesse de la population . . ." (1946), argued that in the case of a system of capitalization, as under a system where current benefits are paid out of current contributions, the burden of the aged falls on the society anyway, since the latter has to keep the value of money constant in order to insure the purchasing power of the annuities, a process which takes place at the cost of society. Duesenberry, *Income, Saving and the Theory of Consumer Behavior* (1949), pp. 42-43, noted that the manner in which savings for old age are invested is very important in determining income after retirement.

#### (e) *The life cycle and savings*

39. At the basis of the theory of the life cycle is the observation that in the course of his lifetime the individual passes through a number of distinct stages, which might be studied, in particular, with reference to his family status. The life cycle of a family begins at marriage and continues throughout the life span of the married, being divided into different stages marked by the birth of children, the period of education, that of the departure of children, and that of the death of each of the spouses.<sup>109</sup> The existence of such stages in the economic conditions of the individual and the family is equally obvious. Emerging from adolescence, the youth goes to work, his earnings increasing as he acquires more skills and experience and reaching at some stage a peak, after which income will decline gradually and, on retirement, rapidly.<sup>110</sup> As in the case of the family life cycle, the pattern of these changes, although not completely uniform, is at given times and places sufficiently stable to consider it as a life cycle typical for the great majority of the population. Lansing and Morgan argued that the use of the life cycle as an explanatory variable in an investigation of economic behaviour may be regarded as an alternative to the use of age: the stage in the life cycle at which an individual finds himself is intimately related to his age, and consequently any factor closely associated with one is certain to be associated with the other.<sup>111</sup>

40. The life cycle, according to a number of authors, is also found in the case of personal savings. Nevertheless, the exact nature of a life cycle in family savings is not altogether clear, as it depends both on the income life cycle, as a main determinant of savings, and the life cycle of the family, the different stages of which affect both the level and structure of their expenditures. The findings of different studies suggest that because of the interdependence of these two factors, no necessarily uniform pattern of savings during the family's life cycle emerges. Woytinsky, comparing variations in family income by the age of the family head with variations in the needs of the family according to its size, found that the cycle of the level of living of the family had three low points: one at the beginning of married life, one when the head of the family was in his forties, and one when he was 65 years or older. The high points were found between ages 25 to 34 and from 55 to 64.<sup>112</sup> Analysing data on household savings for the United States, according to the age of the head of the household, Fisher found that, on the average, dissavings were typical for households with a head aged between 18 and 24 years: small savings took place in those cases where the head was between 25 and 34 years or 65 years and over. Average savings were highest in those house-

<sup>112</sup> Woytinsky, *Earnings and Social Security in the United States* (1943), pp. 232-239.

holds where the head was middle-aged, that is between 45 and 64 years.<sup>113</sup> Brady, however, contended that fundamental differences in the standards of living of the population over 30 years were disappearing and that the main effect of the age distribution on expenditures and savings would be that which resulted from its influence on the proportion of single individuals, couples living alone, and newly established couples below that age.<sup>114</sup>

41. Lydell, basing himself on data for the United Kingdom, noted that fluctuations over the life cycle in the number of dependants were to some extent, but not completely, offset by variations in the level of income; an appreciable fall in the average income per person among families with heads aged between 25 to 44 years, and also among elderly people, was found to exist. Nevertheless, classifying savings according to the age of the head of the household, savings were highest in those households where the head was in the middle ages. In general, savings were small in the younger age groups, increased gradually to reach a maximum in middle ages and then declined again to become negative in the most advanced ages.<sup>115</sup> Modigliani and Ando, analysing the same data, thought that the behaviour of the saving-income ratio as a function of age seemed to conform fairly well to the pattern implied by the life-cycle model.<sup>116</sup>

42. The relation between savings and age in the course of a family's life cycle is, however, influenced by another factor: the needs for durable consumer goods which, according to a number of authors, change significantly during the life cycle, and the inclusion or exclusion of expenditures on durables in savings classified by age will substantially influence the results.<sup>117</sup> Morgan asserted that the stage of the life cycle had a considerable impact on expenditures on such goods, starting when the family is founded and has to accumulate a certain set of household goods.<sup>118</sup> Lydall found an appreciable negative correlation between saving and the acquisition of durable consumer goods and, in so far as the latter is considered as a form of consumption, it had an important effect on savings. Contrary to saving patterns, expenditure on these goods was comparatively large in families with a head under 35 years of age, when families are established and growing; they reached a maximum in the 35-44-year age group, and declined sharply after that.<sup>119</sup> Lansing and Morgan found that if expenditures on consumer durables were considered as savings, young married couples saved more than other families.<sup>120</sup> David, who

made a detailed study of expenditures on selected durable consumer goods, including housing, found that the acquisition of some durables appeared to be related more to the age and marital status of the head of the household than to family size. He suggested, however, that the acquisition of assets at particular stages of the life cycle when families reached a critical size or when members reach a particular age, should be further explored.<sup>121</sup>

### 3. POPULATION GROWTH AND SAVINGS

43. An increase in population tends in the first instance to increase the levels of consumption. The influence of population growth on the demand for consumer goods is generally recognized and is evident in the incorporation in models of the size of population as one of the factors on which consumption depends.<sup>122</sup> The effects of population growth on savings are not easily determined in practice, however. Differences in the rate of population growth imply, as a rule, differences in the age distribution, consumption needs and income and these tend to affect savings. These indirect consequences of differences in the levels of population growth manifesting themselves either through such demographic variables as fertility, mortality, migration and the age distribution, or through the levels of income may not be insignificant.

#### (a) Fertility, mortality, population growth and savings

44. The interrelations between the growth of population, in so far as they are determined by the components of natural growth, fertility and mortality,<sup>123</sup> and savings capacity and performance are the result mainly of the interdependence between population growth, its components and the age distribution. The level of fertility, given mortality, will determine the rate of growth of population, but is also a major determinant of the proportions of the population in active and inactive ages, including the distribution of the latter between young and aged dependants; the size and composition of the family; the workload of the housewife and, thus, her availability for work outside the home.

45. To the extent that a lower level of mortality affects the age distribution, it will generally result in a slight increase in both the proportion of young and aged persons.<sup>124</sup> In terms of dependency ratios then, an improve-

(1955), concluded that the adjustment of economic variables for changes in population tended to improve the accuracy of predictions of the levels of savings.

<sup>123</sup> The effects of international migration on savings are discussed later in this chapter.

<sup>124</sup> See chapters V and VIII.

ment in mortality may tend to reduce the population's capacity to save, although probably not in a significant manner. In an indirect way, however, mortality declines may exert a favourable influence on savings for several reasons. As has already been discussed, saving for old age, provided the responsibility for it falls on the individual, may increase if, as a result of mortality decline, the number of years expected to be spent in retirement increases. Also, lessened morbidity and increased capacity to work, associated with lower mortality, would compensate, at least in part, if not outweigh, the adverse effects of a mortality decrease on savings. Finally, the prolongation of life is in itself a primary goal in economic growth and development; hence, whatever the net effect of such a trend on accumulation or on other economic variables may be, these effects should remain subject to the aim of lowering mortality.

(b) *Population growth, economic growth and savings*

46. Population growth is associated with a higher total demand for consumer goods, but implies at the same time an increased potential production as a result of the increase in the number of workers. The effect of population growth on consumption and savings would thus depend on the consequences the increased population would have for employment and income. If it could be assumed that the increase in population would not by itself create employment and income and also that families without income must make some minimal consumption expenditures, then an increase in aggregate consumption and a fall in savings, given income, would be inevitable. Even if it were assumed that income would rise as a direct consequence of population growth, the question whether savings would rise, fall or remain constant would depend on whether the increase in income exceeded, fell short of or equalled the increase in consumption.<sup>125</sup> This net effect on savings is the more important, since savings determine capital formation and thus will affect future economic growth. If population growth would hamper economic growth, it would, therefore, not only discourage savings in the current period, but through its negative effect on capital formation, also hamper future growth of income.<sup>126</sup>

<sup>125</sup> Choudhry and Kotowitz, "Some simple economic-demographic relationships ..." (1967). Anderson, "Population size and demand" (1961), taking consumer demand as a function of income and the size of population and ignoring the effect of the latter on income, distinguished three categories of demand which would respond in a different manner to population size: (A) necessities, which account for a larger share of the consumer's budget at low, rather than at high levels of income, and for which population increase will raise demand; (B) articles which account for the same share of the budget at all levels of income and for which population size is immaterial; and (C) luxuries, which account for a larger share of the consumer's budget at high rather than at low levels of income, for which the effect on demand of population growth will tend to neutralize that of an increase in income. See also Tacke, "Der Einfluss der Bevölkerungsvermehrung ..." (1963).

<sup>126</sup> Spengler, "Demographic patterns" (1954); Coale, "Population and economic development" (1963).

(i) *Population growth and savings in the less developed countries*

47. Contemporary literature on the interrelations between population and economic growth has given a great deal of attention to the problem of total savings, as opposed to savings in the household sector discussed in the preceding pages, and capital formation in the economically less developed countries with low levels of income and high rates of population growth. Many writers believe that voluntary savings in these countries would be insufficient, given the low levels of income, to create capital at the rate needed for economic development. Very low *per capita* incomes make for low total savings and the dearth of savings maintains incomes at a low level.<sup>127</sup> It is often assumed that over-all savings in the poorest developing countries amount to no more than between 4 and 6 per cent of national income.<sup>128</sup> Findings with respect to savings in developing countries show, however, wide variations. Net domestic savings as a percentage of gross domestic product in thirty-one developing countries varied from -4 to 16 per cent over the period 1950-1959. In seven of these countries savings were less than 4 per cent of gross domestic product; in five they were between 4 and 7 per cent; in ten between 7 and 10 per cent; and in nine countries savings amounted to 11 or more per cent.<sup>129</sup> Data for a more recent period, in most cases 1963-1965, revealed that the median of net domestic savings as a percentage of gross domestic product for thirty-three countries was 8 per cent. In six of these thirty-three countries, savings were negative or lower than 4 per cent of gross domestic product; in nine, savings were between 4 and 6 per cent; in nine, between 7 and 10 per cent and, in nine others, more than 11 per cent.<sup>130</sup> However, such figures may underestimate the real capital formation to the extent that they do not take into account investments in kind.

48. Several other factors in addition to low income are thought to be responsible for low savings in these countries. One of these is the distribution of income. Many authors recognize that the potential for savings in the less developed countries is not as low as might be suggested

by the level of income since as a result of the very unequal distribution of income, a large share is retained by the higher income groups, who are most likely to save. The authors point out, however, that much of these savings escape through ostentatious consumption, or are used for speculative or financial gains instead of productive investment or are lost to the country because of transfer abroad.<sup>131</sup> Also, many other savings among large sections of the population are not primarily determined by investment motives, but are hoarded, spent on such luxury goods as jewellery, precious ornaments and gold, used to acquire foreign assets, or to pay for marriage ceremonies, dowries and so forth.<sup>132</sup> Whereas the view that measures to increase voluntary domestic savings alone are unlikely to provide the financial resources needed for development is not infrequently found, many writers are of the opinion that domestic savings in the less developed countries could be much higher than usually assumed if sufficient economic incentives existed or appropriate measures were taken.<sup>133</sup> It is thought that through taxation, the creation of savings institutions, measures designed to change traditional attitudes and so forth, the funds used for luxury consumption and non-productive investment or held in the form of hoardings could be directed into productive investment.<sup>134</sup> However, in general, it is recognized that the potential of capital formation in the economically less developed countries is limited and that in order to bring about a significant increase in their rate of economic growth a substantial volume of foreign capital would be needed.<sup>135</sup>

(1963), pp. 31-35; Hirschman, *The Strategy of Economic Development* (1958), pp. 2-4; Rosenberg, "Capital formation in underdeveloped countries" (1960). Sometimes it has been suggested that consumption could be reduced through inflation, which would raise prices and reduce the volume of consumption. See, however, Lewis, *The Theory of Economic Growth* (1963), pp. 216-225; Belshaw, *Population Growth and Levels of Consumption* ... (1956), pp. 119-123; United Nations, *Measures for the Economic Development* ... (1951), pp. 42-43; Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 308-317.

<sup>134</sup> Another possibility, that of creating additional capital through the use of surplus labour in the production of certain capital goods, has been widely discussed and is considered in section C.

<sup>135</sup> For estimates of the external needs of capital of developing countries see, especially, United Nations, *Measures for the Economic Development* ... (1951), chap. 40; Millikan and Rostow, *A Proposal, Key to an Effective Foreign Policy* (1959); Hoffman, *One Hundred Countries* ... (1960); Rosenstein-Rodan, "International aid for underdeveloped countries" (1961); United Nations, *The Capital Development Needs* ... (1962).

49. The problems of low savings in developing countries are accentuated by rapid population growth. While the prevailing low levels of saving make it difficult to create the productive assets needed to maintain the increased population at the same levels of living,<sup>136</sup> in addition, population growth may tend to further depress savings through the pressure it exercises as a result of increased consumption needs. Unless population growth induces, directly or indirectly, output to expand at least proportionately to its own increase and causes no rise in the propensity to consume, it will tend to increase the proportion of national income devoted to consumption, and a large part of whatever higher output might occur would be dissipated by population increase.<sup>137</sup> The association of high dependency ratios with high population growth further tends to affect unfavourably the rapid increase in savings.<sup>138</sup> "The source for increasing the volume of investment", it has been noted, "is the 'ploughing back' of portions of future increases in income. This task is handicapped if these increases have instead to be devoted each year to sustaining a larger population."<sup>139</sup> "Rapid population growth and the dependency characteristics that go with it" it has also been observed, "tend to reduce the rate of saving and investment and to create employment problems."<sup>140</sup> In many developing countries, it is asserted, savings have been barely sufficient to keep pace with population growth and little, if any, new capital has actually become available for increasing the levels of living.<sup>141</sup>

#### (ii) *Population growth and savings in the more developed countries*

50. Unlike the situation in countries in the process of development, the implications for capital formation of a possible decline in population growth or numbers in the economically advanced countries, received considerable attention some decades ago. Fears as to the negative effects of a declining population on economic growth, in general, and on investment and savings, in particular, found their expression particularly in the so-called "stagnation thesis". According to this thesis, anticipated in some aspects by Keynes and developed by Hansen, Higgins and others, a declining population tends in two ways to diminish the volume of employment and income, namely through (a) reducing the rate of investment and (b) increasing the propensity to save.<sup>142</sup>

<sup>136</sup> See section B of this chapter.

(Continued on next page)

51. According to the stagnation theory, the main implication of a declining population growth was the disappearance of investment opportunities. Views as to the effects of a slower growth of population on savings are less clear. Hansen thought that, given the well-established consumption and savings patterns developed over the past, the decrease in investment opportunities, following the disappearance of the stimulus provided by population growth and territorial expansion, would not spontaneously increase consumption or lower savings.<sup>143</sup> He referred also to the likelihood that increased savings would be associated with a decline in the size of the family.<sup>144</sup> In both cases, the result would be an excess of savings over investment which, because of a failing demand, would cause employment and income to fall, bringing about a drop in consumption and a further contraction in employment and income. Robinson did not agree that a decrease in population growth might increase savings, but saw, on the other hand, no reason to assume under these conditions a decline in thriftiness, which would offset the decline in investment opportunities.<sup>145</sup>

52. Although the stagnation theory has been challenged, especially in so far as it assumed that investment outlets would disappear, so has the contention that savings might increase or not adapt to the existing levels of investment. Terborgh thought that any negative effect which lower population growth would have on investment opportunities would be balanced at least in part by reduced savings. He argued that as a substantial part of savings is motivated by the desire for certain durable goods, such as household equipment and automobiles, that portion of savings might disappear if the demand for such goods contracted as a result of lower population growth. These lower savings would compensate, at least partially, for the decline in investment caused by the lower population growth.<sup>146</sup> The relative importance of factors tending to increase savings and those tending to decrease them is uncertain. Spengler listed the following as factors which might lead to an increasing propensity to consume under these conditions: an increase in the marginal productivity of labour and, therefore, the wage level; the possible introduction of a system of family subsidies in order to promote larger families; and an age distribution more favourable to consumption. In particular, the two first factors would favour mostly the lower income groups, whose savings, as a rule, are

small. These factors, according to Spengler, should be balanced against the possible positive effects on savings which might result from a more favourable ratio between population and resources and other implications of the lower population growth.<sup>147</sup>

53. More recently, the argument, at least in developed countries, that population growth could call forth forces which would tend to augment savings has been advanced, in particular by Kuznets. As reasons for his argument, he mentioned that where population grows through natural increase, not all the added outlays would necessarily be at the expense of otherwise proportionately larger savings. A higher number of children may in fact provide an incentive to save more. Likewise, some components of saving tend to increase when the population is growing, this being particularly true of savings for old age and future expenses. Finally, to the extent that consumption patterns are interdependent, the lower levels of consumption in low-income families which would result from population growth could depress the levels of consumption in higher income classes and in this manner raise their savings.<sup>148</sup> Stassart thought, however, that it was doubtful whether population growth by itself would lead to higher private or public savings, but argued that it might have a positive effect on corporate savings.<sup>149</sup>

#### 4. INTERNATIONAL MIGRATION AND SAVINGS

54. International migration may have various effects on savings. By influencing the age distribution and the ratio of workers to dependants, it may affect the levels of income and consumption, and thus savings. In addition, there are the direct effects international migration can have on income and income distribution and the saving capacity. Finally, there are the movements of capital and transfer of funds which occur as a direct result of international migration, and which may affect capital formation both in countries of emigration and immigration.

55. The influence which international migration can have on savings capacity through its effects on the age distribution and the ratio of workers to non-workers is twofold. International migrants may have labour force participation rates which differ from those of non-migrants, but, more importantly, the migrants are likely to include higher proportions of persons in the sex-age groups where activity rates are high.<sup>150</sup> Changes in the age composition resulting from migration will have implications for savings not unlike those discussed in the preceding subsections.

56. Emigration or immigration, by reducing or increasing the population, may indirectly affect savings in the long run through induced changes in the levels and distri-

<sup>150</sup> See chapter VII, section D.

bution of income.<sup>151</sup> Voluntary migrations, it is often pointed out, respond to a great extent to the expectation or desire on the part of the migrant to improve his standard of living.<sup>152</sup> In general, the aggregate income in the countries of immigration would almost certainly increase as a result of immigration. As for *per capita* income, immigration is held to be advantageous in sparsely settled countries where an inflow of immigrants would make it possible to use natural resources more effectively<sup>153</sup> or, in general terms, where the population is below optimum size.<sup>154</sup> The effect which international migration can have on consumption, as one of the main determinants of saving, is not entirely clear. It has been argued, on the one hand, that to the extent that immigrants are often used to living at lower levels prior to migration, they may not immediately adopt the patterns of consumption of the countries of immigration, and thus, out of a given income, are able to save more.<sup>155</sup> Isaac has also noted that since immigration requires additional capital outlays for installing and equipping the immigrants, these investments may have to be obtained through a contraction of consumption.<sup>156</sup> Finally, there are the effects which immigration may have on the distribution of income through its effect on wages.<sup>157</sup> By potentially lowering the wages of the unskilled labour market, in which immigrants compete most directly with native workers, income in other occupations might tend to increase in relative terms, thus increasing the saving capacity of these workers.<sup>158</sup>

57. A last factor to be considered in the present context is the effect on savings of capital movements directly associated with immigration or emigration. These capital transfers can take the form of: (a) funds brought in by immigrants; (b) remittances by immigrants; and (c) funds taken out by returning migrants. The available evidence suggests that while the first type of transfers may be of relatively little importance, remittances by immigrants and capital taken out by returning migrants may sometimes be substantial. Migrants have been said to save considerable amounts, even from meagre incomes, especially if they had families to support in their coun-

tries of origin.<sup>159</sup> These remittances, which in recent times have become important, especially in shorter intra-continental movements,<sup>160</sup> tend to affect savings both in countries of emigration and immigration. According to Sauvy, saving for this purpose will make more of a difference in the country of immigration, because the immigrant who saves would curtail in particular those expenses which would have been most beneficial for the country.<sup>161</sup> Immigrant remittances received in the countries of emigration, according to a number of writers, have contributed considerably to relieve the existence of population pressure.<sup>162</sup> Lewis thought that, though these remittances, as a rule, were a minor part in the balance of payments, they lightened the burden which countries of emigration had to suffer because the young people were leaving.<sup>163</sup> In addition to remittances by immigrants, considerable funds have been taken back by returning migrants to their countries of origin.<sup>164</sup>

## 5. INTERNAL MIGRATION AND SAVINGS

58. The possible effects of internal migration on savings are in some aspects similar to those of international migration, but in others, different. Like international movements, internal migration may affect levels of saving through changes in the level of income, but it does not cause direct changes in the age distribution of the nation's population, nor as a rule does it influence international movements of capital in a direct manner. Nevertheless, age selectivity also operates in internal migration and changes in the age distribution resulting from these internal movements, together with differences in labour force participation rates and levels of productivity, may in turn affect income and savings. Likewise, the transfer of money by migrants to their families or relatives who remained behind may not be without its effect on levels of saving. In general, with the possible exception of the effects of rural-urban migrations, little is known about the consequences of the redistribution of the population within a country for levels and patterns of savings.

### (a) Rural-urban migration, urbanization and savings

59. Since rural-urban migration responds to a great extent to economic factors, particularly the real or assumed better opportunities for employment, these movements are heavily weighted in favour of young adults and thus frequently cause significant changes in the age distribution of both urban and rural populations. While this characteristic might make for a lower dependency ratio in urban areas, this does not necessarily follow since as a rule

<sup>151</sup> Thompson, "The demographic and economic implications . . ." (1947), thought that, in the case of the United States, migrants might have contributed to a relatively high rate of population growth which was possibly one factor in that nation's rapid economic expansion.

<sup>164</sup> Isaac, *Economics of Migration* (1947), p. 247; Taft and Robbins; *International Migrations . . .* (1955), p. 80.

labour force participation rates, at least for males, are higher in rural areas, mainly as a result of earlier age of entry and later age of withdrawal, and the effect of a more favourable age distribution in urban areas on economic activity rates may be compensated for by the higher participation rates in rural areas. Findings in this respect seem to be far from conclusive.<sup>165</sup>

60. Evidence as to the effect of income differentials between urban and rural areas on savings is likewise inconclusive. Although it has been argued that in the developing countries, rapid urbanization might appear to create the conditions for increasing savings, by developing the monetary economy, stimulating the circulation of goods and services and through expanding public institutions concerned with savings, it is also recognized that this result does not necessarily follow. A closer examination of changes in patterns of living and consumption following urbanization suggests, in fact, that very rapid urban growth tends to reduce the rate of savings. Whereas the saving capacity of low-income urban groups is very small, savings in the urban higher income groups is reduced by the high propensity to spend.<sup>166</sup> A number of comparative studies have established the fact that, at the same level of income, the rural population saves more than the city population and the evidence suggests, moreover, that these differentials persist if the population is further subdivided, e.g. into small town and city population, or according to the size of towns and cities.<sup>167</sup>

61. A number of explanations have been proposed for such differentials. One of them is that rural savings appear higher because in rural areas part of the household production and consumption escapes measurement, as a result of which income and consumption are underestimated.<sup>168</sup> Other interpretations accept the existence of a higher propensity to consume in urban areas, attributing it both to the higher cost of living (the fact that the urban consumer must pay more for certain goods and services) and to the standard of living (the fact that the urban consumer leads a more expensive type of life in the urban community).<sup>169</sup> Some authors have pointed out that the rural population spends less on such consumption items as housing rents, transportation and also on durable consumer goods, although apparently not on food.

<sup>165</sup> See chapter IX. It has been argued that a higher dependency ratio in rural areas might also be compensated for by remittances of migrants to their families. United Nations, "Implications of population trends ..." (1963).

Also Faaland, "Demographic aspects of savings ..." (1966).

<sup>168</sup> Kuznets, "Quantitative aspects of the economic growth of nations, VII ..." (1962); Byé, *L'épargne dans le Marché commun* ... (1963), p. 389.

<sup>169</sup> Morgan, "Factors related to consumer saving ..." (1954); Kuznets, "Quantitative aspects of the economic growth of nations, VII ..." (1962).

However, findings in this respect often differ.<sup>170</sup> Byé thinks that, in addition, farmers have usually stronger incentives to save because of such factors as the need to build up reserves against bad harvests, the cycle in agricultural activity during the year, as well as the fact that many of them are individual *entrepreneurs*.<sup>171</sup>

62. Several authors have concluded from the fact that, with given income, saving is higher in rural than in urban areas, the increasing urbanization in the developed countries in the course of the last century has been a factor in the stability of the average propensity to consume.<sup>172</sup> Duesenberry has shown, however, that this factor could have increased the propensity to consume by one per cent at most in the course of the last fifty years.<sup>173</sup> Nevertheless, in general the redistribution of population operates, according to Spengler, to reduce the supply of savings in the long run, if, as it appears to be the case, such a process transfers people from situations in which the propensity to consume is relatively low to situations in which it is relatively high and if the effects of this transfer are not offset by accompanying increases in *per capita* income.<sup>174</sup>

## 6. DEMOGRAPHIC AND NON-DEMOGRAPHIC DETERMINANTS OF SAVINGS

63. The foregoing discussion has been concerned primarily with the possible influences of demographic factors on savings and, particularly, savings in the household sector, to the virtual exclusion of non-demographic determinants of this process. The arguments reviewed suggest that demographic factors may affect savings in a number of ways, and that population may play a significant, though not a crucial role, in savings decisions and performance.

64. Many of the arguments surveyed relate to demographic factors as determinants of savings capacity, or motives for saving, especially in the household sector, and it is difficult to determine to what extent these factors are important for actual savings levels and patterns. It would appear that only in the extreme cases where consumption is depressed to its subsistence level are actual savings likely to be greatly influenced by savings capacity, as determined by demographic factors among others. In other cases, the savings capacity is mainly useful as a theoretical concept, reflecting the lower levels of consumption. The actual levels and patterns of savings of households under these circumstances will depend to a great extent on other factors, such as levels and distribution of income. The direct effect of demographic factors may thus not be so evident, though they may of course have indirect repercussions on the main determinants of savings.

<sup>170</sup> Byé, *L'épargne dans le Marché commun* ... (1963), p. 389; Dewhurst et al., *Europe's Needs and Resources* ... (1961), p. 156.

<sup>172</sup> Kuznets, "Proportion of capital formation ..." (1952); Smithies and Mosak, "Forecasting postwar demand" (1945); see also Eicher, *Consommation et épargne* ... (1961), p. 32.

<sup>173</sup> Duesenberry, *Income, Saving and the Theory of Consumer Behavior* (1949).

<sup>174</sup> Spengler, "Economics and demography" (1959).

65. On the whole, a number of the findings discussed suggest that demographic factors may exert an influence on savings in the household sector, be it directly or indirectly. The problem lies mainly in assessing the impact of population in quantitative terms and its relative importance as compared to other determinants. In addition, it must be taken into account that the studies reviewed in this section dealt, with only few exceptions, with savings in the household sector. To the extent that the importance of this kind of savings is or was minimal, as in the centrally planned economies; insufficient, as in the developing countries; or declining in relative terms, as in the case of many developed, private enterprise economies, the role of demographic factors is further circumscribed.

66. It is within this context that the influence of demographic factors as compared with non-demographic determinants of savings must be considered. Although the available evidence is incomplete and this discussion has singled out mainly the demographic aspects, the findings nevertheless suggest that population and demographic factors may play a significant, though not a crucial role, in private savings.

## B. Demographic aspects of investment

67. Whereas the foregoing section dealt mainly with demographic factors in so far as they affect the supply of part of the funds available for capital formation, the present section is primarily concerned with the problem as to how these factors influence the demand for and the availability of capital goods and investment. The problems of defining investment are multiple, in part because the word has been used in different meanings, including that of the actual spending of money for the purchase of capital goods or even the acquisition of securities or other financial claims. Investment in cash or kind in the sense of capital formation has been interpreted in two ways, the first giving emphasis to the capacity of the goods concerned to satisfy future needs, the second stressing the nature of investment as contributing to the future production process. Those who stress the former approach are inclined to consider expenditures on at least some durable consumer goods as investment; while those who emphasize the contribution of capital goods to future production as the basic element in investment tend to exclude all durable consumer goods, except in most cases dwellings, from capital formation, but would include certain other expenditures which would facilitate future production. To the extent that the latter can be increased not only through the additions to the stock of capital goods, but also by higher levels of education, technical training and knowledge on the part of the population, by improvements in health and living conditions and so forth, expenditures in these fields are to an increasing degree being considered as "investment in man" and as increasing the "human capital". Thus, depending on the purpose, the range of items included in capital formation may vary from a narrow interpretation, which includes only physical plant and equipment, to one which also includes current expenditures for research, health and, particularly, educa-

tion, in so far as they contribute to improved technology and increased productivity of labour.<sup>175</sup>

68. The determination of the stock of capital goods and of investment involves a number of problems. In national income accounting, the definition of investment used is, for practical reasons, mostly a narrow one and would include as a rule two types of capital formation: investment in fixed capital, consisting of dwellings, non-residential buildings, other construction and works, transport equipment, machinery and other equipment; and, inventories which include raw materials, unfinished products, and finished products meant to be sold.<sup>176</sup> An important distinction in capital formation is that between gross and net investment. In each period capital goods are used, they are subject to wear and tear, obsolescence and accidental damage, and this process, sometimes referred to as capital consumption, means that some portion of the current production of capital goods must be set aside to allow for capital consumption and to maintain intact the stock of physical assets. Gross investment, then, refers to the total output of capital goods and net investment is differentiated from it in that it is measured after allowances are made for depreciation, obsolescence and accidental damage of the capital goods in a given period.<sup>177</sup>

69. It has become customary in demographic literature to distinguish a number of different types of investment and, although the classifications used differ, they bring

<sup>175</sup> For a discussion of general problems concerning the definition of capital and investment see United Nations, *Concepts and Definitions of Capital Formation* (1953); Kuznets, "International differences in capital formation and financing" (1955); Spengler, "Capital requirements and population growth ..." (1956). For an early review of definitions of capital, see: Fisher, *The Nature of Capital and Income* (1912), chap. 4. Definitions of capital and investment in a narrow sense may be found in: Dieterlen, *L'investissement* (1957), pp. 21-31; Kindleberger, *Economic Development* (1965), pp. 84-85; Clark, *The Conditions of Economic Progress* (1957), p. 566; Peterson, *Income, Employment and Economic Growth* (1962), pp. 43-45, 198. A broader definition of capital and investment is found in: Hicks, *The Social Framework* ... (1952), p. 73; Sauvy, "Investissements démographiques ..." (1959). On the subject of "investment in man" and "human capital", see: Adler, "The fiscal and monetary implications ..." (1952); Belshaw, *Population Growth and Levels of Consumption* ... (1956), pp. 108-109; Schultz, "Investment in human capital" (1961); Bonner and Lees, "Consumption and investment" (1963); Robertson, "Stability and progress ..." (1958); Kuznets, "Population, income and capital" (1954); Viner, "Stability and progress ..." (1958). Keynes, *The General Theory of Employment, Interest and Money* (1951), pp. 61-62, noted that a uniform definition of capital and investment was not essential as long as the one adopted is reasonable for the purpose it is to serve.

<sup>176</sup> United Nations, *Concepts and Definitions of Capital Formation* (1953), pp. 14-15.

<sup>177</sup> *Ibid.*, pp. 9, 11-14; Peterson, *Income, Employment and Economic Growth* (1962), pp. 45-46. One of the main problems in the measurement of capital formation, which is the estimation of the actual volume of capital goods expressed in terms of money value, is even felt more severely in the case of capital consumption and net capital formation. Whereas, in principle, gross investment can be measured without too many problems, capital consumption can as a rule not be observed and must, therefore, be imputed. Kuznets, *Capital in the American Economy* ... (1961), pp. 58-60. The concept of "new investment" used in socialist countries is defined as gross investment from which are subtracted discarded fixed assets valued at replacement cost and by accidental damages of capital. See: United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1955* (1956), p. 198; Shonfield, *Modern Capitalism* ... (1965), p. 6.

out the fact that capital formation can take different forms, each of which has its own significance. One such classification divides capital into directly productive and not directly productive capital, or social overhead capital. While the former stands for investment in enterprises in the usual sense, not directly productive capital is defined as those basic services, which although themselves not directly productive are essential for the functioning of productive activities in a narrow sense. In its more restricted meaning, social overhead capital consists mainly of transportation, communications and power, including thus roads, railways, telegraph, telephone, power installations, waterworks and so forth. The investments in these types of activities are sometimes referred to as investments in infrastructure. In its broader sense, social overhead capital includes all public services, among them the maintenance of law and order, other aspects of administration and also education and public health.<sup>178</sup> Another classification distinguishes between enterprise capital, social overhead capital in the sense of investment in infrastructure and human capital.<sup>179</sup> To the extent that investments in infrastructure are really not "social", it has been suggested that the expression economic overhead capital should be used for them and to limit social overhead capital to social investments in their narrow sense.<sup>180</sup> In relation with a similar classification—private investment, investment in infrastructure and social investment—it was noted that social investment played a double role in the sense that it not only increased man's capacity as a producer, but contributed at the same time to his well-being, which is the ultimate goal of economic growth.<sup>181</sup>

70. The role of capital formation in the process of economic growth has been widely discussed in economic literature. As a reaction to a one-sided emphasis on investment in the physical stock of plant and equipment, particularly in the developing countries, it has been stressed that capital is not the only factor in economic growth, but it is also recognized that it remains important. This is especially true where investment is used in its broader sense to include investments in infrastructure and human capital. Although not denying the importance of directly productive capital, a number of writers have stressed the importance of investment in infrastructure,<sup>182</sup> and in view of the impossibility of explaining long-run trends in economic growth in terms of physical capital, or employment,<sup>183</sup> recent literature has directed its attention to

other factors in economic growth, among which human capital was considered to be one of the most important.<sup>184</sup> Although the importance of human capital for economic growth has been widely recognized,<sup>185</sup> the problems of defining the concept<sup>186</sup> and of the valuation of the relevant investment<sup>187</sup> remain important obstacles to an adequate analysis of the role of this factor in economic growth.

71. The importance assigned to demographic factors in the process of capital formation has increased considerably in recent decades as a result of the increasing preoccupation with economic growth and the implications of demographic trends for the latter in many developing countries. However, in view of the limited saving capacity of these countries, this discussion has been mainly focused on the requirements for capital formation which result from the high levels of population growth and associated demographic characteristics found in many of these countries. Much less is known about the actual influence of demographic factors on the level and structure of investment. As far as the economically more developed countries are concerned, the effect of demographic factors on investment has been primarily discussed, especially a few decades ago, in the context of a decline in population or its rate of growth, which was thought to affect unfavourably the investment opportunities and the outlook for economic growth. However, since such a demographic trend is no longer clear and the other premises on which this "stagnation thesis" was based appear not to have been confirmed, attention in these countries has shifted more to the ways in which demographic factors may affect investment in specific sectors, such as education, housing, transport, urban facilities and so forth. In the socialist countries, according to Bor, the needs of the economy and population are established in the preparation of plans and, depending on the level of development and the country's possibilities, the resources necessary for the allocations of these needs are determined.<sup>188</sup>

<sup>181</sup> Piatier, *Equilibre entre développement économique* ... (1962), pp. 46-57, discusses also the classifications of capital and investment suggested by other authors.

<sup>182</sup> For instance, Rostow, in "The take-off into self-sustained growth" (1956), places special emphasis on the role of railways as initiators of rapid economic growth. See also Bruton, "Growth models and underdeveloped countries" (1955); Adler, "The fiscal and monetary implications ..." (1952).

<sup>183</sup> Among the studies on economic growth, which revealed the inadequacy of capital and labour as explanatory factors, see Denison, *The Sources of Economic Growth in the United States* ...

## 1. POPULATION SIZE, DENSITY AND INVESTMENT

72. To the extent that the satisfaction of the needs of each individual presupposes the existence of certain capital goods, the total capital requirements of a population are not independent of its size. A larger population having a larger working force will need more capital to provide the workers with the needed equipment, plants etc., and it will also require a higher investment in infrastructure and human capital. Of more importance in the present context is the question whether the size of the population, and also its density, will have any effect on *per capita* capital needs. It may be argued that whatever the size of the country some minimum expenditures, both current and on capital, have to be made and that, other conditions remaining the same, a smaller country may find itself in this respect in a less favourable situation than a larger one. As has been discussed earlier in relation to current expenditures,<sup>189</sup> the functioning and maintenance of administration and other public services require certain investments, which may be to some extent independent of the size of the nations. Similar considerations relate to the effect of population density on investments, and it is possible, in fact, that density might even have a more important effect than the size of population, since the types of services, such as transportation, communications and so forth, are likely to depend more on the patterns of settlement of the population and its density than on its size. Meaningful comparisons of *per capita* investment in this respect are, however, difficult since besides "technical" factors, social and political considerations determine these categories of capital outlays.

73. Many writers have noted that a larger population may have the benefit of considerable economic advantages stemming from the possibilities of an increased division of labour and other economies resulting from large-scale production. Such economies of scale would raise the levels of productivity of the factors of production, including capital,<sup>190</sup> and thus given the level of *per capita* income, the investment needs might be correspondingly lower in a larger population. While diseconomies of scale arising with respect to certain products and activities may give rise to an international division of labour, some investments in such sectors as transport, communications, education, health and housing, among others, do not lend themselves easily to the international division of labour or the productivity criterion to which other products or services may be subjected. These limitations of the productivity criterion and the international division of labour<sup>191</sup> are found in both smaller and larger nations, and the question whether their adverse effect upon capital requirements will be greater in the one or in the other is difficult to answer, since besides the factors here mentioned, the actual levels of investment in these activities will, to a considerable extent, be determined, as noted, by other considerations.<sup>192</sup>

<sup>189</sup> See section A of this chapter.

<sup>190</sup> See section D of this chapter for a discussion of the effects of population size on economies of scale and productivity.

## 2. AGE DISTRIBUTION AND INVESTMENT

74. The implications of the age distribution for capital formation are basically the result of the fact that an individual's needs and his economic status are closely associated with his age. Differences in the age distribution, which imply variations in the relative numbers of workers and non-workers and the structure within each of these groups, may affect capital requirements in different ways. In the first place, a higher proportion of workers in the total population will create a need for a larger share of productive capital in order to provide the workers with the necessary machinery, tools, equipment and so forth. On the other hand, in so far as a higher dependency ratio is associated with a lower ratio of the working to the total population, the maintenance of the same *per capita* income in a population with a high dependency ratio as in that with a low dependency ratio will require a higher productivity per worker in the former. This in turn is likely to be accompanied by a higher per worker requirement for capital and possibly a higher *per capita* outlay. In the second place, to the extent that the different needs of members of given age groups include to a varying degree expenditures to be classified as investment, differences in the age distribution may thus be associated with different requirements for investment in certain types of social overhead and human capital. Although the effect of the age distribution on investment in productive capital is not independent of its effect on social overhead and human capital, in general it may be thought that the age distribution may affect both the level and composition of investment.

75. Little is known about the over-all effect of the age distribution on investment levels and structure, but some of the literature discusses the effects the dependency ratio has on the structure of investment and the levels of not-directly productive investment. The argument is that in so far as the care and maintenance of the dependent population presupposes the existence of a given stock of capital, which includes schools, health facilities, such as hospitals, residential housing and others, the larger the proportion of dependants, the higher will be the share of these not-directly productive investments in the total. Particularly in the case of developing countries, it was noted, a high dependency ratio resulting in a diversion of capital into various activities, which are not directly productive, tends to impede the growth of productive capital and, therefore, the rate of economic development.<sup>193</sup>

76. The age composition is an important factor, especially as far as investments in education are concerned. The larger the proportion of children of school-age in the population, the greater will be the proportion of national income which must be spent to provide education at a given standard.<sup>194</sup> Likewise, the age structure of the

<sup>193</sup> Singer, "Population and economic development" (1955); Hicks, "A note on the burden ..." (1965).

(1950), vol. 3, pp. 48-49; Eicher, "La rentabilité de l'investissement humain" (1960); Piatier, *Equilibre entre développement économique* ... (1962), pp. 34-35; Phillips, "Education and development" (1964); Harbison and Myers, *Education, Manpower and Economic Growth* ... (1964), p. 36.

population may be related to the demand for housing. Other factors being equal, the needs for investment in housing may be greater in countries with an older population, given the smaller size of the household associated with lower fertility, the lower proportion of child dependants who live as members of a household, and the higher proportion of aged dependants, some of whom will live by themselves. However, the size of the dwelling required in a young population may on the average be larger than in an old population.<sup>195</sup> Differences in the age structure may also influence investment in health and health facilities, and in other activities of social welfare.<sup>196</sup>

### 3. POPULATION GROWTH AND INVESTMENT

77. The literature on the effect of demographic factors on investment has given special attention to the consequences of population growth for capital formation. The significance of the former for investment rests on the fact that an increase in population assumes, under normal conditions, a rise, though not necessarily proportional, in the stock of capital goods in order to provide the larger population, or labour force, with the necessary material equipment and capital goods. Much of the literature on the interrelation between population growth and investment is concerned with the consequences of a lack of correspondence between the rate of expansion of the two, either because the actual rate of capital formation tends to fall short of the required rate, as in the case of many developing countries, or because the rate of population growth shows a tendency to remain below the prevailing rate of capital formation, as was feared in the case of the economically more developed countries some decades ago.

#### (a) *Population growth and the required rate of investment*

78. The effects of population growth on investment may be illustrated by means of a simplified model of an economy, based on the analysis of the process of economic growth originated by Harrod and Domar. The point of departure of this so-called Harrod-Domar model is that economic growth is associated with an increase in capital.<sup>197</sup> In its most simple form, the Harrod-Domar type model, first, takes an increase in output as a function of current investment and the capital-output ratio and secondly, relates the increase in income to the increase in

investment and the inverse of the marginal propensity to save.<sup>198</sup>

79. The studies on the effects of population growth on investment requirements based on the Harrod-Domar model depart from the premise that an increase of output or income depends on an addition to the stock of capital. The ratio between a net increase in the stock of capital, that is net investment, and the increase of output associated with it determines the amount of investment needed to obtain a given increase in output. This ratio which is variously called the marginal or incremental capital-output ratio or capital coefficient, may be simply defined as the investment needed to produce an additional unit of output.<sup>199</sup> For instance, assuming a marginal capital-output ratio of 4 to 1, this means that in order to raise national income by 1 per cent, an annual net investment of 4 per cent of national income is required. For an increase of output of 2 per cent, the investment should be raised to 8 per cent and so on.

80. The impact of changes in population size on investment requirements can now be evaluated. Given the above assumption, an increase of population of 1 per cent calls for a total output also 1 per cent higher if *per capita* income is to be maintained at its previous level. This increase in total output will require an investment which, in the case of a marginal capital-output ratio of 4 to 1, represents 4 per cent of national income. The effects of the level of population growth on investment needs can be seen by comparing two hypothetical economies characterized by the same capital-output ratio, but with differing rates of growth of population. Assuming the capital output ratio to be 4 to 1 and the rates of population growth 1 and 3 per cent annually, the first population will, as seen before, have to invest 4 per cent of national income in order to maintain *per capita* income. However, the population growing at the rate of 3 per cent will need to raise its income by 3 per cent, if *per capita* income is to remain the same, which will require an investment rate also three times as high as in the first population, or 12 per cent of national income. From this illustration it is clear that a high rate of population growth will require a very high rate of capital accumulation merely to maintain the existing levels of income or, alternatively stated, given a certain level of capital accumulation, economic

<sup>195</sup> Henry, "Structure de la population et besoins de logements" (1949); United Nations, *The Aging of Populations* ... (1956), pp. 70-72.

<sup>196</sup> Perrott and Holland, "Population trends and problems of public health" (1940), pp. 359 ff.; Kuznets, "Quantitative aspects of the economic growth of nations, VII ..." (1962).

<sup>197</sup> Harrod, "An essay in dynamic theory" (1939); and his *Towards a Dynamic Economics* ... (1948, 1963 ed.). Domar, *Essays in the Theory of Economic Growth* (1957), contains a collection of his writings on this subject. Both Harrod and Domar were not so much concerned in their analysis with the requirements of capital formation, but rather the opposite problem. Harrod, noting that a change in output would affect current investment, inquired whether a given rate of income growth would be high enough to adduce additional investment expenditures sufficient to absorb current savings. Domar took as his point of departure the fact that net investment raises the productive capacity and, given this effect of investment, he set out to determine how income had to grow in order to maintain full employment.

<sup>198</sup> For a discussion of Harrod-Domar models, see Baumol, *Economic Dynamics* ... (1951), pp. 36-54; Hamberg, *Economic Growth and Instability* ... (1956); Meier and Baldwin, *Economic Development* ... (1957), pp. 100-112; Higgins, *Economic Development* ... (1959), pp. 144-166; Peterson, *Income, Employment and Economic Growth* (1962), pp. 475-503.

<sup>199</sup> Much literature exists on the subject of the capital-output ratio including the works of Harrod and Domar. See, for instance, Lewis, *The Theory of Economic Growth* (1963), pp. 201-213; Leibenstein, *Economic Backwardness* ... (1957), pp. 176-184, 195-198; Belshaw, *Population Growth and Levels of Consumption* ... (1956), pp. 90-99; Tinbergen, *The Design of Development* (1958), pp. 70-76. A distinction must be made between the marginal and the average capital-output ratio, the latter being the quantity of capital needed for the production of a unit on the average, whereas the former relates net additions of capital or investment to the corresponding increase in output. While both ratios may be the same, they are not necessarily so. Sauvy, "Investissements démographiques ..." (1959), criticized the use of the expression capital-output ratio and suggested the use of its inverse, which is the capital "productivity", calling it the "national rate of interest or return".

growth, i.e., increasing *per capita* income, will be much slower in a population characterized by a high rate of population growth than in one where growth is slow. Returning to the previous illustration and assuming net investment to be 12 per cent of national income in both economies, the one with a population growth of 1 per cent will experience an increase of *per capita* income of approximately 2 per cent; the population with a growth rate of 3 per cent will only be able to maintain its existing levels of living.<sup>200</sup>

81. The achievement of the same developmental objective thus requires a much greater effort when the rate of population growth is higher. On the basis of varying assumptions regarding the levels of incremental capital-output ratios, the rate of population growth, and percentage increases in *per capita* income, estimates of investments have been worked out by the United Nations Economic Commission for Asia and the Far East (see

<sup>200</sup> Various simple formulae have been suggested for determining the required investments, given the increases in population and *per capita* income. Harrod, *Towards a Dynamic Economics* ... (1948, 1963 ed.), p. 28, gives the proportion of income to be saved and invested as:  $a + b + ab$ , where  $a$  indicates the investment required to maintain *per capita* output when population is increasing at a given rate, and  $b$ , the investment required to make possible a given increase in output. The term  $ab$  is, according to Harrod, small and can be neglected. Singer, "The mechanics of economic development ..." (1952), proposed the following formula:

$$D = sp - r$$

where

$D$  = growth in *per capita* income;  
 $s$  = net savings;  
 $p$  = productivity of capital;  
 $r$  = population growth.

Spengler, "Capital requirements and population growth ..." (1956), suggested the following:

$$y' = \frac{1 + as}{1 + p}$$

where

$y'$  = annual percentage rate of growth of *per capita* income;  
 $a$  = average propensity to form capital;  
 $s$  = the ratio of national income to wealth;  
 $p$  = population growth.

United Nations, Economic Commission for Asia and the Far East, "Population trends and related problems ..." (1959), includes the formula:

$$k = R[(1 + p)(1 + y) - 1] = R(p + y) + R(py)$$

where

$k$  = annual rate of capital requirements as a ratio of national income;  
 $p$  = rate of population growth;  
 $y$  = rate of desired increase in *per capita* income;  
 $R$  = incremental capital-output ratio.

In most cases, it was noted, the term  $R(py)$  can be ignored. Tabah, "Capital requirements of the developing countries ..." (1967) gave this formula:

$$I_n = \frac{1}{\lambda} \frac{R_0}{P_0} P_n e^{\varphi n} (\varphi_n + \varphi_n)$$

where

$I_n$  = investment in period  $n$ ;  
 $P_n$  = population in period  $n$ ;  
 $R_n$  = national income in period  $n$ ;  
 $\varphi_n$  = population growth in period  $n$ ;  
 $\varphi$  = rate of growth in *per capita* income;

$\frac{1}{\lambda}$  = national rate of return on investments (i.e. the inverse of capital-output ratio).

table XIII.2).<sup>201</sup> On the basis of illustrative projections of population growth and various assumptions regarding rates of growth of income, Leibenstein calculated required rates of investment.<sup>202</sup> Similar calculations were made by Tabah in order to determine the effects of declining fertility on capital requirements.<sup>203</sup>

82. An alternative, but less direct approach, for determining the investments needed to absorb the effect of population growth takes as its point of departure the stock of capital per worker, called the capital-labour ratio, and the growth of the labour force.<sup>204</sup> Given the needed capital resources per worker and the increase in the number of workers, it is possible to derive the total investment needs. Such an estimate does not necessarily coincide with that which would be obtained using the capital-output ratio and the total population as a basis, for two reasons: first, the growth of the labour force does not necessarily coincide with the rate of growth of population and, secondly, the productivity of labour may not be constant, so that a given capital-labour ratio may result in different levels of growth of income.<sup>205</sup>

83. The formulae for estimating the investments to be made on the basis of the capital-output ratio have been refined and developed into models by various writers. These refinements consist of a differentiation among different types of investments with different effects on output. Other approaches and models differentiate among sectors of the economy—mainly agriculture and non-agriculture—with different capital-output ratios. A number of these studies are mainly concerned with the needs for external financing in the developing countries and do not study in detail the effects of population growth.<sup>206</sup>

84. An important distinction has been made by Sauvy who classified investments into "demographic investments" and "economic investments" in order to differentiate between the effects of population growth and those of the desired increase of income levels on investments. Demographic investments are defined as those which are

<sup>201</sup> United Nations, Economic Commission for Asia and the Far East, "Population trends and related problems ..." (1959).

<sup>205</sup> Kurihara, *National Income and Economic Growth* (1961), p. 135, discusses the relation between the capital-output ratio, on the one hand, and the capital-labour ratio and the productivity of labour, on the other hand, giving the formula:

$$\frac{k}{y} = \frac{k}{N} \div \frac{y}{N}$$

where

$y$  = output;  
 $k$  = stock of capital;  
 $N$  = input of labour.

SOURCE: United Nations, Economic Commission for Asia and the Far East, "Population trends and related problems . . ." (1959).

required to absorb the impact of population growth, that is, those investments necessary to maintain the prevailing level of living or to make possible the same levels of consumption despite the increase of population. Economic investments are those that tend to increase the level of income. Only in a stationary population, when the economic activity rates at each age and, therefore, the size and age composition of the active population, remain constant, would all capital formation represent economic investments. Where population is growing, part of the forthcoming investments would have to be reserved for providing the increased population with the same stock of capital and, given a constant capital-output ratio, the same income. Given the level of capital formation, the higher the level of population growth, the higher would be demographic investments and the lower would be the residual left for "economic investments".<sup>207</sup>

85. Tabah, taking as a point of departure a Harrod-Domar type model and distinguishing between demographic and economic investments, shows how, given the capital-output ratio, the investment ratio as a percentage of national income is a positive function of population growth. The model also reveals in what manner the relation between increases in the level of living and those of investment, which is constant in the absence of population growth, changes when demographic investments take place and then depends on the rate of population growth. Given a constant investment ratio, population growth will exert an unfavourable influence on consumption and levels of living or, alternatively stated, the unfavourable effect on consumption and levels of living and economic investments will be lower, the lower the increase of population.<sup>208</sup>

86. A somewhat different approach giving more emphasis to the population variable is followed by Coale and Hoover who, in a model designed to evaluate the economic repercussions of a reduction in fertility with special reference to India, distinguished between investments made in equipment or those which assist directly in raising aggregate output, and those investments which serve primarily the welfare of the population and which have, as a rule, only an indirect or delayed effect on production. They subdivided the latter type of investment into those which are needed for current population and those required by the increase of population. On the basis of various assumptions concerning the relations between outlays for the population increase and those for the existing population, between the outlays for the current population and national income, and between the growth of *per capita* welfare-type outlays for the increase of population and that for the current population, they estimated the total "welfare-type" investments needed. Since the effect on output of directly productive investments, welfare-type investments benefiting the labour force and welfare-type investments benefiting the rest of the population is different, Coale and Hoover estimated the effect of each of

these investment outlays which made it possible to calculate the combined productive effects—called "equivalent growth outlays"—of these different categories. The resulting formula takes into account the effect of the rate of population growth on productive capacity through investments in equipment, tools etc. as well as the delayed or lower direct productivity of investments in the "welfare" category. The effect of these equivalent growth outlays on output was estimated by means of the capital-output ratio.<sup>209</sup>

87. The basic model for estimating the investment needs has been refined also by distinguishing between two or more sectors with differing capital-output ratios. Particularly in view of the important differences between the average and marginal capital-output ratio in the agricultural and the non-agricultural sector, as well as the changes in the share of these sectors in output and employment which occur as a result of development, a number of estimates of capital requirements have been elaborated on the basis of models which distinguish between these sectors. One of the first studies of this type, aimed at estimating the needs for external financing, provided estimates of capital needed for transferring population out of agriculture into non-farm occupations and for increasing agricultural yields. Assumptions were made, as to the transfers out of agriculture, of the amount of capital required for each person absorbed into non-agricultural employment and on this basis total capital needs were estimated. Although it was noted that population growth would absorb part of the resulting increase of income, it could not be calculated by how much this would affect the standard of living.<sup>210</sup>

88. A numerical model was used by Singer to estimate investment requirements and the growth of income. Assuming population to be distributed in a given ratio—70 to 30—between agriculture and non-agriculture and to grow at 1.25 per cent annually in both sectors, but with all natural increase in the agricultural sector being transferred to non-agricultural activities so that the agricultural population remains constant, Singer then estimated capital requirements separately for three categories of the population. They were: persons transferred from agriculture for which an estimate of capital per person (or per worker) was made; the constant agricultural population for which an estimate of income was made based on: (1) the rate of increase of production required to feed an increasing population, (2) a given increase in consumption levels and (3) a certain proportion of agricultural product to be transferred to the non-agricultural sectors; and, finally, the natural increase of the population in the non-agricultural sectors for which the desired increase of income was estimated. Assuming for these three categories of population appropriate capital-output ratios, investment requirements and the rate of increase of national income could be calculated. Singer concluded that in an economy with a low *per capita* income (around \$100), with net savings not representing more than 6 per

<sup>209</sup> Coale and Hoover, *Population Growth and Economic Development* ... (1958), chap. 17.

<sup>210</sup> United Nations, *Measures for the Economic Development* ... (1951), pp. 75-80.

cent of national income and with an over-all capital output ratio of the order of 5 to 1, no economic development would be possible if population increased at a rate of 1.25 per cent annually.<sup>211</sup> A similar analysis was presented by Spengler, who assumed the number of agricultural workers to decrease and estimated the necessary capital needed to equip new workers as well those transferred out of agriculture and to increase the capital of other workers over a certain period. He found that nearly 14 per cent of national income would have to be invested annually if population increased at 1 per cent a year and nearly 20 per cent of national income had to be invested if the population growth were 2 per cent.<sup>212</sup>

89. A mathematical model, used by Sinha with special reference to India, took into account more explicitly the effect of levels of population growth and assumed also a two-sector economy. Sinha included in his model an investment function similar to that used by Coale and Hoover; he estimated the initial and marginal saving ratios, supposing the capital-output ratio for agriculture to be constant and that for the non-agricultural sector to be either constant or increasing at a given rate. Making certain hypotheses regarding labour force growth (in particular, that the active population in agriculture would remain constant) and agricultural and non-agricultural *per capita* income, he calculated for different population projections the employment requirements as against the expected expansion of employment. Sinha thus determined capital-formation requirements as a function of labour, the growth of which he supposed would vary directly with that of population.<sup>213</sup>

90. Some analysts of the effects of population growth, while noting that the capital-output ratio does not explicitly make allowance for the contribution of labour,<sup>214</sup> have suggested the use of the Cobb-Douglas production function.<sup>215</sup> Belshaw assumed constant returns to scale and values of the product elasticities based on a number of empirical studies—0.75 for the product

elasticity of labour and 0.25 for that of capital. After establishing that in order to maintain real income per head when population and the labour force were increasing at a given identical rate, the capital stock would have to increase at the same rate as the population, he illustrated the depressive effects of increases in population and labour force, with capital remaining constant, on growth and levels of living.<sup>216</sup> Coale and Hoover used the Cobb-Douglas production function to estimate, on the basis of different population and labour projections, the future capital stock of India.<sup>217</sup> A modified Cobb-Douglas production function was also used in a model to determine, *inter alia*, the interrelations between different levels of population growth, expansion of employment, the growth of capital stock and *per capita* income as well as the corresponding average and marginal capital-output ratios. This permits the assessment, for example, of levels of demographic variables and their changes on the most important economic factors.<sup>218</sup>

91. The various models and their applications discussed above all lead to the conclusion that, given the ratio of capital accumulation, a higher population increase implies a slower growth of *per capita* income, or, conversely, that, with a higher rate of population growth, a higher rate of capital formation is required in order to maintain existing levels of living. The relative significance of a given differential in demographic growth will depend to a great extent on the capital-output ratio, or the capital-labour ratio; the higher they are, the higher the rate of capital formation required to absorb the effects of population growth.

92. The determination of the capital-output ratio, however, presents a number of problems. In the first place, the capital-output ratio is not a sharply defined concept; as a rule, it relates to net investment, although it may be applied also to gross investment. In the second place, all the problems related to the definition of capital apply equally to the capital-output ratio. The definition of capital and the capital-output ratio may or may not take into account investments in so-called "human capital" such as education, training and health, fields where investment needs are often related to demographic factors. Another source of non-comparability is that the definition of capital may be restricted to reproducible capital only, or may include, also, land and natural resources. In the third place, it has been argued that the capital-output ratio depends on the "gestation period" of the investment, which varies according to the type of investment and the degree of utilization of the equipment. Apart from these methodological aspects, the basic statistical information needed to estimate the capital coefficient is often subject to a considerable margin of error, especially in the developing countries.<sup>219</sup>

<sup>211</sup> Singer, "The mechanics of economic development . . ." (1952).

<sup>212</sup> Spengler, "Economic factors in the development . . ." (1951).

<sup>213</sup> Sinha, "Population growth and balance . . ." (1959).

<sup>214</sup> In order to take into account the contribution of labour, the use of modified capital-output ratios has been proposed. These alternative approaches incorporate assumptions as to the trends in the marginal productivity of labour different from the one implied in the conventional capital-output ratio, viz., that the marginal productivity of labour equals its average productivity. United Nations, Economic Commission for Europe, *Some Factors in the Economic Growth . . .* (1964), chap. 2, pp. 31-36; Kuznets, "Quantitative aspects of the economic growth of nations, VI . . ." (1961).

<sup>215</sup> Cobb and Douglas, "A theory of the production function" (1928); Douglas, *The Theory of Wages* (1934), chaps. 5 to 9. This function can be expressed in the following form:

$$P = b L^{\alpha} C^{\beta}$$

where

- $P$  = index of physical volume of output;
- $L$  = employed labour (in standard units);
- $C$  = employed capital (in standard units); and
- $b, \alpha, \beta$ , are constants.

Often the sum of the components  $\alpha$  and  $\beta$ —the product elasticities with respect to labour and capital—is assumed to equal unity, which means that the function is homogeneous and that an increase of  $x$  per cent of each of the two factors will also increase the product by  $x$  per cent.

<sup>219</sup> For a discussion of the several problems surrounding the estimation of the capital-output ratio and, in this connexion, capital, see United Nations, Economic Commission for Asia and the Far

(Continued on next page)

93. Probably partly as a result of these factors, estimates of capital-output ratios have varied widely.<sup>220</sup> According to Kuznets, the ratio of net capital stock to annual national income varied from about 3 to 1 to about 7 to 1.<sup>221</sup> The capital coefficients presented by Tinbergen varied from approximately 1.5 to 1 to nearly 6 to 1,<sup>222</sup> and the range of variation of the estimates of the incremental capital-output ratios presented by Higgins was even wider: 1 to 1 to about 7.5 to 1.<sup>223</sup> The problem whether the different capital-output ratios exhibit a convergence has been widely discussed. A number of writers suggest as an order of magnitude of the capital-output ratio a value of 4 to 1, which corresponds to a national income-wealth ratio of 0.25, but at the same time they recognize the tentative nature of such an estimate.<sup>224</sup>

94. Another question concerns the levels of the capital-output ratio in developed, as compared with developing countries. In general, it may be assumed that the average capital-output ratio is higher in the developed countries where capital is not scarce and capital accumulation has taken place over a long time.<sup>225</sup> More doubts exist concerning the marginal or incremental capital-output ratios in developed and developing countries. Some authors contend that in the earlier stages of development the capital needs of the developing countries are likely to be higher than at later stages,<sup>226</sup> but the majority of those writing on the subject are inclined towards the view that the marginal capital-output ratio in developing countries

is lower than in the developed countries.<sup>227</sup> Others argue, however, that it is very difficult to determine how the marginal capital-output ratios in these two groups of countries compare.<sup>228</sup> According to a number of authors, marginal capital-output ratios in industrialized countries may lie, as a rule, between 3 to 1 and 4 to 1.<sup>229</sup> Prebisch estimated a marginal capital-output ratio of 2.2 to 1 with respect to gross national product and of 2.4 to 1 for net national product in Latin America.<sup>230</sup> The average of incremental capital-output ratios for ten countries in Asia was found to be 2.5 to 1 for the period 1950-1959, but the range of variations was wide, although some low and high values of the ratio could be attributed at least in part to special circumstances.<sup>231</sup> Kuznets, on the basis of data for thirty-three countries, concluded that by and large the incremental capital-output ratios were much higher for the high income countries than for the low income countries, with a range from above 7 to 1 to between 2.5 and 3 to 1.<sup>232</sup>

95. The opinion that, as a result of the high rate of population growth in the developing countries, huge investments would be required if the growth of income were to substantially outpace the increase of population, and doubts as to the ability of these countries to attain such high rates of capital formation have frequently been expressed.<sup>233</sup> On the other hand, it has also been pointed

(Footnote 219 continued)

East, "Population trends and related problems . . ." (1959); Tinbergen, *The Design of Development* (1958), pp. 71-72; Bruton, "Contemporary theorizing on economic growth" (1960); Higgins, *Economic Development . . .* (1959), pp. 644-647; Spengler, "Capital requirements and population growth . . ." (1956); Bauer and Yamey, *The Economics of Under-developed Countries* (1957), pp. 130-131. The latter authors thought the conceptual and practical difficulties so important that they doubted whether such estimates would be useful in theory or practice.

<sup>220</sup> Some of the considerable number of estimates of capital-output ratios have been brought together, for example, in Belshaw, *Population Growth and Levels of Consumption . . .* (1956), pp. 92-96; Tabah, "Le problème population-investissement-niveau . . ." (1956); Higgins, *Economic Development . . .* (1959), pp. 22, 645, 647-649; Leibenstein, *Economic Backwardness . . .* (1957), p. 246; Oshima, "Capital-output ratios . . ." (1961); Clark, *The Conditions of Economic Progress* (1957), pp. 572-577; Tinbergen, *The Design of Development* (1958), p. 74.

<sup>221</sup> Kuznets, *Toward a Theory of Economic Growth . . .* (1965).

<sup>222</sup> Tinbergen, *The Design of Development* (1953), p. 74.

<sup>223</sup> Higgins, *Economic Development . . .* (1959), pp. 644-645.

<sup>224</sup> Clark, *The Conditions of Economic Progress* (1957), p. 570. Tabah noted that in the early 1950s a national rate of return of 0.25 or even lower was thought to be likely, but that in recent years much higher values were usually postulated. See his "Capital requirements of the developing countries . . ." (1967).

<sup>225</sup> Lewis, *The Theory of Economic Growth* (1963), p. 202, pointed out that given the average life of capital, the principal determinant of the capital-income ratio is the proportion of national income annually invested and that since the rate of accumulation is much smaller in developing countries, so would be the ratio of existing capital to income.

<sup>226</sup> Bruton, "Contemporary theorizing on economic growth" (1960); Oshima, "Capital-output-ratios . . ." (1961). These writers point in particular to the high outlays for social overhead capital needed in developing countries as the main reason for a higher incremental capital-output ratio. Other factors mentioned include: the shift towards non-agricultural activities, the increase in the size of producing units and also the process of urbanization.

<sup>227</sup> Rostow, *The Process of Economic Growth* (1960), p. 281. Some writers qualify their opinion, however: Tinbergen, *The Design of Development* (1958), pp. 13, 75-76; Hirschman, *The Strategy of Economic Development* (1958), p. 32. Most of these writers recognize the effect of the need for social overhead capital on the capital-output ratio, but suggest that a compensation operates through such factors as: the availability of natural resources, the backlog of known techniques, possibilities of using labour-intensive techniques, improved efficiency through better organization, the removal of obstacles and bottlenecks to growth and so forth.

<sup>228</sup> Lewis, *The Theory of Economic Growth* (1963), pp. 202-207. Among the arguments advanced for a higher marginal capital-output ratio in developing countries are: the inefficiency of industry; the greater waste of capital; the slower growth of technical progress. Arguments for the opposite point of view include: the availability of natural resources; the structural differences in the economy; more incentives to use less capital intensive methods of production; a more rapid growth of population. On this latter aspect see section D of this chapter.

<sup>229</sup> *Ibid.*, p. 201. However, in the period 1949 to 1959 when the countries of Europe experienced exceptionally high ratios of capital formation, the incremental capital-output ratios were in many cases above 4 to 1; United Nations, Economic Commission for Europe, *Some Factors in the Economic Growth . . .* (1964), chap. 2, p. 17.

<sup>230</sup> Prebisch, "The relationship between population growth, capital formation . . ." (1955). The Economic Commission for Latin America estimated the marginal net product-capital ratio to be between 0.40-44, similar to the estimate made by Prebisch, United Nations, Economic Commission for Latin America, *The Economic Development of Latin America . . .* (1963), pp. 17, 32-33; see also Urquidí, "Population growth and economic development in Latin America" (1967).

<sup>232</sup> Kuznets, "Quantitative aspects of the economic growth of nations, V . . ." (1960).

<sup>233</sup> Belshaw, *Population Growth and Levels of Consumption . . .* (1956), p. 185; Bruton, "Contemporary theorizing on economic growth" (1960); Spengler, "Capital requirements and population

out that the savings capacity in the developing countries is not as low as was often assumed, and that investment opportunities may to some extent create the savings necessary to carry out such projects.<sup>234</sup> In addition, in many developing countries foreign saving has been an important factor in domestic capital formation. Although the flow of capital from the more developed to the less developed countries has remained below the estimates of the needs of the developing countries,<sup>235</sup> foreign capital has contributed significantly to capital formation in these countries.<sup>236</sup> It was found that in the period 1950-1959, thirty-one of thirty-seven developing countries had received foreign savings, and in about half of all the countries this increased the domestic supply of capital from about 1 to 3 per cent of the gross domestic product.<sup>237</sup> All of the above factors may have contributed to increasing the levels of investment in the developing areas. According to one study, their increase was substantial in the 1950s: of the twenty-seven countries studied, fourteen experienced a high rate of capital formation as a percentage of gross domestic product (8 per cent or more per year); six experienced a moderate growth in investment (5-7 per cent annually); five a low growth (2-4 per cent); and two showed a decline in gross capital formation as a percentage of gross domestic product.<sup>238</sup> It has been asserted, therefore, that the situation with respect to capital formation is not necessarily as serious as is sometimes proposed.<sup>239</sup>

96. Another, more basic, question concerns the role of capital formation for economic development. Although most writers agree on the importance of capital formation for economic growth, many of them have pointed to the fact that a number of other factors, together with capital, constitute the determinants of economic growth.<sup>240</sup> Some writers have even argued that in a number of developing countries the capacity to absorb capital productively is limited, in view of the insufficiency or lack of skilled labour and qualified manpower, markets, basic facilities in transportation, communications and power, and so

growth . . ." (1956). Lewis, apparently without considering the rate of population growth, asserts, on the basis of a comparison of developing and developed countries, that savings should increase from about 5 to 12 per cent. See his *The Theory of Economic Growth* (1963), pp. 225-226. Rostow, *The Process of Economic Growth* (1960), pp. 281-282, suggests that an increase from 5 to over 10 per cent is necessary. Such an investment, given the relatively low marginal capital-output ratio, would outstrip the likely population pressure and would yield a distinct rise in *per capita* income.

<sup>234</sup> See section A of this chapter.

<sup>235</sup> See the discussion earlier in this section on capital requirements from developed countries.

forth.<sup>241</sup> Many other writers have noted that merely a stepping up of the rate of investment does not assure an accelerated economic growth unless some of the pre-conditions for growth are present.<sup>242</sup> In more specific terms, it is argued that a growth model based on capital only, using the capital-output ratios, does not take into account the role of other resources in economic growth and thus is of limited significance.<sup>243</sup> Even if, as has been frequently noted, capital and income have shown a tendency to increase at about the same rate and the average capital-output ratio, at least in the more developed countries, appears to have been relatively constant over long periods,<sup>244</sup> a number of concrete findings suggest, in fact, that capital accumulation does not exercise a predominant influence on economic growth<sup>245</sup> and that its association with the rate of economic growth is frequently relatively weak.<sup>246</sup>

97. The use of the capital-output ratio in the study of economic growth provides an over-simplistic picture of that process both in the sense that such an approach does not take into account explicitly the effect of other factors, and that the evidence as to the exact interrelation between growth of capital and growth of product is less than convincing. Nevertheless, even those who recognize these limitations usually agree that a given rate of capital accumulation, even though not a sufficient condition, is necessary for economic growth and that the higher the required investments, the higher the rate of population growth.

#### (b) Population growth and incentives to investment

98. Apart from its implications for the required level of capital formation, population growth is also thought to be one of the factors which determine the actual level of investment, particularly that of the so-called "autonomous" investment. A great deal of controversy surrounds the concept of "autonomous" investment and its counterpart "induced" investment, but in general it may be said that while the latter refers to investment stimulated by or functionally related to the economy's increase in output or income, and—according to some writers—also to such related factors as sales and profits, autonomous investment is interpreted as the investment determined by

<sup>241</sup> Bauer and Yamey, *The Economics of Under-developed Countries* (1957), p. 129; Lewis, *The Theory of Economic Growth* (1963), pp. 208-209; Millikan and Rostow, *A Proposal, Key to an Effective Foreign Policy* (1957).

<sup>244</sup> Cairncross, *Factors in Economic Development* (1962), pp. 78-80, 85; Tinbergen, *The Design of Development* (1958), p. 13; Lewis, *The Theory of Economic Growth* (1963), p. 201.

<sup>245</sup> For instance, Cairncross, *Factors in Economic Development* (1962), pp. 75-78, estimated that investment had at most accounted for one fourth of the recorded rate of progress in the United Kingdom.

<sup>246</sup> Kuznets, "Quantitative aspects of the economic growth of nations, VI . . ." (1961); United Nations, Economic Commission for Europe, *Some Factors in the Economic Growth . . .* (1964). However, for different findings, see United Nations, *World Economic Survey, 1959* (1960), pp. 25-26.

factors other than income or related variables. These determinants of autonomous investments usually include, apart from technological change and the discovery and development of new resources, the growth of population.<sup>247</sup>

99. The effect of population growth on investments occupied an important place in Keynesian theory. The argument is that a large proportion of all investments in a country with a rapidly growing population goes to provide the additional capital and durable goods needed to satisfy the increasing demand for consumers' goods. Population growth would open new investment opportunities and compensate for an insufficient "effective demand". According to Keynes, it is particularly in wealthy countries, which he equates with countries with an incipient decline in population, that investments tend to be inadequate for two reasons: (a) because with higher income a smaller proportion of total income is consumed and thus a larger proportion left to be invested; and (b) because the larger capital stock in a country with higher income and lower population growth means that investment opportunities are more difficult to find.<sup>248</sup> A similar conclusion as to the negative effect of a slow or declining population growth was reached by Harrod. He developed his model distinguishing between a warranted rate of economic growth—this being the rate required for the full utilization of capital—and the natural rate of growth—defined as the rate made possible by the increase of population and technological progress. If the former exceeded the natural rate, economic growth as well as investment would slow down.<sup>249</sup>

100. Keynes's point of view as taken up and developed by some of his followers became known as the stagnation theory. The stagnation theory held that the stimulus to investment, which found its origin in the increasing needs of a growing population in the earlier stages of industrialization, had virtually disappeared in the first decades of this century owing to the low and declining levels of population growth prevailing in that period. The result was a tendency for income or employment to decline or at least to grow more slowly than before, which in turn provoked a further decline in investments.<sup>250</sup> Hansen

distinguished three constituent elements of economic progress, each of which would be capable of creating investment outlets and causing a rapid growth of capital: (a) inventions; (b) the discovery and development of new territories and resources, and (c) the growth of population. He differentiated, however, between technological progress which gave rise to intensive investment or a deepening of capital—in the sense of more capital used per unit of production—and the two other factors, which led to extensive investment or a widening of capital—capital growing *pari passu* with the increase in the output of goods. Although, in his opinion, economic expansion in much of the past had rested to a great extent on intensive investment, the nineteenth century was a unique era of extensive investment. Population growth and territorial expansion opened vast outlets for investments, but this process came to an end when population growth declined and the frontiers for new settlement disappeared. Extensive investment decreased rapidly and the opportunities for new investment were narrowing down to those created by new technology.<sup>251</sup>

101. Among the arguments used to support the stagnation thesis is the dependence of residential construction, as well as investment in overhead capital, on population growth. A fast growing population tends to bring about a shift in demand towards housing, which requires more investment than most other kinds of consumer demand. Hansen links the effect of declining population growth also to the aging of the population accompanying this process. A stationary population with a large number of old people will be characterized by a comparatively higher demand for personal services and goods which require relatively little capital.<sup>252</sup> The aging of population accompanying the decline of fertility and of population growth is thought to affect investments also negatively in a number of other ways, among them the distortion of patterns of consumption and saving in relation to investment; the decline in the efficiency of not only the workers, but also the capital equipment, since the need for renewal of the capital stock is comparatively lower; the negative effect of a declining population growth and aging on the state of mind of the *entrepreneur*; and finally, the greater danger of slumps.<sup>253</sup>

<sup>247</sup> For various interpretations and definitions of these two concepts, see Peterson, *Income, Employment and Economic Growth* (1962), pp. 119, 227-228; Higgins, *Economic Development* . . . (1959), pp. 125-126; Kurihara, *National Income and Economic Growth* (1961), p. 27; Dieterlen, *L'investissement* (1957), p. 51.

<sup>248</sup> Keynes, "Some economic consequences of a declining population" (1937); and his *The General Theory of Employment, Interest and Money* (1951), chap. 3. See also: Reddaway, *The Economics of a Declining Population* (1939), pp. 93, 105-106; Robinson, *Essays in the Theory of Employment* (1947), p. 95. For a discussion of Keynes's views, see also Hansen, *A Guide to Keynes* (1953), p. 28; Petersen, "John Maynard Keynes' theory of population . . ." (1955). Matthews discussed the stabilizing influence of population growth and technical progress in the course of the business cycle. See his *The Business Cycle* (1959), pp. 77-82, 233-237.

Higgins, "The doctrine of economic maturity" (1946); and his "The theory of increasing under-employment" (1950). For a review of the stagnation theory, see also Stassart, *Les avantages et les inconvénients économiques* . . . (1965), pp. 181-191; Higgins, *Economic Development* . . . (1959), pp. 167-168.

<sup>251</sup> Hansen, *Fiscal Policy and Business Cycles* (1941), pp. 42-45, 349-365.

<sup>252</sup> *Ibid.*, pp. 357-359. Reddaway, *The Economics of a Declining Population* (1939), pp. 96-97, noted, however, that in a stationary or declining population families would become smaller so that the number of families would continue to increase even after the population became stationary. Such an effect, however, would only be temporary.

<sup>253</sup> Reddaway, *The Economics of a Declining Population* (1939), pp. 116-119; 156-162; Daric, *Vieillesse de la population* . . . (1948), p. 32; Boverat, *Le vieillissement de la population* (1946), p. 119; Sauvy, "Social and economic consequences of the ageing . . ." (1948); Keynes, "Some economic consequences of a declining population" (1937); Higgins, "The theory of increasing underemployment" (1950), p. 273; Fisher, *The Clash of Progress and Security* (1935), p. 155.

102. The stagnation theory has been criticized by a number of writers.<sup>254</sup> Those holding a more optimistic view used various arguments; they stressed in particular the fact that expanding population was only one factor in the increase of effective demand; *per capita* income or purchasing power might be a more important factor.<sup>255</sup> Others expressed doubts as to the likelihood of a shift in demand towards goods and services that required little capital if population growth slowed down, while some stressed the importance of technological progress as a factor in inducing investment, noting that if capital should become cheaper it might replace labour, and industries with higher capital-labour ratios might expand faster.<sup>256</sup> The validity of the arguments of those supporting the stagnation thesis was also questioned on the basis of the actual experience in many developed countries. In that connexion it must be noted, however, that stagnation was not seen as inevitable even by Hansen, who observed the "nearly unbelievable" economic progress in recent periods.<sup>257</sup> Nor were Keynes or Hansen pro-natalist, they rather proposed a public policy of investment.<sup>258</sup> It might also be assumed that they recognized that any positive effect of population growth on investment would be conditioned by the availability of capital funds and that a high effective demand could not be the result of population growth when levels of living and income were very low.

103. Those who supported the stagnation thesis found evidence for it in past trends in investments. Keynes asserted that, over the period 1860 to 1913, something like half of all capital formation was required merely to maintain capital per head<sup>259</sup> and Hansen estimated percentages of 40 and 60 for Western Europe and the United States, respectively.<sup>260</sup> It was also thought that the recovery from depressions during the nineteenth century was seldom long delayed, largely because of the rapid rate of population growth and the consequent steady increase in basic needs for food and raw materials.<sup>261</sup> Kuznets's findings on the relation between capital

and population growth in the United States over a long period (1869-1955) were, however, less definite. He found that the retardation in the growth rate of capital was to some extent accounted for by a decline in the rate of growth of labour force, but also concluded that the direct contribution of the increase in numbers of workers to capital formation was quite moderate.<sup>262</sup> A study based on data for twelve developed countries over the period 1950-1958 even suggested a relationship contrary to that assumed by the stagnationists; the results suggested that, in order to attain a higher rate of economic growth, countries confronted by slow rates of expansion in the labour force could raise the share of output devoted to investment so as to compensate for the slow increase of the labour force.<sup>263</sup>

104. Despite the lack of specific evidence, the point of view is not infrequently found that a too slowly growing population, like one growing too fast, poses the problem of the lack of investment outlets and that among countries at a certain level of development, those with moderate growth of population may have a certain advantage.<sup>264</sup> Harrod was of the opinion that, in view of its importance in this context, too little attention has been given to population growth.<sup>265</sup>

#### 4. INTERNATIONAL MIGRATION AND INVESTMENT

105. To the extent that international migration affects population growth and composition, the implications for investment are similar to those discussed in tracing the effects of population growth and composition on investment in general. Nevertheless, the implications of international migration for capital formation have received special attention, not only in relation to the investment requirements springing from international movements, but especially as far as the mutual relationships between population and capital are concerned, which also gave rise to a theory of long-term cyclical movements in population and capital movements.

106. The demand for immigrants in immigrant-receiving countries is, in general, determined by the progress of settlement and the accessibility of cultivable land, by domestic natural increase, by the pace of urbanization and industrialization and by the availability of capital.<sup>266</sup> With the increase in workers due to immigration, the stock of capital would have to increase correspondingly if the amount of capital per man were to remain the same. The absorptive capacity of immigrants may also be limited by the capacity of the building industry or other overhead capital.<sup>267</sup> Although immigration may have the effect

<sup>254</sup> For a review of the discussion of the stagnation theory and criticism of it, see Ardant, "Les diables de Malthus" (1950); Brockie, "Population growth and the rate of investment" (1950); Higgins, "The theory of increasing underemployment" (1950); Sweezy, "Secular stagnation" (1943); Neisser, "The economics of a stationary population" (1944).

<sup>267</sup> Isaac, *Economics of Migration* (1947), p. 198; Lewis, *The Theory of Economic Growth* (1963), p. 362.

of depressing wages and thus lead to some replacement of capital by labour, it is often argued that the relation between labour and capital is predominantly one of co-operation.<sup>268</sup> Despite the fact that the implications of an increase in labour force resulting from immigration depend, under given conditions, on a proportionate increase in capital, this does not exclude the possibility that the new labour supply may be the cause of increased investment activities. In fact, Isaac noted that, in the period of large-scale migration and the opening up of new continents, rapid population growth provided ample opportunities for capital-widening investments.<sup>269</sup>

107. International migration may in various ways be associated with international capital movements. Immigration is often thought to constitute a gain for the country of immigration, and a loss for that of emigration, because of the migrants representing a capital asset.<sup>270</sup> However, others have argued that this advantage is questionable: the immigrants' education may not be in line with requirements, there are problems of language, adaptation and so forth.<sup>271</sup> Another effect of international migrations for capital formation, discussed in the foregoing section,<sup>272</sup> are the capital transfers made by migrants. Immigrant transfers have the same unfavourable effect on economic growth and investment in immigrant countries as capital exports in general. The effect may be reduced, however, if, for instance, such remittances serve for financing the movement of other immigrants and thus benefit the immigration countries. Likewise, remittances increase foreign currency of emigration countries and thus the purchase of export goods of immigration countries. As far as the countries of emigration are concerned, these transfers contribute to the relief of population pressures.<sup>273</sup>

108. International movements of capital have been found to be intimately related to the international movements of population, especially in the case of new countries. Capital and labour movements, the intensity of which depend on the relative levels of their remuneration, interest and wages, are likely to adapt themselves in particular to international differences in natural resources. New countries are generally characterized by an abundant supply of natural resources and a relative scarcity of labour as well as capital owing to the low rate of savings.<sup>274</sup> The relationship between capital flows and population movements is mutual: immigration requires and stimulates the inflow of capital, and likewise foreign investments may call for and cause immigration.<sup>275</sup> Immigration is also important for capital movements from abroad in that in countries of recent settlement, a rapid growth of popula-

tion would be needed to make new investments in railways, public services and social overheads profitable.<sup>276</sup>

109. This causal relation between population and capital movements has been questioned and, in particular, it has been noted that international commodity movements may be a substitute for international migration and capital movements and may give rise to the same effects as perfect mobility of all factors of production, although this may be only true if the population of the labour-short economies has become sufficiently large and industrially differentiated.<sup>277</sup> Where either capital or labour moves alone, their movements may be in opposite directions. Under present conditions, capital by itself tends to move from countries with fully developed manufacturing industries to those in the early stages of growth; labour by itself would tend to move in the opposite direction. But, in the past, the transfer of capital and labour together has been the usual case.<sup>278</sup> Evidence of such an interrelationship between population and capital movements is said to be found in the long swings in international migrations and overseas investment in the case of the United Kingdom and the United States.<sup>279</sup>

## 5. INTERNAL MIGRATION AND INVESTMENT

110. Little is known about the implications of internal migration, as a demographic phenomenon, for capital formation. Although it may be thought that the effects of migration on investments in areas of in-migration or out-migration are not unlike those caused by an increase or a decline in population respectively, this is not necessarily true. Migration may tend to increase, on balance, investment requirements since, while in areas of in-migration it will have the effect of increasing the needs for investments in housing, transportation and communication facilities, public services and so forth, its lowering effect on capital formation needs in the areas of origin is limited, in so far as capital formation in the latter cannot fall below zero.<sup>280</sup> In addition, other factors are involved which make it impossible to compare the investment implications of internal migration with those of an over-all increase or decline in population; they include the sex and age selectivity of emigrants; the different patterns of participation in economic life characteristic for migrants; and, the different requirements for capital per head and per worker in areas of out-migration and of in-migration.<sup>281</sup>

111. The investment implications of internal migration are probably most important in the case of movements from rural to urban areas. In general, the literature has focused especially on the effects of urbanization on social

<sup>268</sup> On this point, see section D of this chapter.

<sup>281</sup> On selectivity in internal migration, see chapter VI, section B.

overhead capital or investments not directly productive, such as housing, transportation, education, public services and other facilities.<sup>282</sup> Although quantitative estimates of capital requirements due to urbanization are scarce, the needs originating from this process, even excluding the directly productive investments, may be very high. In addition, it has been noted that in practice there may be a bias favouring urban over rural investments, so that the former represent a very high and probably excessive proportion of total outlays.<sup>283</sup>

112. Only little evidence is available as to the effects of the urbanization process on investment. Abraham, discussing capital formation trends in Latin America, noted a reduction in the ratio of public saving and attributed this, at least in part, to the spread of urbanization, which made for higher costs in the public sector for education, public health, other social services and transfer type payments to households.<sup>284</sup>

#### 6. DEMOGRAPHIC AND NON-DEMOGRAPHIC DETERMINANTS OF INVESTMENTS

113. The foregoing comments have emphasized the role of demographic factors in setting levels, patterns and requirements of capital formation. It is, however, a much more complicated problem to evaluate the relative importance of these demographic factors as compared with the other determinants of investment.

114. In general, there can be little doubt that the most important influence of demographic factors is that exerted on the required levels of capital formation. Even when recognizing the limitations of a simple model of the Harrod-Domar type and the difficulties encountered in practice in estimating the capital-output ratio, it can be argued that rapid population growth will create requirements for capital formation which, if not making economic growth impossible, will certainly curtail the potential increases in levels of living which would have been possible without such population growth. On the other hand, there is no evidence that high population growth and the demographic characteristics accompanying it have been associated with low economic growth or stagnation. Significant economic growth has taken place in countries characterized by high population growth and comparative low capacities of capital formulation, suggesting thus that population growth and its implications for capital

formation have not been dominant factors, though such cases may not have been typical. More generally, it is also true that it has not been disproved that economic growth under such conditions can take place only at the cost of ignoring social overhead investments and the infrastructure, or of increasing levels of unemployment or underemployment.

115. The direct influence of demographic factors on capital formation is equally elusive. The main point that emerges from the foregoing discussion is that where sufficient investment funds are available, demographic factors such as population growth and age distribution may be a direct incentive for investment. It may be doubted, however, whether the predictions implicit in the "stagnation theory" would have held good in the more developed countries even if population growth had declined as consistently or had turned negative as foreseen by some of the writers concerned. Recent experience in the developed countries suggests that, even with relatively low rates of population growth, no lack of investment opportunities exists.

116. It may be concluded, then, that although there are many reasons to expect demographic factors to affect capital formation needs, levels and patterns, little evidence is available as to how these factors compare with other variables and what their relative importance is. On the other hand, the importance assigned to demographic factors in determining levels and patterns of investments depends to a great extent on the degree to which these forces of investment can be controlled. Investment requirements arising from population growth and other demographic factors play a significant role in determining actual investment patterns in the centrally planned economies.

#### C. Demographic aspects of employment

117. The influence of population factors and trends discussed so far in this chapter are those which affect the productive capacity of the economy through the supply of, and the demand for, capital. While there is a close relation between the level of investment and growth in output, the latter depends also on the degree to which the potential productive capacity of human, as well as material, resources is utilized. If, as may be the case, the labour force is not necessarily fully employed, the analysis must be extended in order to consider the role of demographic factors in setting the levels of employment.<sup>285</sup>

118. Employment and unemployment are complex phenomena, the definition and measurement of which give rise to a great number of problems. Some of these difficulties are related to the different concepts of employment, others to its measurement. The definition of employment in economic theory is often implied rather than explicitly stated and refers to the labour, expressed in some standard unit, taking part in the production

<sup>282</sup> United Nations, Economic Commission for Latin America, *Urbanization in Latin America* ... (1963), pp. 36-37. Oshima, "A strategy for Asian development" (1962), stressed the speculation in real estate in urban areas which absorbs investment funds which otherwise might be available for more useful purposes. Grossman, "Some current trends in Soviet capital formation" (1955), suggests a formula for estimating the investment requirements, excluding the directly productive investment, for an additional worker.

<sup>283</sup> United Nations, Economic Commission for Latin America, "Creation of employment opportunities ..." (1961). United Nations, *Report on the World Social Situation* ... (1957), p. 129, notes the heavier task of the developing countries, as compared with the now developed countries in their early stages of development, since the standards of urban overheads are much higher now than in the past.

<sup>284</sup> Abraham, "Saving patterns in Latin America" (1964), recognized that many of these expenditures were capital outlays, but added that they originated further current expenses for staffing, maintenance and so forth.

<sup>285</sup> The effects which demographic and other factors have on the supply of labour are discussed in chapter IX. Also included there is a discussion of the implications levels of employment may have on the supply of labour.

process; this definition offers many problems in its practical implications. Determining employment in this sense as an input raises the question of measuring labour in terms of time worked and homogeneous units as regards skills, aptitudes, application and so forth.<sup>286</sup> In general usage, the term employment has a broader meaning and is understood to refer to the number of persons employed out of the total labour force, i. e. including also the unemployed.<sup>287</sup>

119. It is in this context that the concept of full employment is used, meaning that every person who desires to work will actually find employment or, alternatively, as a situation in which no involuntary unemployment exists. The attainment of full employment in this absolute sense is possible only if both the economy and labour supply are in a stationary state, or the entire labour force is assured of work through a completely planned system of production. In the absence of these conditions of a stationary state, or perfect planning, a changing labour supply and economy will inevitably result in a certain amount of temporary unemployment and the existence of some "frictional unemployment", essential to provide some margin for change and adaptability of the labour force and the economy, is generally considered to be consistent with full employment.<sup>288</sup> Socialist authors contend that

unemployment is characteristic of the capitalist system, but that in the socialist countries, where the right to work has been established, unemployment has been eliminated.<sup>289</sup> Nevertheless even in these countries it has been recognized that the release and absorption of manpower may not coincide in time, place and number.<sup>290</sup> The level of frictional unemployment consistent with full employment depends upon such factors as the rate of technological change, the organization of the employment market, the occupational and spatial mobility of labour, but frequently predominant is the society's attitude towards employment which determines what level of frictional and other unemployment is thought to be acceptable.<sup>291</sup>

120. A distinction between different types of unemployment not only contributes to a better understanding of the employment problem, but is also important in the present context in so far as demographic factors may have different consequences for different types of unemployment. Apart from frictional unemployment, the following types were distinguished in an earlier chapter:<sup>292</sup> (a) seasonal unemployment, caused by more or less regular variations in the levels of activity of certain sectors or industries during given periods of the year; (b) cyclical

<sup>286</sup> International Labour Office, *Methods of Labour Productivity Statistics* ... (1951), pp. 30-42. On the need to measure labour input in terms of the time worked and the quality and effort of the labour force, see Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 27-32; Adelman, *Theories of Economic Growth and Development* (1961), pp. 10-12; Bruton, *Principles of Development Economics* (1965), pp. 15-16. Keynes, *The General Theory of Employment, Interest and Money* (1951), p. 41, measured the volume of employment by taking an hour's employment of ordinary labour as the basic unit and weighting an hour's special labour in proportion to its remuneration. Kendrick, *Productivity Trends in the United States* (1961); Denison, *The Sources of Economic Growth in the United States* ... (1962); and his *Why Growth Rates Differ* ... (1967), adjusted the labour force estimates in order to make allowance for differences in the quality of labour. For a combination of different concepts of labour at different stages of analysis, see United Nations, Economic Commission for Europe, *Some Factors in the Economic Growth* ... (1964).

<sup>287</sup> For a discussion of employment in this sense and problems of its measurement, see chapter IX. Steiner, "The productivity ratio ..." (1950), noted that the aggregate measure of man-hours, measuring employment in the economic sense, although closely associated, is not identical with the socio-economic concept of employment, which is the number of persons employed. See also Raj, *Employment Aspects of Planning* ... (1957), pp. 4-7.

<sup>288</sup> Pierson, *Full Employment* (1941), pp. 29-26; Beveridge, *Full Employment in a Free Society* (1945), pp. 19-20; International Labour Office, *Public Investment and Full Employment* (1946), p. 346; Robinson, *Essays in the Theory of Employment* (1947), pp. 21, 41-43; Lerner, *Economics of Employment* (1951), p. 17; Barrère, *Théorie économique et impulsion keynésienne* (1952), pp. 71-72; Casselman, *Economics of Employment and Unemployment* (1955), p. 10; Peterson, *Income, Employment and Economic Growth* (1962), pp. 94-95. Full employment has been defined as "a state of affairs in which a person available for and seeking work has a good expectation of finding in a short time, a job which, in the circumstances and by the standards customarily applied in the country concerned, would be considered suitable by a reasonable man". International Labour Office, *Employment and Economic Growth* (1964), p. 7. Other definitions of full employment, however, have been used. Beveridge defined full employment as a situation in which there are more vacant jobs than unemployed persons. Others have defined it as that level of employment at which a further addition to the demand for labour would result in inflationary tendencies or where aggregate

employment is inelastic in response to an increase in effective demand. See Keynes, *The General Theory of Employment, Interest and Money* (1951), pp. 15-16, 306; Lerner, *Economics of Employment* (1951), p. 23; United Nations, *National and International Measures for Full Employment* ... (1949), p. 13. See also Robinson, *Essays in the Theory of Employment* (1947), pp. 7-9. On the difficulties of defining full employment, see Rees, "The meaning and measurement of full employment" (1957).

<sup>289</sup> Academy of Sciences of the USSR, Institute of Economics, *Political Economy* (1957), pp. 566-588. Pierson, *Full Employment* (1941), p. 97. See also International Labour Office, *Employment Problems and Policies* (1960), p. 12.

<sup>290</sup> Orlov in *Nauchnye doklady Vysshei Shkoly: ekonomicheskie nauki*, No. 1 (1963). See also Kahan, "Labor turnover in the Soviet Union" (1962); and International Labour Office, *Employment and Economic Growth* (1964), pp. 18-19.

<sup>291</sup> In the socialist countries, anything above a very low rate of "labour turnover" would probably not be admissible. In most Western European countries, it is generally assumed that full employment is consistent with an unemployment rate of some 2 per cent or less, while for the United States the figure of 4 per cent is often quoted: Gordon, "Full employment as a policy goal" (1965); Phelps Brown, *The Economics of Labor* (1962), p. 116. In many cases a range of unemployment rather than a specific percentage is used. See International Labour Office, *Public Investment and Full Employment* (1946), p. 346; United Nations, *National and International Measures for Full Employment* ... (1949), p. 11; Casselman, *Economics of Employment and Unemployment* (1955), p. 11; Reboud, *Essai sur la notion de chômage structurel* ... (1964), p. 15. The levels of admissible unemployment, in addition, are not unchangeable; in an earlier study, for instance, unemployment rates varying from 3 to 8 per cent were thought to be acceptable. See Beveridge, *Full Employment in a Free Society* (1945), pp. 126-131. In many cases full employment is not specified, but rather expressions like "high and stable levels of employment" or "maximum employment" have been used. See Pierson, *Full Employment* (1941), p. 29; Casselman, *Economics of Employment and Unemployment* (1955), p. 10; International Labour Office, *Employment and Economic Growth* (1964), p. 46. Some authors have argued that, besides frictional unemployment, a certain amount of seasonal unemployment would be inevitable. Pierson, *Full Employment* (1941), p. 34; Hansen, *Economic Policy and Full Employment* (1947), pp. 19-20; United Nations, *National and International Measures for Full Employment* ... (1949), p. 13.

<sup>292</sup> See chapter IX, section E.

unemployment, which is the result of a falling off in demand of the economy due to variations in levels of activity during more extended periods; (c) structural unemployment, caused by lasting changes in the structure of the economy as a result of such factors as alterations in needs or wants, the discovery of new natural resources, or the exhaustion of existing ones, and technological progress; (d) unemployment which results from a chronic deficiency of the total demand for labour in relation to its supply.<sup>293</sup> With respect to the latter type of unemployment, basic differences exist in its underlying causes in the economically more advanced countries and those less advanced. Whereas in the former a chronic deficiency of the total demand for labour is liable to arise because of an insufficiency of the effective demand for the goods and services produced, in the less developed country this general unemployment is attributable to the shortage of capital and/or land in relation to labour, as further discussed below.

121. Emphasis on employment, not only in terms of the total number of persons employed, but also on taking into account productivity and income-producing aspects, is necessary to determine the extent to which human resources are used effectively in the production process. This latter aspect raises the problem of underemployment. The definition and measurement of underemployment again poses a number of difficulties.<sup>294</sup> Two major categories of underemployment have been distinguished: (a) visible underemployment, which involves shorter than normal periods of work and is characteristic of persons involuntarily working part-time; and (b) invisible underemployment, which is characteristic of persons whose working time is not abnormally reduced, but whose earnings are abnormally low or whose jobs do not permit full use of their capacities or skills (sometimes referred to as "disguised" unemployment) and persons who are employed in establishments or economic units whose productivity is abnormally low (sometimes called "potential" underemployment).<sup>295</sup>

# 1. POPULATION SIZE AND EMPLOYMENT

122. Since man is both a consumer and a producer, a larger population means that the demand for labour, as well as its supply, is greater than in a smaller population. The effects of the population size on employment depend mainly on the relation between population, and more specifically labour force, on the one hand, and resources and their utilization on the other.

<sup>293</sup> The terminology and classification of different types of unemployment, however, is far from uniform. For other classifications of unemployment see, among others, Reddaway, *The Economics of a Declining Population* (1939), pp. 48-53; United Nations, *Measures for the Economic Development ...* (1951), pp. 5-9; Casselman, *Economics of Employment and Unemployment* (1955), pp. 115-118; International Labour Office, *Employment Problems and Policies* (1960), pp. 4-6; Reboud, *Essai sur la notion de chômage structurel ...* (1964), pp. 17-35; International Labour Office, *Employment and Economic Growth* (1964).

<sup>294</sup> See the discussion in chapter IX, section E.

<sup>295</sup> Hsieh, "Underemployment in Asia" (1952). ## (a) Population size and cyclical unemployment

123. Any effects of the size of population, by itself, on employment appears to be the consequence of limitations due to the extent of the market, the division of labour, the lack of diversification and the dependence on international trade of the economy in so far as it is associated with population size. For instance, a low degree of diversification of economic activities may supposedly result in pronounced variations in seasonal activities and unemployment. Various writers have discussed in this connexion the argument that small populations may be characterized by a high degree of instability and a pronounced sensitivity to cyclical variations in levels of activity and employment for two reasons. With a high degree of specialization likely to be found in smaller nations, there is only a small chance of offsetting movements in other sectors and, more importantly, with a higher dependence on international trade, small nations are more likely to be affected by instability originating in other countries. However, on the whole they consider these arguments inconclusive: with few industries and a more simple economic structure, small nations are in a better position to formulate policy measures for overcoming cyclical fluctuations; in a larger economy with its more complex interrelations, a dislocation in one sector may spread through the whole economy. Statistical data for a number of developed countries suggest, in fact, that the greatest instability was found in the larger economies.<sup>296</sup>

## (b) Population size, natural resources and employment

124. A factor of considerable importance in relation to employment and underemployment is not the size of the population itself, but rather its relation to natural resources. The less than full employment of labour prevalent in economically less developed countries is, according to many authors, the result of a fundamental imbalance between population or its working contingent and the economy's natural resources, particularly land. Terms like overpopulation, or agricultural or rural overpopulation, are often used to indicate such conditions and population density, or some other variable measuring the relation between population and natural resources, is considered one of the main factors relevant to such a situation. The problem of "rural overpopulation", it is argued, is widely encountered in developing countries and particularly in densely populated peasant economies and its main manifestation is a chronic and large-scale underemployment in agriculture.<sup>297</sup> The term "disguised unemployment" in agriculture which is sometimes used to indicate this type of underemployment, concerns mainly family workers and the self-employed rather than wage labour. The typical case of such underemployment has

<sup>296</sup> Tarshis, "The size of the economy ..." (1960); Leduc and Weiler, "The size of the economy ..." (1960); Triffin, "The size of the nation and its vulnerability ..." (1960).

<sup>297</sup> Duesenberry, "Some aspects of the theory of economic development" (1950); Nurkse, *Problems of Capital Formation ...* (1953), chap. 2; International Labour Office, *The World Employment Situation* (1958); United Nations, *Report on the World Social Situation* (1957); Leibenstein, *Economic Backwardness ...* (1957), chap. 6; Ardant, *Le monde en friche* (1959), pp. 56-59.

been described as that of a number of family members working on small farms or peasant plots, contributing virtually nothing to output, but subsisting on a share of their family's income.<sup>298</sup> Underemployment, it is recognized, exists in most countries and is not limited to the agricultural sector, but it is thought to be a characteristic feature of, and to present itself on a massive scale especially in, the over-populated peasant economies where, owing to social, economic and demographic conditions, no alternative employment opportunities exist.<sup>299</sup>

125. A basic characteristic of underemployment, as noted before, is its low productivity. Many writers have gone further and identified "rural overpopulation" with a zero marginal productivity of labour, meaning that with unchanged techniques, a part of the agricultural population could be removed without reducing agricultural output significantly, if at all, or, stated in an alternative way, the same production could be obtained with a smaller labour force.<sup>300</sup> The identification of rural underemployment with a zero marginal productivity of labour led Nurkse to the formulation of his well-known proposal for the use of the excess labour in the construction of capital works. Pointing out that rural underemployment could not be absorbed by means of an expansion of monetary demand, he argued that a solution could be found by taking the labour surplus away from the land and setting it to work on capital projects such as irrigation, drainage, roads and so forth. This surplus labour, its marginal productivity being zero, could be shifted to these other capital-creating activities without affecting agricultural output and the workers could continue to be supported by their relatives. In this sense, according

to Nurkse, there exists in agricultural underemployment a hidden source of saving available for economic development.<sup>301</sup>

126. The concept of agricultural underemployment and Nurkse's proposal for using the surplus labour have been widely discussed. According to a number of writers, what is referred to as agricultural underemployment is frequently nothing else than seasonal unemployment, and the withdrawal of labour from the land without any significant changes in techniques would reduce agricultural production substantially instead of not at all or only slightly.<sup>302</sup> Nurkse, however, had already recognized that part of the disguised unemployment on the land could be seasonal, but even then, he argued, the possibility of making productive use of this labour outside the seasons of highest activity still existed. In addition, he thought that in many cases considerable unemployment existed throughout the year.<sup>303</sup> A similar view was held by Leibenstein, who distinguished between disguised unemployment that was due to the seasonal nature of agriculture, and that which would permit the removal of part of the labour force without reducing yields, that is to say where the marginal productivity of labour was zero.<sup>304</sup>

127. Other writers, critical of the theories of agricultural underemployment, have questioned the view that the marginal productivity of labour could be zero and consequently that the transfer of part of the agricultural labour force to other projects would not reduce agricultural production significantly.<sup>305</sup> It has been argued in this regard that the concept of disguised unemployment does not make allowance for the substitution of factors of production, whereas in actuality the production techniques used will tend to adapt to the relative plenty or scarcity of land and labour. Although the theory of underemployment assumes other conditions being given, Nurkse himself conceded that in order to make it possible for the surplus labour to be transferred without agricultural production being much affected, it would be necessary to introduce at least some reorganization in agri-

<sup>298</sup> Nurkse, *Problems of Capital Formation* ... (1953), p. 33.

<sup>299</sup> Nurkse, *Problems of Capital Formation* ... <sup>304</sup> Leibenstein, *Economic Backwardness* ... (1957), pp. 59-61. He also pointed out that the simultaneous existence of surplus labour and a positive income in agricultural small holdings could be theoretically explained by attributing the income to rent.

<sup>305</sup> Viner, "Some reflections on the concept of disguised unemployment" (1957); Schultz, "The role of government in promoting ..." (1956); and his *Transforming Traditional Agriculture* ... (1964), pp. 60-62; Oshima, "Underemployment in backward economies ..." (1958).

culture.<sup>306</sup> Another condition, as pointed out by Nurkse himself, for making it possible to transfer the surplus labour out of agriculture is that the population remaining behind in agriculture would not increase its consumption.

128. After the excess labour is released to work on investment projects, since production remains the same, the agricultural population will have a food surplus which, however, cannot be used for its own consumption, but is needed for feeding the labour engaged in capital formation. As Nurkse noted, there is no automatic release of the food supplies previously consumed by the underemployed and one of the main problems is to stop the peasant and his family who would remain on the land from increasing their consumption.<sup>307</sup> This is more difficult, it has been argued, because those who remain behind must work harder so that the same amount of labour can be applied.<sup>308</sup> Other problems arising from a programme for diverting excess agricultural labour to the production of capital goods relate to providing these workers with sufficient working capital, such as tools and other implements.<sup>309</sup> The diversion of this labour also involves, according to other writers, necessarily higher costs, especially so if this labour has to be employed in a locality other than its own. Under these conditions provisions for housing and transportation have to be made and incentives, in the form of additional consumer goods, are needed to make the workers leave their former work and homes.<sup>310</sup> While there is some agreement that theoretically it would be possible to use the excess agricultural labour for creating certain capital goods, these practical problems limit its application, according to a number of writers.<sup>311</sup>

<sup>306</sup> Nurkse, *Problems of Capital Formation* ... (1953), p. 33. While in this study he apparently thought such changes to be not so important, later he stated that they are "a major undertaking and cannot be lightly taken for granted". Nurkse, "Epilogue: the quest for a stabilization policy ..." (1958). See also Kao, Anshel and Eicher, "Disguised unemployment in agriculture ..." (1964); Raj, *Employment Aspects of Planning* ... (1957), p. 5; Sovani, "Underemployment, removable surplus and the saving fund" (1959); Sen, *Choice of Techniques* ... (1960), p. 5; Hsieh, "Underemployment in Asia" (1952). Sovani, "Underemployment—micro and macro—and development planning" (1955).

<sup>307</sup> Nurkse, *Problems of Capital Formation* ... (1953), pp. 36-43, noted also that the consumption of the transferred workers would remain the same. See also Vakili and Brahmananda, *Planning for an Expanding Economy* ... (1956); Sovani, "Underemployment, removable surplus and the saving fund" (1959); Abraham-Frois, *Essai sur les problèmes d'investissement* ... (1962), pp. 192-197; Buchanan and Ellis, *Approaches to Economic Development* (1955), p. 56.

<sup>308</sup> Myint, *The Economics of the Developing Countries* (1965), pp. 86-88.

<sup>309</sup> Nurkse thought that this factor would be only of minor importance. See his *Problems of Capital Formation* ... (1953), pp. 44-46.

<sup>310</sup> Buchanan and Ellis, *Approaches to Economic Development* (1955), p. 56; Lewis, *The Theory of Economic Growth* (1963), pp. 218-220; Raj, *Employment Aspects of Planning* ... (1957), p. 20; Patterson, "Impact of deficit financing ..." (1957); Clark, "Future sources of food supply ..." (1962).

<sup>311</sup> Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 56-57; Lewis, *The Theory of Economic Growth* (1963), pp. 218-220; Raj, *Employment Aspects of Planning* ... (1957), pp. 18 ff.; Balogh, "Agricultural and economic development ..." (1961), pp. 27-42; Abraham-Frois, *Essai sur les problèmes d'investissement* ... (1962), pp. 178-179.

129. A more general criticism of the theory of agricultural overpopulation concerns the assumed relation between, on the one hand, population density and, on the other, rural overpopulation or agricultural underemployment.<sup>312</sup> Population pressure or overpopulation, it is argued, cannot be measured simply by computing the number of people per unit of land. It will depend on such additional factors as climate, quality of land, water supply, the existence of mineral resources, as well as the level of technology and productivity and the available capital. The organization of agriculture and systems of land tenure are thought to be other important factors.<sup>313</sup> Some of those questioning the relation between population density and underemployment have pointed out that since this theory assumes that rural underemployment would emerge at high levels of population density, one should also expect to find high levels of employment in sparsely populated regions. However, theoretical considerations as well as empirical observations suggest that this is not necessarily so; countries not suffering from overpopulation in this sense may nevertheless have significant underemployment in agriculture.<sup>314</sup> The fact that underemployment existed in sparsely settled regions was, however, not denied by Nurkse, but he argued that while there was little disguised unemployment in the sense that, without changes in methods, a substantial part of the manpower could be diverted from food production without affecting the volume of agricultural output, underemployment existed in the sense of there being low productivity in some occupations as compared with others. The cause of such underemployment could be found mainly in differences in the supply of capital in different sectors, especially agriculture as compared to non-agriculture.<sup>315</sup>

130. Not only the theory, but also the existence and the extent of disguised unemployment has been a matter of discussion. Some of the problems involved concern the measurement of underemployment. While visible underemployment could be measured, even though incompletely, through labour force surveys, the estimation of invisible underemployment must rely on some standard of efficiency; and the most appropriate standard is difficult to determine.<sup>316</sup> Nevertheless, a considerable number of

<sup>312</sup> Clark, "What constitutes rural overpopulation?" (1955); Coale, "Population and economic development" (1963); Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 256-259.

<sup>313</sup> Myint, "An interpretation of economic backwardness" (1954), and his *The Economics of the Developing Countries* (1965), p. 31; International Labour Office, *Employment and Economic Growth* (1964), pp. 126-127.

<sup>314</sup> Boserup, *The Conditions of Agricultural Growth* ... (1965), pp. 44-45; Abraham-Frois, *Essai sur les problèmes d'investissement* ... (1962), p. 187. Myint, "An interpretation of economic backwardness" (1954), noted in more general terms that if overpopulation were a cause of economic backwardness, the question still remained why other countries not characterized by manifest overpopulation should also be backward.

<sup>315</sup> Nurkse, *Problems of Capital Formation* ... (1953), pp. 50-51.

<sup>316</sup> International Labour Office, Governing Body, *Report of the Meeting of Experts on Measurement of Underemployment* ... (1964); International Labour Office, *Employment and Economic Growth* (1964), pp. 25-28. Moore, *Economic Demography of Eastern and Southern Europe* (1945), was one of the first to use the method of a standard of productivity for measuring underemployment, but

(Continued on next page)

estimates of agricultural underemployment, though often based on criteria which were not well defined, have been made in the course of time. According to Nurkse, the problem of rural overpopulation, which was a characteristic feature of the densely populated peasant economies that stretch all the way from South-eastern Europe to South-East Asia, might be associated with disguised unemployment varying between some 15 to 30 per cent of the agricultural population.<sup>317</sup> Among the first specific estimates were those for eastern and southern European countries in the pre-war period, where estimates of the surplus from population varied from about one quarter to one third.<sup>318</sup> Higher estimates, up to 50 per cent, were given for the case of Egypt.<sup>319</sup> Available estimates for more recent periods tend to confirm the existence of high levels of underemployment in the agricultural sector of many of the densely populated countries in Asia.<sup>320</sup> Data for countries and areas in this region, including Ceylon, India, Pakistan, the Philippines, Java and Madura, and others, suggest underemployment in rural areas varying from one fifth to one third of the agricultural population.<sup>321</sup> Others contend, however, that the evidence as to the prevalence of disguised unemployment is less than convincing.<sup>322</sup> Some of the findings to the contrary were indirect, based on the relation between rural density and the development of agricultural productivity, while others were more direct. On the basis of data for more than twenty countries, Barter concluded that although rural density tended to be higher in less developed

than in more developed economies, this was not only caused by a shortage of land, but also by systems of land tenure, lack of capital and machinery etc.<sup>323</sup> Clark, on the basis of data for twenty-six countries on the number of persons engaged per square kilometre of land and the value of agricultural production per person engaged, found little relation, if any, between density and average agricultural product per head.<sup>324</sup>

131. Schultz discussed some cases in Latin America where the withdrawal of labour from agriculture reportedly resulted in a drop of agricultural production.<sup>325</sup> In a later study he analysed the effects of the influenza epidemic in India in 1918-1919 on agricultural production and concluded that the deaths caused by it, which reduced the labour force in agriculture by an estimated 8 per cent, caused a considerable decline in the acreage sown in crops and a decline in agricultural production of 3.3 per cent in the following year. He concluded from these findings that the assumption of a zero marginal productivity of labour cannot be maintained.<sup>326</sup> Kao, Anschel and Eicher, reviewing findings on disguised unemployment from five studies, concluded that there was "little reliable empirical evidence to support the existence of more than token (around 5 per cent) disguised unemployment as defined by a zero marginal product of labour and the condition of *ceteris paribus*".<sup>327</sup>

(Footnote 316 continued)

this method has been criticized by a number of writers. See Warriner, "Land reform and economic development" (1964). On the difficulties of determining the labour force which, in principle, could be removed from the land, see Sovani, "Underemployment—micro and macro—and development planning" (1955); Mathur, "The anatomy of disguised unemployment" (1964).

## 2. AGE DISTRIBUTION AND EMPLOYMENT

132. Given the different propensities to work of persons at different ages, the amount of labour forthcoming from a given population depends to a considerable extent on its age distribution. Assuming that other factors of production and levels of technology remain unchanged, the age distribution may, through its effect on labour supply, exert an influence on the levels of employment. An increase in the share of adults in the total population will, *ceteris paribus*, tend to increase labour supply more than demand, whereas an increase in the relative share of the population in inactive ages will tend to have the opposite effect.<sup>328</sup> Apart from this indirect effect which the age distribution may have on employment through the supply of labour, age has been found to be an important factor in the incidence of unemployment and significant differentials in employment levels and types of unemployment exist for different age groups, affecting in particular the younger and older workers.

<sup>323</sup> Barter, "Fundamental factors affecting the stage and status ..." (1955).

<sup>324</sup> Clark, "Population growth and living standards" (1953).

<sup>325</sup> Schultz, "The role of government in promoting ..." (1956).

<sup>326</sup> Schultz, *Transforming Traditional Agriculture* ... (1964), pp. 63-70.

<sup>327</sup> Kao, Anschel and Eicher, "Disguised unemployment in agriculture ..." (1964).

<sup>328</sup> Kaufmann, *Die Überalterung: Ursachen, Verlauf, wirtschaftliche* ... (1960), p. 357.

(a) *The age distribution and frictional unemployment*

133. A nearly universal characteristic of employment conditions are the comparatively high unemployment rates found among young workers. Factors such as lack of experience, skills, knowledge of employment opportunities and seniority are to a great extent responsible for this phenomenon.<sup>329</sup> However, much of the higher unemployment in these ages is only frictional. Among the reasons advanced why frictional unemployment may be higher among the young is the fact that these workers are mainly new entrants into the labour force. After entering into the working population some time may elapse before the young worker finds employment and while he often accepts the first available job, he is likely to later change positions, reporting brief periods of unemployment, until he finds the job he prefers. The higher mobility characteristic of the young workers is thus likely to be associated with higher frictional unemployment.<sup>330</sup>

(b) *The age distribution and structural unemployment*

134. Much of the discussion on the effects of age and the age distribution on employment has centred on the problem of the mobility of labour and its adaptability to structural changes taking place in the economy.<sup>331</sup> The view is generally found that younger workers have higher occupational and geographical mobility; older workers are less adaptable, less able to change occupations and more reluctant to move to other places, as compared with young workers.<sup>332</sup> Older workers having acquired specialized skills and experience often lack sufficient incentives to change occupations or cannot easily be retrained for other jobs requiring different qualifications.<sup>333</sup> Structural

<sup>329</sup> Reddaway, *The Economics of a Declining Population* (1939), p. 52; Kaufmann, *Die Überalterung: Ursachen, Verlauf, wirtschaftliche ...* (1960), pp. 387-389; Bloch and Praderie, *La population active dans les pays développés* (1966), p. 193. The latter authors noted that these factors might explain the higher unemployment of young workers in periods of depression.

<sup>330</sup> Casselman, *Economics of Employment and Unemployment* (1955), p. 127; Hauser, "Differential unemployment and characteristics of the unemployed ..." (1957); Bancroft, *The American Labor Force ...* (1958), pp. 8-9. It has been noted also that many young people who continue studying often look for work for short periods, or on a part-time basis—a circumstance which, because of repeated entries and withdrawals from the labour force, tends to be associated with high levels of frictional unemployment. See, for example, Bloch and Praderie, *La population active dans les pays développés* (1966), p. 193.

changes in the economy, which would require such occupational transfers, tend, furthermore, to be more favourable to younger workers, in so far as the mechanization of industry implies a larger emphasis on youth and speed than on skill and experience.<sup>334</sup> Studies of the industrial mobility of the labour force suggest that young workers entering the labour force make a greater contribution to the readjustment of labour between industries than that which results from the transfer of adults and aged workers.<sup>335</sup> The available evidence also suggests that younger people are more likely to migrate from one area to another than older people.<sup>336</sup> This being the case, the geographic readjustment to structural changes is probably more easily achieved when the labour force is composed of a relatively large proportion of young workers. It has been found in studies of labour migration that for a given economic incentive young people respond more frequently and more quickly than older persons.<sup>337</sup>

135. It has also been noted, however, that the argument of the lack of mobility of older workers can be easily exaggerated.<sup>338</sup> Moreover, under certain conditions, such as in the case of contracting industries, a high proportion of aged workers may reduce unemployment, since an outflow of retiring workers may automatically reduce the number of workers engaged in the industry, without need for dismissals such as would have been the case with a younger work force. Other views attribute the higher unemployment found among older workers not so much to a lack of mobility, but to biological factors involved in aging, or to discriminatory practices on the part of employers.<sup>339</sup> It has also been argued that the higher incidence of unemployment in these ages is not so much the result of the higher risk of becoming unemployed, but of the fact that once workers lose their jobs, they face much more difficulty in finding other employment.<sup>340</sup>

<sup>334</sup> Casselman, *Economics of Employment and Unemployment* (1955), p. 41. Durand, *The Labor Force in the United States, 1890-1960* (1948), p. 113, argues that because of the introduction of labour-saving machinery, the decrease in the demand for older workers contributed also to their comparatively high unemployment rates in periods of depression.

unemployment. The general view is that the risks of structural maladjustments are likely to be greater under conditions of a stationary or declining population than when the population is growing rapidly. Various reasons have been advanced why this is so. In the first place, it is asserted, a slowly growing population, as compared to one increasing more rapidly, will make the economy less flexible, especially in so far as an adaptation to structural changes, characteristic of virtually every economy, are concerned. A low rate of population growth signifies a smaller number of new entrants into the labour market, who are the most mobile and most adaptable to industrial and occupational shifts. It is more difficult to induce necessary redistributions of workers if it involves changes in occupation of people who have already been trained and are working with certain skills.<sup>357</sup> In the second place, it is argued that the possibility of over-development of certain industries is greater when a population is stationary or near stationary than when population is growing rapidly. As long as population grows rapidly, over-production in any line of economic activity is likely to be overcome in a relatively short period, since, in addition to normal depreciation and increase of income, population growth can correct errors in investment. With a stationary or diminishing population, however, over-expansion is not easily remedied and, under such conditions, a dislocation in the market and unemployment are likely to occur.<sup>358</sup>

143. Some authors have argued, in addition, that shifts in demand requiring changes in the structure in production may take place more frequently in a stationary or declining population. The reasoning is that such a population will consume a relatively large proportion of luxury and semi-luxury goods, the demand for which is relatively unstable and variable.<sup>359</sup> On the other hand, the importance of a slowly growing, stationary or declining population as a determinant of structural unemployment should not be exaggerated. Although population growth may be important in this respect, the experience of most developed countries has shown that a slow rate of population growth and a continuous process of change in the economic structure can be associated with high levels of employment.<sup>360</sup>

### (c) Population growth and chronic unemployment in less developed countries

144. A great deal of attention has been devoted in the existing literature to the effects population growth may have on the long-term chronic or general unemployment which results from a persistent failure of the demand for labour to absorb the existing supply. In the writings on this subject, a distinction is customarily made between the effects population trends may have on the unemployment of this type in the economically more advanced countries and those less advanced. In the former, where, as a rule, population is increasing relatively slowly, widespread unemployment, according to the stagnation thesis, can arise as a consequence of an insufficient effective demand for goods and services emanating precisely from a near stationary or declining population. Thus, whereas in the developed countries low or declining population growth is thought to affect unemployment through its negative effects on the demand side,<sup>361</sup> in the less developed countries high population and labour force growth are thought to be conducive to higher unemployment. In these countries, where a deficiency of demand is generally not considered a major influence in causing unemployment,<sup>362</sup> the characteristically rapid population and labour force growth may be important factors in causing a further deterioration in the often already critical imbalance between the supply of labour and that of the other factors of production.<sup>363</sup>

145. Growth in population, it is argued, implies an increase in the labour force and thus in productive capacity and potential employment, but it does not follow that, in practice, output and employment would increase proportionately to the increase in the labour force. Labour being only one factor of production, with the given technology, unemployment or underemployment would result unless the other factors of production increased *pari passu* with the labour force. In many developing countries where population and labour force are increasing rapidly, unemployment and underemployment are affecting an increasing portion of the population because of the lack of capital and land.<sup>364</sup>

<sup>361</sup> See the following subsection.

<sup>362</sup> For a different view see, however, Baran, "On the political economy of backwardness" (1952); Mellor, "The use and productivity of farm labor ..." (1963). See also Kao, Anschel and Eicher, "Disguised unemployment in agriculture ..." (1964).

<sup>363</sup> Eckaus, "The factor-proportions problem in underdeveloped areas" (1955); Navarrete and Navarrete, "La subocupación en las economías poco desarrolladas" (1951); Casselman, *Economics of Employment and Unemployment* (1955), p. 118; Leibenstein, *Economic Backwardness ...* (1957), p. 56; Ardant, *Le monde en friche* (1959), pp. 65-66; Power, "The economic framework of a theory of growth" (1958); Raj, *Employment Aspects of Planning ...* (1957), p. 18; International Labour Office, *Employment Problems and Policies* (1960), p. 6. Peterson, *Income, Employment and Economic Growth* (1962), pp. 468-469, notes that the modern economic growth theory has developed in two directions: one for the less developed countries where, apart from institutional factors, the main problem is one of a shortage of capacity, and one for the developed countries where the problem is principally one of ensuring sufficiently high levels of demand so that the production potential is fully utilized.

<sup>364</sup> United Nations, *Measures for the Economic Development ...* (1951), pp. 8, 46-47; Eckaus, "The factor proportions problem in underdeveloped areas" (1955); Bauer and Yamey, *The Economics* (Continued on next page)

146. The implications for employment of a scarcity of land have been discussed mainly in the context of a static situation of agricultural over-population in peasant economies. A labour surplus, manifesting itself in underemployment, is thought to be characteristic of many of these economies.<sup>365</sup> Further population growth under conditions of population pressure on the land will tend to increase the existing levels of underemployment through such factors as the decrease in land per worker, the need to take recourse to land of inferior quality, and the increase of fragmented or overcrowded holdings.<sup>366</sup> In the absence of a sufficiently rapid expansion of employment opportunities outside agriculture, disguised unemployment may reach a saturation point and open unemployment might appear and increase rapidly. Such a point of saturation and the spread of open unemployment under conditions of increasing population pressure on land will be reached much earlier in an agricultural economy operated by wage labour.<sup>367</sup> Where wage labour is predominant in agriculture, only as many workers as are needed for cultivation will find employment or, in more general terms, with given resources and technology, employment will be at a maximum when the level of wages, as determined by the marginal product, is equal to the minimum subsistence level. A working population beyond that number will remain unemployed or have to look for work outside agriculture.<sup>368</sup> The deterioration of employment conditions in agriculture due to an increasing pressure of population on the land is also one of the most important "push" factors in rural-urban migration. In the absence of sufficient employment opportunities in the cities, these migrations will imply the transfer of underemployment from rural to urban areas or the increase of open unemployment in the cities.<sup>369</sup>

(Footnote 364 continued)

of Underdeveloped Countries (1957), p. 74; United Nations, *Report on the World Social Situation* ... (1957), p. 102; Barre, *Economie politique*, vol. 1 ... (1961), p. 104; Reboud, *Essai sur la notion de chômage structurel* ... (1964), pp. 19-20; Coale, "Population and economic development" (1963); Meade, *A Neo-Classical Theory of Economic Growth* (1964), p. 47; Sadie, "Demographic aspects of labour supply ..." (1966).

<sup>365</sup> See the discussion above. United Nations, *Report on the World Social Situation* ... (1957), p. 103, noted that existing underemployment evidently emerged as a result of the failure in the past to create sufficient employment opportunities for an increasing population.

<sup>366</sup> Mandelbaum, *The Industrialization of Backward Areas* (1945), pp. 1-2; Ardant, *Le monde en friche* (1959), p. 58; International Labour Office, *Employment and Economic Growth* (1964), p. 126; Mathur, "The anatomy of disguised unemployment" (1964).

<sup>367</sup> Myint, *The Economics of the Developing Countries* (1965), pp. 34-35, noted that although the saturation point of population in a subsistence economy is higher than in a wage economy, the former is faced with the additional handicap of having to create employment for the larger number of the underemployed, in addition to the problems caused by the natural increase of population.

<sup>368</sup> United Nations, *Measures for the Economic Development* ... (1951), p. 7; Lewis, *The Theory of Economic Growth* (1963), pp. 326-327; Leibenstein, *Economic Backwardness* ... (1957), pp. 61-62; Abraham-Frois, *Essai sur les problèmes d'investissement* ... (1962), p. 181; Raj, *Employment Aspects of Planning* ... (1957), pp. 8-9; Myint, *The Economics of the Developing Countries* (1965), pp. 34, 140-141. To the extent that the demand for wage labour in agriculture fluctuates in the different seasons, some of this unemployment may be mainly seasonal.

<sup>369</sup> Navarrete and Navarrete, "La subocupación en las economías poco desarrolladas" (1951); Lewis, *The Theory of Economic Growth*

147. Apart from its effects on the man-land ratio, the generally high rates of labour force growth in the less developed economies tend to worsen the existing imbalance between labour and capital resources. In the view of many writers, insufficient capital formation is the crucial obstacle to creating sufficient employment opportunities.<sup>370</sup> A number of methods have been used for estimating the investment requirements to employ an increasing labour force. A simple method, discussed above,<sup>371</sup> is based on the stock of capital required per worker, the so-called capital-labour ratio. Given this ratio and the rate of growth of the labour force, total investment requirements can be estimated.<sup>372</sup> Another method is based on the Cobb-Douglas production function, which incorporates both labour and capital as factors determining the level of output.<sup>373</sup> The relations between labour force growth and investment requirements have also been considered in a number of models. Coale and Hoover used the Cobb-Douglas production function

(1963), pp. 326-327, 338; United Nations, *Report on the World Social Situation* ... (1957), p. 129; International Labour Office, *Why Labour Leaves the Land* ... (1960), p. 210; Ardant, *Le monde en friche* (1959), pp. 59-63; Myint, *The Economics of the Developing Countries* (1965), p. 89. For a general discussion of factors underlying rural-urban migrations, see chapter VI, section C.

<sup>370</sup> Capital formation is thought to be essential not only in the over-populated agricultural economy, where it is needed to create employment outside agriculture, but also in those countries where land is not scarce. In the latter, it is argued, capital formation is a basic requisite for realizing the potential development and employment opportunities existing in these areas. See Nurkse, *Problems of Capital Formation* ... (1953), pp. 50-51; Loufty, *La planification de l'économie* ... (1963), pp. 357-358, 365-366. In addition to capital needs in this connexion, the inequality in the distribution of land ownership found in many of the less densely settled countries has been stressed. International Labour Office, *Employment and Economic Growth* (1964), pp. 126-127. Coale, "Population and economic development" (1963) cites as a possible exception to the usual reasoning on investment requirements the case of a "frontier society" where labour settles on empty land and provides its own capital by clearing land, constructing roads, building houses, schools etc. In general, however, little is known about the need for capital in densely settled agricultural areas as compared with sparsely settled ones, although several writers contend that the pressure to form capital is probably less and the capacity to do so probably higher in the latter. See Spengler, "Capital requirements and population growth ..." (1956); Belshaw, *Population Growth and Levels of Consumption* ... (1956), p. 62. Anderson, "Population growth and capital requirements ..." (1955), mentions, among many factors affecting the ability to generate capital, the richness or paucity of natural resources.

<sup>371</sup> See section B of this chapter.

<sup>372</sup> Tinbergen, *The Design of Development* (1958), pp. 12-13, 71-72; Spengler, "Capital requirements and population growth ..." (1956); Cotta, *Analyse quantitative de la croissance des pays sous-développés* (1967), pp. 111-114; United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic Development* (1960), pp. 83-84; United Nations "Use of models in programming" (1961); Caire, *La planification* (1967), pp. 242-243. Denoting capital by  $C$  and employment by  $L$ , the capital-labour ratio is defined as  $C/L$ . Assuming the marginal capital-labour ratio to equal the average ratio, investment ( $I$ ) needed to employ a labour force increase ( $\Delta L$ ) is:

$$I = \frac{C}{L} \Delta L.$$

<sup>373</sup> Belshaw, *Population Growth and Levels of Consumption* ... (1956), pp. 58-66; Coale and Hoover, *Population Growth and Economic Development* ... (1958), pp. 324-327. See also section B of this chapter.

demand would cause unemployment to increase.<sup>386</sup> This argument is not basically affected, as a number of writers have pointed out, if it is admitted that, in practice, wages are often higher than the marginal product of labour. A number of reasons have been offered for this phenomenon—including such factors as the resistance of labour unions and imperfections in the labour markets. However, some writers have suggested that the levels of employment may be higher than could be expected on purely economic grounds. Lewis thinks there are traditions and a code of behaviour according to which it is good form to offer as much employment as possible.<sup>387</sup> Leibenstein and others have argued that below a certain level of wages, the efficiency of labour depends upon the wage level itself, especially through the effect the latter has on nutrition, health and the energy of the worker, and the wages offered might thus be higher than the subsistence level. Consequently, and despite the depressing influence of the surplus labour on actual wages paid, workers may be employed beyond the point where the marginal productivity of labour equals the wage level.<sup>388</sup> On balance, it appears that under conditions of a rapidly growing population and labour force the wage level, however determined, would not be flexible enough to allow for the employment of all additional workers.

151. Considerable differences of opinion exist about the feasibility and desirability of using more labour intensive techniques as opposed to more capital-intensive techniques as a means of absorbing a labour surplus.<sup>389</sup> The general argument in favour of the use of more labour-intensive methods is that the factors of production should be combined according to the relative quantities available. The level of capital formation being low in many of the developing countries, whereas labour, especially of the unskilled type, is abundant, suggests that these economies should adopt those methods of production which have a low capital and a high labour intensity.<sup>390</sup> A similar reasoning holds also, it may be noted, where land is

concerned; a scarcity of land, it is argued, calls for land-saving improvements, such as better seeds, the use of fertilizers etc. rather than for mechanization and the extensive use of land.<sup>391</sup> In general, those proposing the use of more labour-intensive methods of production thus reason that technical efficiency should not be confused with economic efficiency in a broader sense.

152. In practice, however, the room for using more labour-intensive methods of production is circumscribed by the existing technical possibilities of combining labour and the other factors of production in different manners. The lack of such possibilities is often cited as one of the major obstacles to the introduction of more labour-intensive methods of production, the more so since existing techniques having been developed primarily in the economically more advanced countries, where more often than not labour and not capital is the scarce factor, are therefore not adapted to the factor proportions typical for the less developed countries.<sup>392</sup> A more fundamental question concerning the choice of techniques is that there can be a conflict between increasing employment and income. Labour-intensive techniques, it is affirmed, involving higher labour costs, imply a lower return per unit of capital and by creating more employment result in a rise of the levels of consumption, since wages are spent nearly exclusively for consumption. More capital-intensive techniques, in contrast, may give higher returns on capital and, by yielding a higher surplus over the wage bill which can be invested, will accelerate subsequent economic growth. In sum, labour-intensive methods of production, though having the immediate effect of raising employment, may not do so in the long run, since the rate of economic growth and ultimately the expansion of employment depend to a large extent on the proportion of income invested, and the latter will be higher, as noted, the more capital-intensive the methods of production.<sup>393</sup> Various other considerations have been advanced in favour of the use of more capital-intensive methods of production, including their role in breaking with tradi-

<sup>386</sup> Bauer and Yamey, *The Economics of Under-Developed Countries* (1957), pp. 76-79; Raj, *Employment Aspects of Planning* ... On the problems of controlling consumer demand when previously unemployed persons are put to work, see: Lewis, *The Theory of Economic Growth* (1963), pp. 221-222; Duesenberry, "Some aspects of the theory of economic development" (1950); Ardant, *Le monde en friche* (1959), pp. 111-113; International Labour Office, *Employment Problems and Policies* (1960), pp. 24-25.

tional patterns and opening new horizons.<sup>394</sup> Arguments against the use of more labour-intensive techniques have mentioned that while labour may be cheap, it is also inefficient.<sup>395</sup> Nevertheless, it has been pointed out that the choice between labour-intensive or capital-intensive techniques is not absolute, but reflects, rather, the alternative between present higher consumption and employment and a future more rapid economic development and thus constitutes essentially a policy choice.<sup>396</sup>

153. On the whole, it may be said that whereas a population and labour force increasing at a high rate will require substantially larger capital outlays and other resources for creating additional employment opportunities, such a population has no intrinsic advantages for achieving higher investment. On the contrary, rapid population growth and the characteristics associated with it, particularly its age distribution, may tend to have rather the opposite effect. If, in addition, wages are at the subsistence level or, for any other reason, inelastic, and if the possibilities for the use of more labour-intensive techniques are limited, population growth is likely to be associated with deteriorating employment conditions.

(d) *Population growth and chronic unemployment in the more developed countries*

154. Unlike the situation in the less developed countries, high levels of population growth and a scarcity of co-operant factors of production are not typical of the economically more advanced countries and thus not a factor in employment problems. On the contrary, according to the stagnation thesis, the risk of chronic unemployment in these countries may increase as a result of a slow or declining population growth. This theory starts from the assumption that for an economy to operate at a high level of income and employment, savings and investment must be in equilibrium or, in other words, the rate of investment must not be too low, nor that of savings too high. If in the light of prospective earnings, *entrepreneurs* are not prepared to invest an amount equal to that which individuals desire to save, the levels of income and employment would contract through the process described earlier in this chapter.<sup>397</sup> According to Keynes, and especially those of his followers who formulated the stagnation thesis, a declining population, through a deficiency of effective demand, tends to exert a depressive effect on investment and a possible upward pressure on the propensity to save. A declining population or a lowering of its rate of growth, it was asserted, would discourage investment, since the expectations of future earnings on the part of the *entrepreneurs*, as determined by the marginal efficiency of capital, would become more pessimistic. In addition, savings might increase as a result

of the decline in the average size of the family, or at least not adapt themselves to the lower levels of investment.<sup>398</sup> As a result of the growing discrepancy between savings and investment, the process of contraction would set in, leading to a stagnation of income and the emergence of chronic unemployment.<sup>399</sup>

155. A number of arguments questioning the supposed effects of a declining population on chronic unemployment have been advanced. Most of these concern the underlying hypothesis of declining investment opportunities and increased savings and are discussed earlier in this chapter.<sup>400</sup> The importance of factors other than demographic ones in determining employment is generally acknowledged.<sup>401</sup> Even if a slow population growth might, through the mechanism described, in principle have the effect envisaged by the stagnationist writers, any such effect could be easily counteracted by the various means at the disposal of policy-makers, thus assuring full employment under conditions of economic growth.<sup>402</sup>

#### 4. INTERNATIONAL MIGRATION AND EMPLOYMENT

156. The interrelations between international migration and employment are close, but complex. On the part of the individuals who choose to migrate, that is, excluding refugees, displaced persons and others in similar categories, the predominant motivation is the expectation of better opportunities for themselves or their descendants in which employment considerations play an important role.<sup>403</sup> The actual effects of international migration on the levels of employment in both countries of destination and origin depend on a large number of factors. The fundamental question is how the demand for labour responds to the changes in supply resulting from immigration or emigration. In addition, however, immigrants and emigrants are consumers as well as producers and, potentially, immigration tends to increase the demand for consumer goods, housing and so forth

## 5. INTERNAL MIGRATION AND EMPLOYMENT

and, hence, the volume of investment and the demand for labour, while emigration has the opposite result. Unless the international migrants have sufficient financial resources of their own, this potential demand will become effective only if they are gainfully employed. The implications of international migration for employment may roughly be considered under two headings: first, the effects on the demand for labour of the over-all changes in supply brought about by the migration and, second, those due to the specific demographic and, especially, economic characteristics of the international migrants.

157. The consequences of international migration for employment are complicated not only by the particular characteristics of the migrants as regards their sex-age structure, but also by their distribution according to occupation, industry and other economic characteristics. Immigrants of working ages seeking employment offer services which are either competitive with or complementary to those of the non-migrant labour force.<sup>404</sup> Usually since international movements imply a change of employment, they may be expected to be associated with some frictional unemployment. It has also been argued that seasonal unemployment may be reduced by means of short-term migratory movements.<sup>405</sup> More important are the consequences of international migration for cyclical unemployment.<sup>406</sup>

158. As far as structural unemployment is concerned, immigration which consists in a large part of young adults may make the labour force in the country of immigration more flexible and enable it to adapt more easily to structural changes in the economy. This may be especially true in the case of countries characterized by a slow population growth.<sup>407</sup> The most immediate effect of international migration on employment, however, is the impact of immigration in countries where there exists a shortage of labour with respect to the other means of production and that of emigration from countries with a chronic excess of labour supply in relation to land or capital resources. Historically, the major migratory movements have originated in countries where in relative terms overpopulation existed and have been to countries with a scarcity of labour, thus relieving the employment problems in the countries of origin and responding to an effective demand for labour in the countries of destination. While emigration from the less developed countries might, under present conditions, have the same effect and reduce the pressure on employment, the practical feasibility of emigration from these countries on a scale sufficient to offset population growth and the deterioration in employment conditions, taking into account the volume of movement which would be required and the absorptive capacity of the countries of immigration, has been discarded by most writers.<sup>408</sup>

159. As in the case of international migration, economic motivations and employment opportunities furnish the major incentives to internal migration. The close association between internal migration and employment aspects are discussed in an earlier chapter in so far as the latter is a factor in inducing or discouraging the spatial mobility of the population within the frontiers of a nation.<sup>409</sup> Although, in the present context, the main emphasis is on the effect of migratory movements on levels of employment, this aspect cannot be considered independently of the factors which determine the migrations. Unequal economic and population growth in various parts of a country are the rule rather than the exception, and migration is the major factor in bringing about an adjustment between different regions. A certain minimum degree of mobility, therefore, is necessary for the maintenance of high levels of employment in a dynamic society.<sup>410</sup> Under ideal conditions, where the over-all demand for and the supply of labour are in equilibrium, internal migrations, in so far as they respond to employment opportunities, re-establish the geographical balance of supply and demand in different regions or areas of a country. If the mobility of labour under these conditions is less than perfect and the flow of internal migration either too small or too large, unemployment or underemployment would appear in certain areas while labour shortages would exist elsewhere.<sup>411</sup> Among the many factors determining changes in the geographic patterns of economic activities and employment, the major one is the process of industrialization. Among the most important forms of internal migration are the rural-to-urban movements which occur in response to the expansion of employment opportunities in urban areas consequent upon the geographical concentration of economic activities associated with the industrialization process. Nevertheless, there is no compelling reason for rural-urban migration to adapt itself to the existing and emerging employment opportunities, especially when there is a shortage of the over-all demand for labour in relation to its supply.

160. One of the characteristics of internal migration which has a direct repercussion on its employment implications is its age selectivity; the influence in this respect has been noted especially with respect to the high migration rate of young workers. Rural-urban migration, in particular, results, on the one hand, in a high proportion of young workers in urban populations while, on the other hand, the high degree of age selectivity implies a considerable movement of young workers

<sup>409</sup> See chapter VI.

<sup>411</sup> Migration may reduce unemployment not only by improving the distribution of labour but also by increasing the total demand for labour through the need for investment in housing, public services and transportation in the area of in-migration. Although migration also reduces investment needs in areas of out-migration, the effect is likely to be positive since investment cannot fall below zero. Baker, "Significance of population trends..." (1937); Henry, "Structure de la population..." (1949).

<sup>404</sup> For a discussion of this aspect, see chapter VII, section D.

<sup>405</sup> Spengler, "The economic effects of migration..." (1958).

<sup>406</sup> See chapter VII, section D.

out of agriculture.<sup>412</sup> While urban employment opportunities thus have to expand proportionately more rapidly than the total volume of migrants to the cities, the predominance of young workers, with their greater flexibility and adaptability, makes it comparatively easier to absorb the larger supply of labour.

161. In both developed and developing countries, lower incomes and more limited employment opportunities in agriculture are important causes of migration, but in the former, the expansion of the demand for labour in the non-agricultural sector is the major explanation for the rural-urban migration. These migrations have been important in many countries as a means of preventing structural unemployment, reducing the labour surpluses in agriculture and satisfying the expanding demand for labour in the secondary and tertiary sectors of the economy. Even so, a number of writers have pointed out that in many instances in the economically more advanced countries the amount of internal migration in absolute terms was not large enough to bring about the needed adjustment between labour supply and demand.<sup>413</sup>

162. In the economically less advanced countries, where economic development requires profound changes in the structure of the economy, internal and especially rural-urban migrations are essential to increase the supply of the non-agricultural labour force required by the industrialization process. Nevertheless, in most developing countries, the employment problems created by rural-to-urban movements reflect not so much structural factors as a chronic deficiency of the demand for labour. Low levels of incomes and productive employment in agriculture, associated with high density or high rates of population growth, are among the main determinants of the out-migration from rural areas. To the extent that these movements to the cities respond more to "push" factors existing in agriculture than to "pull" factors operating in the non-agricultural sectors, rural-urban migration in many developing countries constitutes a transfer of underemployment in agriculture to open unemployment or underemployment in the cities.<sup>414</sup> Over-urbanization in the sense that people move to cities even though economic opportunities there are quite limited is considered to be characteristic of many of these countries.<sup>415</sup>

## 6. DEMOGRAPHIC AND NON-DEMOGRAPHIC DETERMINANTS OF EMPLOYMENT

163. The role of demographic as compared with other factors in setting levels of employment cannot be stated in simple terms. The degree of employment of the existing labour force is ultimately the result of the influences of the numerous factors underlying labour supply and demand. A separate evaluation of the different factors involved in determining the supply of and the demand for labour as well as their interactions, provides a basis for some tentative conclusions.

164. Within the given socio-economic framework of a nation, demographic factors are among the main determinants of the volume, structure and growth of the labour supply and thus of that level of the demand for labour which would be required to ensure full employment. Nevertheless, although population and labour force size are interdependent, the relation between the two is not invariable. This means, in the first place, that population and the potential supply of labour do not necessarily expand or contract at the same rate. Through the interdependence between the components of demographic change and the population structure, changes in population size and growth induced by the former may affect the population structure, especially the age composition, and the resulting supply of labour. In the second place, the lack of an invariable relation between population and labour force supply reflects the influence of other than demographic factors which manifest themselves through the patterns of sex-age specific participation rates and their changes.

165. As far as the demand side is concerned, in those cases where the full utilization of human resources is a basic goal of economic policy, as it is held to be in the socialist countries, demographic factors through their influence on the supply of labour are an important factor in determining levels of employment. If, however, the level of utilization of labour force is left to the mechanism of the market, employment will depend primarily on the relative abundance or scarcity of the other factors of production. A relative scarcity of natural resources or of capital with respect to labour will, under given techniques, be associated with underemployment or open unemployment. Whereas various courses of action have been proposed to remedy the disproportion between labour and other factors of production under these circumstances, including the use of the surplus agricultural labour in the construction of capital and of more labour-intensive methods of production, the feasibility or adequacy of such measures has been widely questioned.

166. Although population size, growth and characteristics are also thought to affect frictional, cyclical and structural unemployment, and a scarcity of labour compared with other factors of production is considered to induce unemployment through a lack of effective demand, the discussion on the effects of demographic factors on employment has centred mainly on the problem of the high levels of underemployment and unemployment caused by the basic disproportion between the supply of labour and that of other factors of production in the developing countries and the deteriorating effect of con-

tinued high population growth on employment conditions. The solution to these problems through reducing the pressure of population, both in a static and dynamic sense, and through increasing the capacity of the economy to absorb the supply of labour cannot, however, be considered only from the restricted perspective of employment. Involved in it is the whole problem of economic progress and development of the economically less advanced countries.

#### D. Demographic aspects of productivity

167. The preceding sections of this chapter have considered the role of demographic factors in determining the required and actual levels of capital formation and the degree of utilization of the labour force, assuming in most cases that productivity and, in more general terms, the performance of the economy as a whole are as given. The purpose of this section is to discuss the influence, direct or indirect, of demographic factors on productivity and the level of development and progress of the economy, taking into account the other determinants of economic change discussed in earlier sections.

168. The concept of productivity may have different meanings. In its broadest sense, it is an index of the efficiency of the economy as a whole or of any of its segments and thus reflects all factors affecting the working of the economy and its parts. Definitions of productivity usually focus, however, on the relation between what the economy produces and what is needed to obtain this production in terms of the factors entering into the production process. Productivity in general is defined as the ratio between output or production, on the one hand, and the input or resources used in achieving this production, on the other.<sup>416</sup> In addition, to this over-all measure, ratios of output to particular inputs, sometimes referred to as partial productivity, can be calculated. In principle, these ratios could be obtained for each of the inputs, but the one which is most widely used, and which has come to be considered as a general measure of the efficiency of the economy, is labour productivity.<sup>417</sup> The use of the output-labour ratio, in its various forms, as a measure of such productivity, while widespread, has also been criticized for a number of reasons. The labour productivity ratio, it is asserted, suggests implicitly that production can be wholly attributed to labour, while in fact the ratio reflects everything that affects the level of

output and the volume of employment. Moreover, since the composition of inputs and outputs can vary, changes in the output-labour ratio could occur—if, for instance, labour is substituted for capital or vice versa, or if the production of goods with differing factor combinations would expand at different rates—in the absence of improvements in efficiency.<sup>418</sup>

169. However, a number of factors plead in favour of the use of the labour-productivity concept as a measure of productivity. Even some of those writers who argue that productive power, as the result of the combined use of all factors that co-operate in production, should be related to the combined input of them, concede the great difficulties inherent in determining and measuring all these factors.<sup>419</sup> In addition, if any factor is to be singled out, labour appears to be most appropriate, considering the relative ease with which it can be measured, the central position of labour in the production process and its nearly universal use in the production of goods and services.<sup>420</sup> Provided, it is argued, that labour productivity is not interpreted as reflecting the intrinsic efficiency of labour, but rather the effectiveness with which labour is used in conjunction with other factors, it is an adequate, if not completely satisfactory, measure of productivity. Labour productivity is thought to be significant for another reason. A number of writers have argued that productivity in general, as an index of the efficiency with which resources are converted into goods and services, can be considered as a measure of economic progress.<sup>421</sup> In the case of labour productivity, these two aspects are intimately related, since man is both means and end in production, and output per worker and *per capita* income, as an indicator of levels of living, are very closely associated.<sup>422</sup>

<sup>418</sup> Zobel, "On the measurement of ..." (1950); Steiner, "The productivity ratio ..." (1950); Davis, "The meaning and measurement of productivity" (1951); Mehta, *Measurement of Industrial Productivity* (1955), pp. 13, 15; Siegel, "Considérations sur la mesure de la productivité ..." (1955); Kendrick, *Productivity Trends in the United States* (1961), p. 7; Stigler, "Economic problems in measuring ..." (1961); Fabricant, *Basic Facts on Productivity Change* (1959).

<sup>419</sup> Davis, "The meaning and measurement of productivity" (1951); Siegel, "Considérations sur la mesure de la productivité ..." (1955); Rostas, "Les différents concepts de la productivité" (1955); Mehta, *Measurement of Industrial Productivity* (1955), pp. 17-19; Fabricant, *Basic Facts on Productivity Change* (1959), p. 6.

<sup>420</sup> Rostas, "Les différents concepts de la productivité" (1955); Mehta, *Measurement of Industrial Productivity* (1955), p. 12; Fabricant, *Basic Facts on Productivity Change* (1959), p. 6; Kendrick, *Productivity Trends in the United States* (1961), p. 7; Stigler, "Economic problems in measuring ..." (1961); International Labour Office, *Measuring Labour Productivity* (1969), pp. 12-13. Holding that the value of a commodity is the social labour embodied in it, Marxist writers consider only labour productivity, defined as the amount of product created in a given unit of labour-time, as pertinent. See, for instance, Academy of Sciences of the USSR, Institute of Economics, *Political Economy* (1957), pp. 71-76.

<sup>421</sup> Clark, *The Conditions of Economic Progress* (1957); Bell, *Productivity, Wages and National Income* (1940); Davis, *The Industrial Study of Economic Progress* (1947); Steiner, "The productivity ratio ..." (1950).

<sup>422</sup> Rostas, "Les différents concepts de la productivité" (1955). Boulding, "Difficulties in the concept of an economic unit" (1963), noted that if a constant ratio between labour input and population existed, labour productivity and *per capita* income would vary in exactly the same proportion.

<sup>416</sup> Young, "The productivity of labour in manufacturing" (1947); International Labour Office, *Methods of Labour Productivity Statistics* ... (1951), p. 6; Davis, "The meaning and measurement of productivity" (1951); Siegel, *Concepts and Measurements of Production and Productivity* (1952); and his "Considérations sur la mesure de la productivité ..." (1955); Kendrick, *Productivity Trends in the United States* (1961), p. 6; Fabricant, *Basic Facts on Productivity Change* (1959), p. 6; International Labour Office, *Measuring Labour Productivity* (1969), p. 11.

<sup>417</sup> Young, "The productivity of labor in manufacturing" (1947); Steiner "The productivity ratio ..." (1950); Mehta, *Measurement of Industrial Productivity* (1955); Fourastié, *Le grand espoir du XX<sup>e</sup> siècle* ... (1949), pp. 16-21; Fabricant, *Basic Facts on Productivity Change* (1959), p. 6; Kendrick, *Productivity Trends in the United States* (1961), p. 6; International Labour Office, *Measuring Labour Productivity* (1969), p. 12.

170. The actual measurement of labour productivity is not without its problems. The labour productivity ratio can be determined in a number of ways, but the basic distinction is that between physical and value measurements. In the former, output is expressed in terms of homogeneous physical units of product, such as weight, volume etc. Such measures can evidently be obtained only for one product or group of similar products, and productivity in the sense of the performance of the economy as a whole, which is the most relevant in the present context, has to be based on the value of the output. In this case output can be evaluated either by using price series or by multiplying physical quantities by a series of value weights, both of which have certain drawbacks. Likewise, in the determination of the labour input a number of problems arise—such as that of the heterogeneity of labour—to which as yet no completely satisfactory answer has been found.<sup>423</sup>

171. Labour productivity, as a general measure of productivity, even though reflecting economic efficiency and progress, does not explain or specify the factors and components of productivity change. Since, as noted before, the latter is influenced by any factor apart from labour which affects output and employment, its underlying determinants are numerous and elude a simple classification.<sup>424</sup> As far as the more immediate determinants are concerned, and excluding the effects of changes in the composition of input or output, productive efficiency is thought to be affected especially by technological innovation, changes in the scale of output, changes in the rate of utilization of capacity and changes in the input of “intangible capital” designed to increase the quality of the input of tangible factors.<sup>425</sup> Among these factors, the role of technological progress has received special attention. Few economists doubt that technological progress in the sense of the application of empirical science and knowledge to the production of goods and services, assuming thus also the necessary attitudes and incentives, has been and continues to be the central factor in economic growth and progress.

172. Demographic factors may influence productivity in a number of ways, although, partly due to the complex nature of the productivity concept itself, these effects appear to be more elusive and less known than in the case of capital formation or employment. Nevertheless, the increased interest in recent years in economic progress and productivity, in the context of the progressive emphasis on economic development and growth and the importance of their non-tangible determinants, has also contributed to a further exploration of the implications

of demographic factors for productivity. Among the aspects which have been considered in this relation are the effects of population size, trends and characteristics on factor-proportions and the methods of production, on the composition and structure of the economy and its output, on specialization and economies of scale, as well as on the adaptability to changes of the economy, and on innovations and technological progress.

# 1. POPULATION SIZE AND PRODUCTIVITY

173. The importance of the size of the population for productivity has been discussed by many authors, but no unanimity exists as to its actual significance. In part, this is due to the fact that while the size of the population itself has certain implications for productivity, other factors—such as the geographical size of the country or its income—thought to be closely, but not necessarily, associated with the size of the population, tend also to be interrelated with the productivity of the economy. The complexity of the problem derives to a great extent from these interrelations between the size of the population and other indices of the size of the country, but also reflects the various ways in which population size may affect productivity. Population size may be said to influence productivity mainly through the diversification and specialization of the economy, the size of the market, the importance of foreign trade and, in relative terms, the ratio of the population to natural resources. Since neither the effects of the one, nor of the other of these factors have as yet been completely identified and ascertained, their combined influence on productivity still remains to be determined.

## (a) Population size and economies of scale

174. There is no unanimity as to the nature and importance of economies of scale. In general, they are related to the question of the relative advantages or disadvantages which can result from the scale of production and operation of the economy as a whole or of any of its segments. More specifically, economies of scale are concerned with the effects of an increase in output consequent on the increase of inputs or, alternatively stated, economies of scale exist when a proportionate increase in inputs generates a greater than proportionate increase in output. In the discussion of the effects of the scale of production, a distinction is frequently made between internal and external economies. Internal economies may be described as those secured within the firm or plant, whereas external economies are defined as those which benefit the firm through the general development of the industry or the economy.<sup>426</sup> Nevertheless, the difference between the two is not always clear. What are internal economies in one firm may be external in another, and vice versa.<sup>427</sup>

<sup>423</sup> International Labour Office, *Methods of Labour Productivity Statistics* ... (1951), pp. 6-15, 30-42; ———, *Measuring Labour Productivity* (1969), pp. 15-36; Fourastié, *Le grand espoir du XX<sup>e</sup> siècle* ... (1949), pp. 16-21; and his *La productivité* (1957).

<sup>424</sup> For a list of factors determining productivity, see International Labour Office, *Methods of Labour Productivity Statistics* ... (1951), p. 18; ———, *Measuring Labour Productivity* (1969), pp. 13-14. Some 37 factors classified as general, organization and technical factors and human factors are given. For another list, see also Zobel, “On the measurement of ...” (1950).

<sup>425</sup> See, for instance, Kendrick, *Productivity Trends in the United States* (1961), p. 11; Denison, *Why Growth Rates Differ* ... (1967), pp. 9-10.

<sup>426</sup> Marshall, *Principles of Economics* (1890, 1961 ed.), pp. 266, 314; Stigler, *Production and Distribution Theories* (1941), p. 69; Marcy, “How far can foreign trade and customs agreements ...?” (1960); Leibenstein, *Economic Backwardness* ... (1957), p. 106; Belshaw, *Population Growth and Levels of Consumption* ... (1956), pp. 67 ff.

<sup>427</sup> Marshall, *Principles of Economics* (1890, 1961 ed.), p. 318; Knight, *The Ethics of Competition* (1935).

175. The basic argument concerning internal economies is that firms have to be above a certain size in order to be efficient. These economies have been attributed to the indivisibility of certain productive resources and processes, the fuller use of factors of production in larger firms, the specialization and division of labour which is contingent on a certain level of output, the possibilities of research and development and so forth. More specifically, the factors involved are the use of large and specialized machinery; the economy of raw materials and by-products; the specialization of labour and management; economy in purchase, sale, freight costs, and finances. Among these the optimum use of every machine; the better division of labour and the economy of skills and research and development of new products and production processes are probably the most important.<sup>428</sup> The argument in favour of large size is that all technical advantages available to the small firms are available to larger firms and, in addition, there are some which cannot be attained by small firms.

176. The concept of external economies is much more complicated and more elusive than that of internal economies. In a broad sense, external economies have been defined as those economies which take place when, as an industry expands, costs for all firms within the industry are reduced independent of their own individual outputs.<sup>429</sup> No simple classification of external economies, as the concept has evolved, seems possible, but among the most important effects of scale are those emanating from the indivisibilities in the supply of overhead capital and from the interdependence between production units and firms. As far as the former are concerned, a number of writers have stressed the capital lumpiness of public utilities such as roads, railways, harbours, electric power installations and so forth.<sup>430</sup> An increase in scale will make it economically feasible to create such facilities, the existence of which evidently benefits firms and industries in a number of ways, or leads to their fuller utilization, with a consequent reduction in the costs of these services rendered to industry. Several authors have even

argued that large countries have similar advantages with respect to public administration, defence and so forth.<sup>431</sup> The other type of external economies reflects the interdependence or complementarities between individual plants and firms, as well as those existing in the economy as a whole.<sup>432</sup> The complementarities between individual firms, for example, could take the form of services provided free, without compensation, by one producer to another or of a reduction in the cost of the average firm. A distinction is sometimes made in this connexion between horizontal external economies which reflect the interdependence of production functions at the same stage of development (such as, for instance, the economies which the development of one consumer good through increased purchasing power and consumer spending transmits to another) and vertical external economies which accrue to a firm or industry because of the expansion of other industries higher up or lower down in the production structure.<sup>433</sup> Another distinction is that between technical external economies among industries technically dependent upon each other (of which an example is the benefits of labour markets for special skills created by other firms), and pecuniary external economies which are transmitted through the price systems (such as, for instance, when lower prices in one industry are passed on to industries which use products of the first as inputs).<sup>434</sup>

177. The external economies depending on the interdependence of all firms and industries have acquired special significance because of the implications they are supposed to have for the development of the economically less advanced countries. The view that there is a need for different segments of the economy to remain in step was first proposed by Rosenstein-Rodan. He argued that economic development required an increase of the market size not only to obtain the external economies of large-scale production, but also and, especially, those which arise from simultaneously developing a large number of industries. He argued that the complementarity of different industries provides the most important of arguments in favour of a large-scale planned industrialization.<sup>435</sup> This complementarity, manifesting itself through de-

<sup>428</sup> Marshall, *Principles of Economics* (1890, 1961 ed.), pp. 278-285; Stigler, *Production and Distribution Theories* (1941), pp. 77-83; Lewis, *The Theory of Economic Growth* (1963), pp. 76-78; Mehta, *Measurement of Industrial Productivity* (1955), p. 40; Belshaw, *Population Growth and Levels of Consumption* (1956), pp. 67-68; Leibenstein, *Economic Backwardness . . .* (1957), p. 106; Vakil and Brahmananda, "The problems of developing countries" (1960); Marcy, "How far can foreign trade and customs agreements . . ." (1960).

<sup>429</sup> Marshall, *Principles of Economics* (1890, 1961 ed.), pp. 284, 317, 615, 808, introduced the concept of external economies. He held that these were continually growing in importance relative to internal economies. He distinguished economies in the use of skills and machinery due to volume of production in general through increased knowledge and technical progress and its concentration in certain localities; economies of division of labour due to geographical concentration and the economies due to the development of mutually dependent branches.

<sup>430</sup> Lewis, *The Theory of Economic Growth* (1963), pp. 72-73, 264-265, 324; Belshaw, *Population Growth and Levels of Consumption . . .* (1956), pp. 68-69; Robinson, "Population and development" (1960); Stigler, "Economic problems in measuring . . ." (1961); Rosenstein-Rodan, "Notes on the theory . . ." (1961). Myint, *The Economics of the Developing Countries* (1965), pp. 115-117, also argued, however, that large social overhead capital can be timed and phased, giving considerable flexibility.

(Continued on next page)

mand,<sup>436</sup> will reduce the risk of not finding markets, increase the incentives to invest and thus make it possible to overcome the indivisibilities in the production functions. This approach, implying a shift of emphasis from the effects economies of scale have in reducing cost to those of stimulating investment, has led to the notion and advocacy of the "big push" and "balanced growth". If there were no indivisibilities, balanced growth could be achieved with any level of investment, but since indivisibilities are considerable, balanced growth requires large investments or a "big push".<sup>437</sup> The theory of balanced growth has been criticized in particular by Hirschman, who argued that it failed as a theory of development in so far as it implies that a whole new, self-contained, modern industrial economy would be superimposed on the stagnant, subsistence economy. Instead, he argued that the process of economic development should be seen as a series of disequilibria which create a pattern of inducements and pressures making for further growth.<sup>438</sup>

178. The existence and importance of economies of scale have been questioned by a number of writers. Arguments in this connexion concern mainly the size of the firm. The available evidence, it is asserted, suggests that the average size of the plant in different countries tends to be very much alike and that no long-term trend towards an increase—or decrease—of this average appears to exist, it being implied that if such economies existed the size would be larger or increasing.<sup>439</sup> Another argument is that, apart from some exceptional industries, technical economies are exhausted by firms of rather moderate size and even that these may in fact have the best efficiency. Several reasons have been brought forward why this might be so: small firms have greater

(Footnote 435 continued)

spend all their wages on shoes, implying thus a shortage of demand for shoes if nothing else changed in the economy. However, if instead a large number of unemployed or underemployed were put to work in a whole range of industries, since the new producers are each other's customers, this would create sufficient demand for all goods. See also Nurkse, *Problems of Capital Formation* . . . (1953), pp. 14-15; and his "Some international aspects of the problem . . ." (1952).

<sup>436</sup> The idea that there should be a balance in supply in the sense that the different sectors of the economy have to grow together without any one getting too far out of line has also been proposed by several other writers. Scitovsky, "Two concepts of external economies" (1954); Lewis, *The Theory of Economic Growth* (1963), pp. 274-283. For a critical discussion of balance in demand and in supply see Hirschman, *The Strategy of Economic Development* (1958), chaps. 3 and 4.

(1957), p. 107; Singer, "Balanced growth in economic development . . ." (1964); Myint, *The Economics of the Developing Countries* (1965), pp. 103, 110, 117-118; Hagen, *On the Theory of Social Change* . . . (1962), pp. 44-47.

<sup>438</sup> Hirschman, *The Strategy of Economic Development* (1958), chap. 4.

<sup>439</sup> Jewkes, "The size of the factory" (1952); and his "Are the economies of scale unlimited?" (1960). He noted that there was no clear evidence for a long-term trend towards an increase or decrease of the average size of the firm in different countries. However, the proportion of employees found in factories employing 2,000 or more increased in Great Britain from 18.4 per cent in 1950 to 20.6 per cent in 1955 and in the United States factories employing 2,500 or more employees increased their proportion from 17.7 per cent in 1947 to 20.0 per cent in 1952.

flexibility to adjust to changes in demand; diseconomies in large firms may arise from increased administration and management problems; some costs may be independent of the size of output; technological innovations may tend to benefit in particular the small firm.<sup>440</sup> Even many of those writers who think that, in general, economies of scale may be important agree that even relatively poor and small countries can usually have at least one firm of optimum scale in many industries.<sup>441</sup>

179. Those who contend that economies of scale exist point to the relation between the size of the firm, in terms of output, and its efficiency, as measured by output per worker. A number of investigations have suggested that such correlations exist especially when localized industries are excluded. The results of several of these studies indicate that the correlations between total output and output per worker is of the order of +0.5 to +0.7.<sup>442</sup> Another argument is that even if large-scale factories are not the rule, for certain products the minimum and optimum size of the plant or firm is very large. Industries usually included in this category are aircraft, automobile and truck, heavy railroad equipment, heavy machine tool and heavy electrical equipment manufacturing.<sup>443</sup> With regard to the economies external to the firm, a number of writers have asserted that even though the individual firm need not be large to be efficient, because of the extent to which industries depend upon each other as far as resources materials, components, services or intermediate outputs or by-products are concerned, the advantages of specialization cannot be fully secured in the absence of other industries or markets of a certain size. In a large economy, advantages of this type will become available to young or infant industries sooner than in a small economy.<sup>444</sup> Several additional advantages are thought to be associated with large-scale production. It has been argued that despite the relative ease with which the minimum size

<sup>440</sup> Jewkes, "Are the economies of scale unlimited?" (1960); Mehta, *Measurement of Industrial Productivity* (1955), pp. 45-46; Edwards, "Size of markets, scale of firms . . ." (1960). Some of these writers assert that smaller firms may even have certain advantages such as greater flexibility; lesser management problems etc. Blair, "Does large-scale enterprise result in lower cost? Technology and size" (1948), thought that for many kinds of enterprises, technological innovations had tended to shift towards a smaller size the point at which internal economies of scale cease and diminishing returns to scale set in. On this discussion, see also Stigler, "The division of labor is limited . . ." (1951); Belshaw, *Population Growth and Levels of Consumption* . . . (1956), p. 74.

<sup>441</sup> Rosenstein-Rodan, "Notes on the theory . . ." (1961); Leibenstein, *Economic Backwardness* . . . (1957), p. 106; Robinson, "Introduction" (1960).

<sup>442</sup> Rostas, *Comparative Productivity in British* . . . (1948); Frankel, *British and American Manufacturing Productivity* . . . (1957). See also Stigler, "Economic problems in measuring . . ." (1961). For a study comparing different countries, see Kuznets, "Quantitative aspects of the economic growth of nations, I . . ." (1956). Fabricant, "Study of the size and efficiency of the American economy" (1960), concludes tentatively that although the results obtained may exaggerate the correlation between size of industry and its efficiency, some correlation between the two is likely.

<sup>443</sup> Robinson, "Introduction" (1960); Jewkes, "Are the economies of scale unlimited?" (1960); Kuznets, "Economic growth of small nations" (1960).

<sup>444</sup> Lewis, *The Theory of Economic Growth* (1963), pp. 77, 324; Robinson, "Introduction" (1960); Fabricant, "Study of the size and efficiency of the American economy" (1960).

of the firm can be attained even in smaller countries, in such countries a decrease of competition and the creation of monopolies may develop more easily, and may have various drawbacks including the possibility of lessened efficiency.<sup>445</sup> Another advantage of a large-scale economy, it has been asserted, is that in such an economy the risks associated with the establishment of a new firm are much less, since even a slow rate of growth of the economy might justify such an addition.<sup>446</sup>

180. There exists considerable controversy as to the possible effects of population size on the economies of scale which can be attained. In the chain of reasoning according to which the larger the size of the firm the lower the cost per unit of product; the larger the market the larger the size of the firm; and the larger the size of the country the larger the market; the most difficult link to establish is that between the size of the market and the size of the country.<sup>447</sup> Clark thought that probably the majority of industries, working under increasing returns, are benefited by a larger population.<sup>448</sup> Various other writers concluded that there are economies of scale in a larger population, although qualifying their views.<sup>449</sup> Different views are based on the argument that the realization of economies of scale depends essentially on the size of the market as such, rather than on the size of population.<sup>450</sup>

181. One problem of interpreting findings as to the relation between economies of scale and the size of population is that of the lack of a clear dividing line between large and small nations. Kuznets considered as small nations those with a population of ten million or less.<sup>451</sup> Robinson suggested a dividing line of between 10 and 15 million inhabitants, but noted that differences in the degree of diversification appeared to occur on a continuous basis.<sup>452</sup> Jewkes estimated that a population of 20 million would be large enough to permit the realization of the

full economies of large-scale production.<sup>453</sup> Whelpton asserted that a population of 100 to 135 million would be sufficient to maximize output per head in the United States.<sup>454</sup> An analysis based on data for a large number of countries led Chenery to conclude that an increase in the population from 2 to 50 million causes manufacturing output *per capita* to nearly double and that in the sectors where economies of scale may exist the figure would triple. Although he inferred that beyond some point market size would have a lesser effect in countries with an income of some 300 dollars or more, economies of scale in these industries would be probably significant up to a population of 100 million or more.<sup>455</sup> Pearson concluded that while economies derived from economic integration of countries with 10 to 15 million inhabitants might be substantial, the economies of scale by integrating countries with populations of the order of 50 million might be questionable.<sup>456</sup>

182. The problem of the size of population and economies of scale in developing countries is more complicated. In many developing countries a diversified expansion of productive facilities is made difficult or impossible because of the high investment requirements and low savings capacity, as well as by reason of an insufficient demand to justify optimum capacity.<sup>457</sup> Deficiencies in social overhead capital caused by diseconomies on capital account in developing countries may more than outweigh any economies of scale.<sup>458</sup> In addition, account must be taken of the fact that in the economically less developed countries the majority of the population still depends on agriculture, which is much more likely to be subject to diminishing returns than to increasing returns. Density rather than size of population might be the crucial factor under these circumstances. In addition, it has been argued that small countries not having the benefit of economies of scale may overcome such a situation through external trade.

#### (b) *Population size, specialization and economies of scale*

183. The degree of specialization of an economy, in the sense of the range of goods and services it produces, is held to depend to a great extent on the size of its population. Nations with a smaller number of inhabitants, it is

<sup>445</sup> Lewis, *The Theory of Economic Growth* (1963), p. 96; Robinson, "Introduction" (1960); Edwards, "Size of markets, scale of firms..." (1960).

<sup>446</sup> Robinson, "Introduction" (1960); Jewkes, "Are the economies of scale unlimited?" (1960).

<sup>447</sup> Vakil and Brahmananda, "The problems of developing countries" (1960).

<sup>448</sup> Clark, "Population growth and living standards" (1953). On this point, see also Belshaw, *Population Growth and Levels of Consumption*... (1956), pp. 72-73.

<sup>449</sup> Kuznets, "Economic growth of small nations" (1960); Marcy, "How far can foreign trade and customs agreements...?" (1960). Lewis, *The Theory of Economic Growth* (1963), p. 72, noted that the size of the market depends upon population size, but that several other factors are involved. Fabricant, "Study of the size and efficiency of the American economy" (1960), pointed out that the lack of conclusive knowledge as to whether technical advances are of the kind favouring large-scale production limits the possibility to say whether size increases efficiency.

<sup>450</sup> Vakil and Brahmananda, "The problems of developing countries" (1960); Robinson, "Population and development" (1960).

<sup>451</sup> Kuznets, "Economic growth of small nations" (1960); but he added that this classification is based on the distribution of nations by size, as at present. For earlier times, the limit should be progressively lowered.

<sup>452</sup> Robinson, "Introduction" (1960). He noted that differences in the degree of diversification between countries of 10 to 15 million and of 50 million may be as important as differences between the latter and countries with a population of about 200 million.

<sup>453</sup> Jewkes, "The population scare" (1939). See also Spengler, "Demographic patterns" (1954), who asserted that the United States and the larger European countries had passed the optimum. See his "Population and *per capita* income" (1945).

<sup>454</sup> Whelpton, *Forecasts of the Population of the United States, 1945-1975* (1947), pp. 64-66. See also Spengler, "Demographic patterns" (1954).

<sup>455</sup> Chenery, "Patterns of industrial growth" (1960). See also Chenery and Taylor, "Development patterns: among countries and over time" (1968).

<sup>456</sup> Pearson, "Income distribution and the size of nations" (1965).

<sup>457</sup> Scitovsky, "Croissance balancée ou non-balancée" (1959); Leibenstein, *Economic Backwardness*... (1957), pp. 106-107. Vakil and Brahmananda, "The problems of developing countries" (1960), asserted that only in the context of a proportionate availability of other factors, population size might be an important factor.

<sup>458</sup> Rosenstein-Rodan, "Notes on the theory..." (1961). Myint, *The Economics of the Developing Countries* (1965), pp. 116-117, commented, however, that various developing countries already possess considerable social overhead capital.

asserted, are as a rule characterized by a less diversified economy and a greater concentration on a limited range of products or, conversely, the bigger the population, the greater the opportunities for the efficient production of all kinds of goods and services. This tendency towards a higher degree of diversification as population size increases reflects primarily the existence of economies of scale but may be re-enforced in so far as the size of the population is positively associated with the size of the territory. Since the variety of mineral and other natural resources found in a country depends largely on the size of its territory, a smaller population and territory would tend to be more specialized because its natural resources would be less diverse. In addition, having relatively more resources per head of a certain type might give rise to economies of scale in their exploitation or their use in manufacturing, thus making for a higher degree of specialization.<sup>459</sup>

184. Closely related to the lesser degree of diversification of small countries is their dependence on foreign trade. This greater importance of trade in the economy of the smaller countries may be basically explained by the same factors which determine their higher degree of specialization.<sup>460</sup> In more general terms, it may be argued that, given the greater concentration on a limited range of products, foreign trade must be more important for smaller nations than for larger ones. A number of findings have confirmed that the smaller the population, the higher the ratio of imports and exports to national product or income, and that the extent to which countries depend on international trade is to a considerable degree predictable on the basis of the size of their populations. Kuznets found on the basis of data for fifty-three countries in the years 1938-1939 a rank correlation coefficient of  $-0.44$  between population size on the one hand, and the export ratio or the relation between exports and national income on the other hand; the corresponding coefficient for the import ratio was  $-0.56$ .<sup>461</sup> In a later study, based on data for sixty-two countries, he confirmed these results, finding a systematic association between the trade proportion—being the sum of imports and exports divided by gross national product—and the size of the population.<sup>462</sup> Using data for 1955 from seventy-three countries, it was found in another study that population size accounted for more than 60 per cent of the variation

in the ratio of foreign trade to gross national product.<sup>463</sup> An analysis of imports and exports of a number of important products of manufacturing industries in thirty-two countries confirmed the hypothesis that smaller countries appear to experience a comparative disadvantage in most of the main manufacturing industries.<sup>464</sup>

185. The importance of population size for determining the foreign trade ratio has been confirmed both for the economically more developed and the economically less developed countries. Ranking thirty higher income countries according to size in classes of five countries each, Kuznets found that the ratio of foreign trade *per capita* to income *per capita* for the year 1949 increased from somewhat less than 22 per cent in the five largest countries to nearly 84 per cent in the five smallest. Comparable data for thirty lower income countries revealed an increase from less than 38 per cent to over 64 per cent. Noting the more pronounced increase of the ratio in the group of more developed countries, Kuznets attributed it to the higher variety of demand at more advanced stages of the development and the consequent reliance of these countries on ties with the larger economies.<sup>465</sup> Similar conclusions were reached by Adams, who found that the foreign trade ratio of large countries is likely to decline with higher levels of development, but that this is not so in the case of smaller countries. In the latter, in view of the proportionate increase in the demand for capital goods, an increase would be more probable. On the basis of cross-section analysis, he concluded that in the less developed countries the share of capital goods in imports decrease with a decrease in population, this share being 31 per cent in countries of 25 million inhabitants and 25 per cent in countries with less than 10 million inhabitants. In the developed countries, however, the reverse was true. In countries of 40 million or more inhabitants the share of capital goods in imports was 15 per cent, as compared with 31 per cent in countries with a population of less than 20 million, a difference which he attributed to the economies of scale.<sup>466</sup>

186. The common basis for trade is that countries can exchange their own products for goods which they would find it comparatively disadvantageous to produce. Through the specialization implied in it, trade offers countries which are smaller in population the possibility

<sup>459</sup> Kuznets, "Economic growth of small nations" (1960); and his "Quantitative aspects of the economic growth of nations, IX..." (1964). Keesing, "Population and industrial development..." (1968), finding a negative correlation between population size and density, as an index of *per capita* national resources, suggested that smaller countries had a comparative advantage in natural resources and a comparative disadvantage in manufactures, as the reverse of the former.

<sup>460</sup> Kindleberger, *Foreign Trade and the National Economy* (1962), pp. 32-36. Kuznets added to the earlier mentioned factors the circumstance that in smaller countries with a smaller area, transportation costs from boundaries may be lower than in larger countries. See his "Economic growth of small nations" (1960); and his "Quantitative aspects of the economic growth of nations, IX..." (1964).

<sup>461</sup> Kuznets, "Economic growth of small nations" (1960). He also noted that the correlations between *per capita* income and import and export ratios were low.

<sup>462</sup> Kuznets, "Quantitative aspects of the economic growth of nations, IX..." (1964).

<sup>463</sup> Deutsch, Bliss and Eckstein, "Population, sovereignty and the share of foreign trade" (1962), also concluded that foreign trade ratio tends to decline only moderately—from about 50 to 35 per cent—when population increased from 1 to 10 million, but accelerated when population further increased. With a population of 150 million it would drop to about 10 per cent.

<sup>464</sup> Keesing, "Population and industrial development..." (1968).

<sup>465</sup> Kuznets, "Economic growth of small nations" (1960). The increase in the percentages was, however, not continuous. In the case of the more developed countries there was one exception, and among the less developed countries the highest percentage was found in the group of countries which ranked fourth. See also his "Quantitative aspects of the economic growth of nations, I..." (1956).

<sup>466</sup> Adams, "Import structure and economic growth..." (1967). The findings discussed here were based on cross-section analysis; in the case of time-series the evidence, however, was less conclusive.

of obtaining most of the benefits of a wide market.<sup>467</sup> Nevertheless, there are certain advantages associated with having a larger population. In so far as it implies a larger area, having a larger population permits a greater diversification because of a broader range of natural resources.<sup>468</sup> Likewise, for both technological and social reasons, the international division of labour through trade falls far short of the optimum. Construction and housing, bulky products, internal transport and many personal services cannot be supplied by foreign trade. In addition, mainly for political reasons, a number of activities, for instance those related to defence, must be kept within the country, thus limiting the dependence on international trade.<sup>469</sup> Finally, larger nations, being more dominant in international markets and being less dependent upon them, are much less subject to the vagaries of foreign trade. In this connexion, it has often been argued that the more specialized a country the greater is the risk of instability. The smaller countries, for which trade is more important, are more vulnerable to fluctuations in international trade because a small percentage change in over-all trade represents a large amount in absolute value for a small country, including a large balance of payment deficit.<sup>470</sup> Nevertheless, some findings suggest that countries most active in trading are more stable than larger nations and that smaller countries adjust more easily to unfavourable changes in the world market, but apart from population many other factors are involved and the effect of population size is difficult to determine.<sup>471</sup>

187. An association between the size of a nation, on the one hand, and the diversification of the economy and economies of scale, on the other, may also have implications for the need for, and the possibility of obtaining foreign capital funds. If it can be assumed that, because of their size, smaller nations have more limited capital markets than larger ones, in order to diversify their economy over a wide range of products, they have to rely also to a larger extent on foreign capital for financing such activities.<sup>472</sup> However, the foreign investments which flow into a country, it has been argued, depend not only on how productive they are by themselves but also upon the efficiency of all other industries in the economy.<sup>473</sup> Since the latter is determined at least in part by economies or diseconomies of scale, smaller countries might not only be more dependent on foreign investment, but in addition, because they are in a less favourable position as far as the existence of economies of scale is concerned, might

encounter more difficulties than larger nations in securing the foreign capital they need.

### (c) *Population density and diminishing returns*

188. The interactions between population size and natural resources may affect productivity in a number of ways. As has been noted above, if it can be accepted that a positive relation exists between the size of the population and the size of the territory, a more numerous population may have the benefit of a larger and more diversified resource base which permits a higher degree of diversification of the economy. More important, however, are the implications for productivity of the ratio of population to natural, and, particularly, to agricultural resources or the density of population, to the extent that the latter is representative of the ratio of population to resources.<sup>474</sup>

189. The argument linking population density to productivity is based on the theory of diminishing returns in agriculture, which was the corner-stone of Malthusian and classical economic theory. Decreasing returns in agriculture are attributed to two factors which, it was thought, characterized production based on natural resources. First, the supply of such resources is fixed both in quantity and quality; second, it is asserted, the possibilities of a far-reaching division of labour and of technological progress in agriculture were limited. The reasoning was then that, because of these constraints, once a certain level of density and utilization of the cultivable land had been reached, further increases in production could occur only through the cultivation of land of inferior quality or through the application of more labour to land already under intensive cultivation.<sup>475</sup> Although at low levels of density agricultural production might be subject to increasing returns, once a certain level of density had been reached decreasing returns would set in. The high agricultural population density in many of the developing countries is, therefore, thought to be one of the main causes of the low productivity found in agriculture.

190. The implications of the man-land ratio for productivity are intimately related to employment aspects and have been discussed especially in connexion with the widespread underemployment found in the peasant, subsistence agriculture in the developing countries with a rural "over-population".<sup>476</sup> This chronic underemployment is usually identified with very low levels of productivity. In fact, according to many writers, in the overpopulated peasant economies the productivity of labour is negligible, zero or even negative over a wide range, so that, even with unchanged techniques, a part of the labour force could be removed from agriculture without significantly reducing agricultural production. In more specific terms, productivity will be low under these conditions because of the average worker having

<sup>473</sup> Lewis, *The Theory of Economic Growth* (1963), p. 249.

<sup>474</sup> The limitations of either over-all, agricultural or rural density as an indicator of the relation between population and resources and the difficulties of designing a more appropriate indicator have been mentioned in section C. It is here assumed, as is often the case in demographic literature, that in principle some measure of density exists which would fulfil these conditions.

<sup>475</sup> See chapter III, sections C and D.

<sup>476</sup> See section C above.

insufficient land at his disposal, and extreme reduction in the size of holdings is inevitable, thus reducing the worker's production to only a fraction of his productive capacity.<sup>477</sup>

191. Even though the concept of disguised unemployment, in a strict sense, abstracts from technological change,<sup>478</sup> the pressure of population on agricultural resources is unlikely to leave techniques and methods of production unchanged; and various arguments have been advanced as to why it might contribute to holding back technological progress. In the first place, low incomes at or near the subsistence level will considerably reduce willingness to take the risks frequently involved in the application of new techniques and thus deter technological innovation.<sup>479</sup> The ability to introduce new techniques is further restricted by the circumstance that while, on the one hand, low incomes make the capital that is available for investment very scarce, on the other hand, technological progress requires nearly universally substantial increases in capital.<sup>480</sup> This is the more so since in densely settled agricultural areas land is used very intensively and requires proportionately higher capital outlays for such improvements as irrigation, land reclamation and so forth.<sup>481</sup> In addition, the small holdings typical of these economies offer little scope for mechanization and capital intensification or make them less productive.<sup>482</sup> Whereas the relative scarcity of land and capital in the overpopulated peasant economies severely limits technological progress, the other factor of production—labour—is free within the family and will thus be used until its marginal product is zero. On this ground there are no incentives to introduce labour-saving techniques which would only reinforce the existing underemployment.<sup>483</sup> Because of these factors, it is often held that substantial technological progress and the introduction of new methods of production are not possible without a reduction in the number of agricultural workers.<sup>484</sup>

<sup>477</sup> Several writers have asserted that the problem of unemployment is not so much that there is too much labour applied but that there is a surplus of labourers who work only for a limited time. (1953), pp. 34, 52-53; United Nations, *Processes and Problems of Industrialization* . . . (1955), pp. 3-4; Hoselitz, "Agriculture in industrial development" (1962). Sen, *The Strategy for Agricultural Development* . . . (1962), p. 29, noted that while mechanization of farms considerably improved the yield per unit of labour, it does not necessarily raise that per unit of land. Therefore, in countries with

192. Overpopulation under forms of production other than the peasant subsistence economy is likewise thought to have a negative effect on productivity. Where agriculture is mainly operated by paid labour, the abundant supply of labour tends to keep wages low in relation to other factors of production. The combination of surplus labour and low wages provides little or no incentive for the introduction of more efficient methods of cultivation and technological progress.<sup>485</sup> The same is likely to hold where tenant farmers are concerned. Because the scarcity of land makes for intense competition, average holdings will be small, creating conditions not unlike those in the peasant subsistence sector, and in addition rents will be high and the tenant's share low, all factors tending to reduce the incentive and possibilities of introducing more efficient methods of cultivation.<sup>486</sup>

193. Various aspects of the theory of productivity and underemployment in the overpopulated agricultural economy have been criticized. The assertion that labour could be removed from the land without a noticeable decline in production, or, in other words, the assumption that the marginal productivity of labour would be zero, have been questioned by several writers, as indicated in section C above. The argument that high population density would virtually exclude the possibilities of technological progress has been discounted by others. In general, it has been suggested that methods of production are flexible enough to make it possible to increase production when labour is added while other factors of production remain constant,<sup>487</sup> and that techniques of production adapt themselves to the relative plenty of labour and the relative scarcity of land and capital.<sup>488</sup> More specifically it has been argued that there are considerable opportunities in densely settled developing countries for raising agricultural output by such relatively cheap means as improved seeds, better rotation, better tools etc.<sup>489</sup> Socialist writers, in particular, have argued that underemployment and excess population in capitalist countries are the result of the introduction and spread of capitalist

a high man-land ratio in agriculture, the scope for mechanization would be very limited until the ratio could be reduced substantially by means of the transfer of labour out of agriculture.

<sup>485</sup> Taeuber, "Utilization of human resources in agriculture" (1950); Lewis, "Economic development with unlimited supplies of labour" (1954); Raj, *Employment Aspects of Planning* . . . (1957), p. 37; Myint, *The Economics of the Developing Countries* (1965), pp. 56-57.

<sup>486</sup> Clark, "Future sources of food supply . . ." (1962), drew attention to the fact that high population density and high rents may cause a regression in production methods and techniques.

<sup>487</sup> Viner, "Some reflections on the concept of disguised unemployment" (1957). Mellor, *The Economics of Agricultural Development* (1966), chap. 9, also thought that production could be increased through the increase of labour input, but noted that incentives might not be strong enough to induce the additional effort.

<sup>488</sup> Phelps Brown, *The Economics of Labor* (1962), p. 108.

<sup>489</sup> Singer, "The mechanics of economic development . . ." (1952). Belshaw, *Population Growth and Levels of Consumption* . . . (1956), pp. 75 and 105, noted, however, that once these improvements have taken place, further increases in labour would lead to diminishing returns.

methods of production and the mechanization of agriculture.<sup>490</sup>

194. The case of the sparsely populated agricultural countries poses problems different from those in the more densely populated areas. Where there are large resources of cultivable land which cannot be utilized because of factors related to the size of the population—such as the lack of labour supply, the distance to markets, or the inadequacy of transportation facilities—higher population density might increase productivity. Since land is relatively plentiful under these circumstances, conditions for progress in agricultural techniques are favourable and increases in output per worker, it has been argued, may be possible without heavy capital outlays. Improved knowledge of seed selection, crop rotation, soil conservation and the use of fertilizers and livestock feeding are among the factors which might increase productivity.<sup>491</sup> However, according to others, considerable investments in overhead capital such as transportation facilities and communications may be necessary to make effective the potential higher productivity in these areas.

195. A negative relation between rural or agricultural density and productivity in agriculture has been generally suggested. In the densely settled agricultural areas, the high levels of underemployment might by themselves be considered an indication of low efficiency in so far as this underemployment is assumed to have as one of its main characteristics a low productivity. Nevertheless, as has been noted before, the prevalence of large-scale underemployment in this sense has been questioned by a number of writers. The results of a number of studies have shown in general that the higher the density, the lower the production per agricultural worker.<sup>492</sup> Clark found production per farm worker to vary inversely with the square root of male workers per thousand hectares of farm land.<sup>493</sup> The evidence as to the relationship is, however, not conclusive; even where an inverse relation between density and productivity exists, it does not imply a causal relation, and factors other than density are operative. In more general terms, the degree of overpopulation is not only a function of the relation between size of population and the quantity of resources but also of the level of technology and especially of economic development.<sup>494</sup> Some findings seem to confirm this:

<sup>490</sup> Academy of Sciences of the USSR, Institute of Economics, *Political Economy* (1957). Falkowski, *Les problèmes de la croissance du tiers monde . . .* (1968), pp. 75-77, notes that in socialist literature the problem of property and its deformed structure are seen as the main causes of agricultural stagnation.

<sup>491</sup> Nurkse, *Problems of Capital Formation . . .* (1953), p. 52; Kuznets, "Economic growth of small nations" (1960). Myint, *The Economics of the Developing Countries* (1965), pp. 56-57, noted, however, that in the colonial period under the plantation system even in sparsely settled areas productivity remained at a low level owing to the policy of keeping wages low, which led to the extensive use of cheap labour at low levels of productivity.

<sup>492</sup> Black, "Agricultural wage relationships . . ." (1936); Johnson, "Contribution of price policy to the income . . ." (1944); and his *Forward Prices in Agriculture* (1947); Moore, *Economic Demography of Eastern and Southern Europe* (1945), pp. 35, 195 ff.; Daniel, "Regional differences of productivity . . ." (1944).

an analysis based on data for seventy countries showed that virtually no relation existed between national income per head and density of population.<sup>495</sup>

196. Despite the lack of conclusive evidence on the direct relation between population density and productivity, diminishing returns to scale are generally assumed to be characteristic of agriculture.<sup>496</sup> Since increasing returns are assumed to be typical of manufacturing, the relationship between population and output per head is a question of the advantages of specialization and the economies of large-scale production mainly found in manufacturing, on the one hand, and the diseconomies of more intensive and extensive use of natural resources, on the other.<sup>497</sup> Given the predominance of economies of scale in industry and diseconomies of scale in agriculture, it follows that the population which a country can support without diminishing returns is likely to set in much earlier in the predominantly agricultural developing countries, where the ratio of farming to secondary activities is high, than in the more developed, industrialized countries.<sup>498</sup>

## 2. THE AGE DISTRIBUTION AND PRODUCTIVITY

197. The age factor may be of importance from the point of view of productivity for two reasons. First, the productivity and flexibility of workers is thought not to be independent of their age, and a different age distribution of the labour force may thus affect its productive capacity. In the second place, age is a factor which determines different needs, which in turn may imply different capital requirements; hence the age distribution may influence the structure of investment, particularly the not-directly productive as against the directly productive investments, and thus their productivity.

### (a) Age distribution of the labour force and productivity

198. The age composition of the labour force may determine the specific productivity of labour in so far as age is associated with the productivity of the worker, as well as with his capacity and willingness to adapt to changing production techniques or employment opportunities. Just as the capacities of different workers may vary, there may also exist variations in the capacity of the same individual at different stages of his lifetime.<sup>499</sup> It is generally assumed that the productivity of the worker decreases after a certain age because physical and mental capacities, as well as skills and energy, tend to decline with age; in addition, the individual's entrepreneurship and willingness to take risks weakens as he becomes older. A number of writers are, therefore, of the opinion that

<sup>495</sup> Pearson, "Income distribution and the size of nations" (1965).

<sup>496</sup> The existence of diseconomies of scale in agriculture was already noted by Marshall, *Principles of Economics* (1890, 1961 ed.), p. 285. See also Lewis, *The Theory of Economic Growth* (1963), p. 72.

<sup>499</sup> Kendrick, *Productivity Trends in the United States* (1961), p. 33.

and equipment by the time they enter the labour force, as well as for their education and professional training. An increase in the number of adults or workers implies added investments to supply the additional workers with capital goods. The effects of these changes on the capital-output ratio depends on the manner in which the workers are absorbed into the production process.<sup>509</sup>

### 3. POPULATION GROWTH AND PRODUCTIVITY

202. The possible implications of population growth for productivity are of special significance. On the one hand, since productivity defined in a broad sense can be interpreted as a measure of economic progress and the level of development,<sup>510</sup> the effect population growth or decline can have on it is part of the central issue of whether demographic change stimulates or retards economic progress. On the other hand, knowledge of the over-all or net effect of population on economic growth is still far from complete. This is partly so because much of the literature on demographic aspects of economic growth, regarded as a function of a nation's resources and the efficiency with which they are combined,<sup>511</sup> has been concerned mainly with the relationships between population and resources. Much less attention has been paid to, and much less is known about, the more complex question of the implications of population change for the less tangible determinants of productivity and economic growth.

#### (a) *Population growth, the factor proportions problem, dualism and productivity*

203. The discussion of the interrelations between population and co-operant factors of production and their consequences for productivity and economic growth was for a long time dominated by the problem of limited natural resources and land.<sup>512</sup> The fundamental proposition, which is still nearly universally accepted as far as the developing countries are concerned, was that because land was limited, population growth would cause diminishing returns to set in. The reasoning, used especially with respect to the more densely populated agricultural countries, is that, the quantity and quality of land being more or less fixed, after a certain point further population growth will give rise to a shortage of cultivable land and, as the rates of capital accumulation and technological progress in agriculture become low, returns to labour will decrease, causing the marginal productivity to decline to a very low level or even to zero.<sup>513</sup>

<sup>509</sup> Sauvy, "Investissements démographiques..." (1959).

<sup>510</sup> As mentioned above, in so far as productivity reflects the efficiency with which resources are converted into goods and services, it can be seen as a measure of economic progress. In addition, in a more formal sense, labour productivity or product per worker is, of course, closely associated with *per capita* income or product per person, in view of the relation between the total and working population.

<sup>511</sup> See the introduction to this chapter.

<sup>512</sup> For a review of some of the literature on this subject, see chapter III, sections C and D.

<sup>513</sup> Mandelbaum, *The Industrialization of Backward Areas* (1945), pp. 1-2; Robinson, "Economic consequences of a decline in the population..." (1951); Belshaw, *Population Growth and Levels of Consumption*... (1956), pp. 71-72, 75; Raj, *Employment Aspects*

204. This does not mean, however, that diminishing returns would always be found in agriculture when population was increasing. A number of writers, for instance, have commented on the fact that in sparsely settled areas population growth may under certain circumstances be a factor in increasing productivity. In such areas where there are plentiful resources, a growing population could, as noted before, open possibilities for a more efficient exploitation of the land, the reduction of transportation costs, the establishment of local markets and so forth.<sup>514</sup> Even so, once these areas became populated their problems would be similar to those of the already densely settled areas. More important, however, the experience of the presently developed countries has shown that technological progress and the increased use of capital, among other factors, have meant increased productivity and sustained expansion in agriculture, even when the country's population increased at a fairly rapid rate. Nevertheless, as has been pointed out, where such increases in productivity have taken place, they have in no way been dependent upon an increase in the agricultural labour force; on the contrary, they were in fact accompanied as a rule by the transfer of population out of agriculture to other activities.<sup>515</sup> In many densely settled agricultural areas of the developing countries, such a transfer is, in the view of many authors, essential for increasing productivity<sup>516</sup> and rapid population growth would make this process of structural change even more difficult, not in the least because of the additional capital which it requires.

205. Because of the preoccupation with economic development, and in view of the large investment needs of the development process, literature in more recent times has given increasing attention to the investment aspect and as far as the implications of population growth for economic development are concerned, to the interaction between population change and capital formation. In general terms, it may be said that if the existing stock of capital is fully utilized and technology remains unchanged, population and labour force increase are associated with a decline in the capital-labour ratio and output per worker unless capital expands at least as fast

(1955), pp. 3-4; Hoselitz, "Agriculture in industrial development" (1962); Sen, *The Strategy for Agricultural Development*... (1962), p. 29.

as the working population. Alternatively stated, as discussed in section B, for output to increase at the same rate as the total and working population, assuming that the latter two grow at the same rate, and thus for *per capita* income and product per worker to remain constant, the stock of capital should grow also at the same rate. Population growth, while tending to depress the rate of capital formation,<sup>517</sup> on the one hand, will involve, on the other, a cost in the form of demographic investments which reduces the potential higher productivity that would have been possible if population growth were absent or smaller.<sup>518</sup>

206. Taking into account the fixed quantity of land and the capital factor, the implications of the relation between population growth and physical resources for economic growth has been described in the following terms. An increase in population, other conditions being given, means an increase in the labour force which, assuming that the latter grows at the same rate as the total population, will be able to produce as much or more per worker, hence per head, if it is equipped with the same or a greater amount of capital per worker and if, making allowance for the increased pressure of population upon limited irreproducible resources, the reproducible capital-labour ratio remains the same.<sup>519</sup> If these conditions are not fulfilled, output per worker and per head would tend to decline.

207. The lack of proportion between labour and other factors of production is frequently considered to be one of the fundamental reasons for the low levels of income and productivity in many developing countries. Rapid population growth, by increasing this imbalance, is thought to create an additional obstacle to economic development.<sup>520</sup> Even though in the developing countries low productivity and chronic unemployment and underemployment are associated with the existence of a labour surplus compared to other factors of production, it has been argued that economic growth would still be possible if alternative techniques of production would make possible the substitution of labour for other factors, or if a market mechanism would exist by which factor prices and their supply and demand would be balanced. It has been asserted that structural disequilibrium at the factor level arises because of the imperfections in the price and market mechanism and because of limitations in

existing technology. This broader problem of the relationships among factors of production, the range of available techniques and the efficiency of the market mechanism has been analysed by Eckaus, who referred to it as the "factor proportions" problem,<sup>521</sup> and it is in turn closely connected with the problem of "dualism" thought to be characteristic of the majority of the developing countries.

208. The role of the market mechanism in ensuring that the prices of the factors of production adapt themselves to the equilibrium level where demand absorbs the existing supply was stressed in traditional theory. According to this theory, in the case of labour, wages would tend towards the equilibrium subsistence level. Since as long as wages remained above such a level population would increase and cause an excess supply of labour, it would reduce wages to the subsistence level; whereas when wages were below that level population would decline and the consequent scarcity of labour would raise wages and restore them to the equilibrium level.<sup>522</sup> Both the population theory as well as the assumed effectiveness of the market mechanism in bringing the supply of labour in line with the demand for it are no longer generally accepted. As far as the operation of the market is concerned, either because the price of labour is already at or near the subsistence level, or because for social, institutional or other reasons wages do not adapt themselves to a level where they would reflect the marginal productivity of labour,<sup>523</sup> the market mechanism is not considered efficient in bringing about the assumed equilibrium. More important is the fact that since modern thinking has discarded the hypothesis that population growth is a function of the level of wages or the wage bill<sup>524</sup> and in so far as mere population growth does not lead to further capital accumulation or new resource discoveries, a growing population will signify the appearance or increase of surplus labour accompanied by growing unemployment and falling *per capita* income, unless alternative production techniques, permitting factor combinations which reflect and adapt themselves to actual factor endowments and their changes, are available.<sup>525</sup>

209. As far as such technological choices are concerned, Eckaus asserted that only a limited number of production processes exist in large sectors of the economy and that these processes are, on the whole, relatively capital-intensive. Distinguishing two factors of production—labour and capital—he showed that where only one

<sup>525</sup> Singer, "Population and economic development" (1955).

technological process exists the two factors can be combined in only one way and, therefore, must be available in the required proportion if both are to be fully employed. The existence of more than one process, each with different factor combinations, increases considerably the total number of combinations, since the different production processes can be combined in a number of ways. Nevertheless, the number of alternative techniques is limited and if the proportions in which the factors are available falls outside the boundaries set by the available technological processes, unemployment of either labour or capital would ensue. Arguing that the use of advanced techniques in developing countries is not necessarily an irrational imitation of the more developed countries, Eckaus holds that technology and factor endowments characteristic of many developing countries are such that situations in which labour is redundant are often found.<sup>526</sup>

210. Closely associated with the existence of surplus labour and a shortage of co-operant factors of production in the less developed countries is the problem of "dualism". Among the first to introduce the concept of "dualism" was Boeke who, noting that a society is not necessarily dominated by a single social system, defined "dual" societies as those in which two or more social styles coexist, whereas in the normal historical evolution they would be separated from each other by transitional forms. Social dualism, which is the clashing of an imported system, which is capitalistic, with an indigenous system of another social style—predominantly non-capitalistic or pre-capitalistic—implied, according to Boeke, the need for a new dualistic heterogeneous theory which would combine those theories of each of these systems with that of the interaction between them.<sup>527</sup>

211. The existence of dualism in developing countries has become widely accepted. According to literature, a "dual" economy is characterized by two more or less clearly defined sectors: one, variously referred to as pre-capitalistic, backward, traditional or subsistent, consists mainly of agriculture, but may also include handicrafts, small industries and other associated activities where levels of productivity and income are usually low and stagnant; and the other is a capitalistic, advanced, modern or industrial sector in which techniques are advanced and levels of income and productivity are comparatively high.<sup>528</sup> The chief factor in this "dualism", it has been

noted, is the interrelationship between factor endowments and techniques of production.<sup>529</sup> The dual economy with its two distinct sectors emerges as a result of the introduction of modern techniques which require factor combinations not adapted to the resources available in these countries where capital and, in densely populated areas, land is scarce relative to population. The modern sector, using advanced technology, absorbs the existing capital, but since it employs only part of the labour force, the surplus manpower has to seek employment in agriculture and other low-productivity subsistence sectors.

212. One of the first writers to formulate a theory of the dual economy and its development was Lewis.<sup>530</sup> He assumed, in the classical tradition, the existence of an unlimited supply of labour in the sense that with the price of labour being at the subsistence level, the supply of labour exceeded the demand. With the supply of labour being unlimited and that of capital scarce, the latter would not be spread evenly over all labour but, applied in such a manner that the marginal productivity of labour equalled its current wage, employment would be determined accordingly. The capitalist sector, defined as the one which used capital, would thus only absorb part of the available supply of labour and the remainder would have to be absorbed in the subsistence sector, and earn what it could. Such an economy will expand, according to Lewis, if the profits of the capitalist sector are invested, and if wages in this sector are, as usually is the case, higher than in the subsistence sector.<sup>531</sup> Under these circumstances employment opportunities in the industrial sector expand and this increased demand for labour will be satisfied by workers from the subsistence sector attracted by the higher wages in the capitalist sector. As long as the supply of labour remains unlimited, the capital-

<sup>526</sup> Eckaus, "The factor-proportions problem in underdeveloped areas" (1955). See also Dorfman, "Mathematical or 'linear' programming . . ." (1953); Higgins, *Economic Development* . . . (1959), p. 340; Abraham-Frois, *Essai sur les problèmes d'investissement* . . . (1962), pp. 263-264; Bruton, *Principles of Development Economics* (1965), chap. 3.

<sup>527</sup> Boeke, *Economics and Economic Policy of Dual Societies* . . . (1953). For a critical analysis see Higgins, "The 'dualistic theory' of underdeveloped areas" (1956); and his *Economic Development* . . . (1959), pp. 275-293. On the need for a new theory of the development of the dual economy, see Jorgenson, "Testing alternative theories of the development of a dual economy" (1966); and Fei and Ranis, "Agrarianism, dualism and economic development" (1966).

<sup>528</sup> Boeke, *Economics and Economic Policy of Dual Societies* . . . (1953), pp. 12-20; Higgins, "The 'dualistic theory' of underdeveloped areas" (1956); and his *Economic Development* . . . (1959), p. 281; Jorgenson, "The development of a dual economy" (1961); and his "Surplus agricultural labour and the development of a dual economy"

(1967); Fei and Ranis, "A theory of economic development" (1961); and their *Development of the Labour Surplus Economy* . . . (1964), pp. 3, 7; Cairncross, *Factors in Economic Development* (1962), p. 21; Cotta, *Analyse quantitative de la croissance des pays sous-développés* (1967), p. 17. Fei and Ranis, "Agrarianism, dualism and economic development" (1966), made a distinction between agrarianism characterized by the overwhelming preponderance of agricultural pursuits, with other activities of relatively little importance; and dualism with as a central feature the coexistence of a large agricultural sector with an active and dynamic industrial sector.

<sup>529</sup> Higgins, "The 'dualistic' theory of underdeveloped areas" (1956); Das Gupta, "Underemployment and dualism—a note" (1964); Kindleberger, *Economic Development* (1965), p. 258; Jorgenson, "Surplus agricultural labour and the development of a dual economy" (1967).

<sup>530</sup> Lewis, "Economic development with unlimited supplies of labour" (1954). See also Higgins, *Economic Development* . . . (1959), pp. 353-357; Barber, "Disguised unemployment in underdeveloped economies" (1961); Enke, "Economic development with unlimited and limited supplies of labour" (1962); Jorgenson, "Surplus agricultural labour and the development of a dual economy" (1967).

<sup>531</sup> Lewis, "Economic development with unlimited supplies of labour" (1954), argued that in the capitalist sector wages would be higher due to conventional or institutional factors. On the existence of two distinct wage levels in the dual economy, see also Hirschman, "Investment policies and 'dualism' . . ." (1957); Higgins, *Economic Development* . . . (1959). Others have pointed out, however, that since labour is abundant wages in the capitalist sector would remain comparatively low: Boeke, *Economics and Economic Policy of Dual Societies* . . . (1953), pp. 142-144; Myint, *The Economics of the Developing Countries* (1965).

ist sector will continue to increase and the process will come to a halt only when capital accumulation has caught up with population and labour supply.

213. Eckaus, in his earlier mentioned study,<sup>532</sup> also analyses the case of under-developed and overpopulated economies in which two sectors can be distinguished: one where the relation between capital and labour is fixed, as might be typical for modern industrial activities, and one where a wide range of combinations of capital and labour are possible. On the basis of this model, he demonstrates that if the demand for output was such that a large part of the available capital is drawn into the fixed-coefficient, capital-intensive sector, which provides only limited employment opportunities, the remaining part of the abundant labour supply is pushed into the low productivity sector, with a high labour-capital ratio, but where at a certain stage unemployment is certain to appear.

214. The development of the dual economy with particular reference to the external sector was developed by Myint.<sup>533</sup> A country, according to Myint, starts a period of expansion when it is opened to economic relations with the outside world. At such a time the country may have a relatively sparse population in relation to natural resources. The development of the latter will be dominated by the production of primary goods for export and disequalizing factors start to operate between these advanced activities and groups and the traditional sector, thus giving rise to the emergence of economic and social dualism.

215. Most writers discussing "dualism" and the development of the "dual" economy have given only little attention to demographic considerations.<sup>534</sup> Lewis did not discuss in a systematic fashion the role of population growth in the development of the dual economy, but noted that population growth might be a source of additional labour supply which contributed to the unlimited supply of labour and that the growth of population would be relevant if it responded to economic development. He considered such a possibility likely, especially in the early stages of development, when mortality might decline without a simultaneous decrease of fertility. He also concluded that the surplus labour would eventually be

limited if the capitalist surplus would be growing more rapidly than population.<sup>535</sup> Eckaus showed that productivity might further decline and unemployment increase if the rate of population growth would exceed that of capital formation in the labour-intensive sector.<sup>536</sup> Myint noted that, whereas in the more developed countries, a time came when manpower became scarce, making it profitable for farmers to use more capital-intensive methods, in the less developed countries population growth brought about by the development of the modern sector meant that the supply of labour remained adequate, and instead of becoming scarce, labour later became in fact superabundant.<sup>537</sup> Other writers have also commented on the role of population in the development of an economy with unlimited supplies of labour. Minami noted that in those cases where labour force is growing rapidly and technological progress is limited, economic development is possible only if either the rate of growth of the labour force slows down or technological progress which is land-saving occurs.<sup>538</sup> Fei and Ranis underlined the fact that the faster the rate of population growth, the longer will be the take-off period and the more likely that the take off becomes impossible.<sup>539</sup> The importance of population in the development of the surplus-labour dual economy was, however, brought out, especially by Reynolds. Arguing that the kind of situation and models under consideration should be termed "high population growth" rather than "labour surplus" models, he stressed the fact that if the problem were merely one of absorbing a given initial labour surplus, the task might not be too difficult. The real difficulty, he asserted, is that that surplus is being continuously replenished by rapid population growth. Considering that most of the population increase accrues in the countryside, the important question in his view is whether labour-using inventions can be introduced rapidly enough in agriculture to hold back the decline in productivity and the increase in underemployment and its spread to the cities.<sup>540</sup>

<sup>532</sup> Eckaus, "The factor-proportions problem in underdeveloped areas" (1955). See also Higgins, *Economic Development* . . . (1959), pp. 325-330.

<sup>533</sup> Myint, "An interpretation of economic backwardness" (1954); and his *The Economics of the Developing Countries* (1965), chaps. 3-5. The case of an "open" dual economy has also been discussed by Barber, "Disguised underemployment in underdeveloped economies" (1961).

<sup>534</sup> Various other models of the development of the dual economy have been formulated, among them Jorgenson, "The development of a dual economy" (1961); and his "Surplus agricultural labour and the development of a dual economy" (1967); Fei and Ranis, "A theory of economic development" (1961); their *Development of the Labor Surplus Economy* . . . (1964); and their "Agrarianism, dualism and economic development" (1966); Sen, "Peasants and dualism, with or without surplus labor" (1966). For dualism viewed in regional terms see Hirschman, "Investment policies and 'dualism' . . ." (1957); and for the application of the development with unlimited supplies of labour to developed economies, see Kindleberger, *Europe's Postwar Growth* (1967).

<sup>535</sup> Lewis, "Economic development with unlimited supplies of labour" (1954). Higgins, *Economic Development* . . . (1959), p. 354, noted that even if economic development would not accelerate population growth, unlimited supplies of labour still would prevail if investment was not absolutely large relative to population growth, the industrial sector was small and population was growing rapidly. Jorgenson, "Surplus agricultural labour and the development of a dual economy" (1967), pointed out that Lewis's discussion on population was not integrated into his theory of economic development and that a sufficient condition for Lewis was the existence of an unlimited supply of labour.

<sup>536</sup> Eckaus, "The factor-proportions problem in underdeveloped areas" (1955).

<sup>537</sup> Myint, "An interpretation of economic backwardness" (1954).

<sup>538</sup> Minami, "Economic growth and labour supply" (1964).

<sup>539</sup> Fei and Ranis, "A theory of economic development" (1961).

<sup>540</sup> Reynolds, "Economic development with surplus labour . . ." (1969). Guha, "Accumulation, innovation and growth under conditions . . ." (1969), discussed the importance of population growth in holding down wages, as is assumed in the theory of development of the dual economy. The wage level, he asserted, can be held constant only if the absolute size of the agricultural population increases continuously. If not, capitalist expansion attracting workers from the land, would raise agricultural productivity, income and wages, raising also the wages in the capitalist sector and reducing profits, and thus the incentives for further accumulation.

216. The emergence and subsequent evolution of the "dual" economy with special reference to the population factor has been discussed by Higgins.<sup>541</sup> According to Higgins, at the beginning of the expansion process no factor of production is relatively abundant or scarce, but once the "population explosion" which accompanies the initiation of the industrialization process occurs, labour becomes redundant. This is so because the industrial investments which take place increase proportionately slower than population and, the technical coefficients in the modern sectors being relatively fixed, do not create sufficient employment opportunities for the entire population increase. Part of the larger population thus has to seek a livelihood in the traditional sector where, in the case of agriculture, the initial response to population growth is to bring additional land under cultivation. However, since both the amount of land and the capital which could be used in its exploitation are limited,<sup>542</sup> such possibilities are soon exhausted. Since the technical coefficients in the backward sectors are variable, as population increases further, the ratio of land and capital to labour will decline steadily; techniques will become increasingly labour-intensive and, as a result, marginal productivity will decline and disguised unemployment increase. Under these conditions, there will be no incentives for capital investments in the backward sectors, for labour-saving inventions or for higher effort on the part of labour. Thus, methods of production remain labour-intensive and the levels of techniques, productivity and income low.

217. In the case of the "dual" economy, the classical problem of the pressure of population on land, it has been noted, is considered in conjunction with the problem of the transfer of labour from the agricultural to the industrialized sectors of the economy. Development under these conditions requires a continuous shift towards industry and a rapid rate of labour absorption in these sectors.<sup>543</sup> Such a process requires, in the first place, large amounts of capital investments, but it raises, in addition, the question of the choice between alternative techniques of production and the possibilities of substitution between the factors of production and, especially, that of labour for capital.<sup>544</sup>

218. It is generally recognized that although in some cases factors of production are completely complementary, in the sense that they have to be used in fixed proportions, in most cases factor proportions can be varied. The extent to which factors of production can be and are substituted for each other depends both on technology and on the relative cost of the factors concerned.<sup>545</sup> As

noted before, it is often assumed that the possibilities of replacing capital by labour, especially in the modern sector, are limited,<sup>546</sup> but different opinions may be found on this question.

219. Findings as to the possibilities of substitution between factors of production are limited.<sup>547</sup> A number of authors have drawn attention to the considerable variations among countries in capital per person employed in a number of selected industries.<sup>548</sup> Bhatt, studying different input combinations on the basis of horsepower capacity, concluded that even in more developed countries technology is such as to permit the use of methods of varying capital intensity and that given the relative prices and the incentives for the use of less capital-intensive methods of production, less developed countries could adopt the least capital-intensive and the most labour-intensive method.<sup>549</sup> The analysis of data for a number of countries suggested that elasticity of substitution between capital and labour in manufacturing might typically be less than unity, while there was some indication that in primary production the situation might be the reverse.<sup>550</sup> In more general terms, it has been noted that findings suggest that in a certain number of activities it is technically feasible to substitute labour, as the abundant factor in developing countries, for capital, as the scarce factor.<sup>551</sup> It has also been observed, however, that even though capital-labour ratios can be varied considerably in such activities as transportation and construction without loss of efficiency and that in some industries it pays to use labour-intensive techniques, if labour is relatively abundant, such opportunities are limited. The technology which would permit a wide range of productive activities and would obtain high yields by using more labour in conjunction with capital does not exist.<sup>552</sup> It has, therefore, been argued that since goods and services are the joint product of labour and capital and since labour is not perfectly substitutable for other factors of production, output per worker tends to fall when, as a result of population and labour force growth, the amount of productive resources per worker declines.

<sup>546</sup> Notably Eckaus, "The factor-proportions problem in underdeveloped areas" (1955). Das Gupta, "Underemployment and dualism—a note" (1964), observed that in a technical sense the assumption of very limited factor proportions in industrial sectors is not necessarily true, but that institutional factors promoted the use of highly capital-intensive methods of production.

<sup>547</sup> A measure for such purposes is the elasticity of substitution which measures the speed with which the marginal productivity of one factor diminishes when it is substituted for another. See Allen *Mathematical Analysis for Economists* (1947), pp. 340-343; Arrow *et al.*, "Capital-labor substitution and economic efficiency" (1961); Babeau, "L'élasticité de substitution entre facteurs" (1964); and his "Elasticité de substitution. Répartition et croissance" (1964). See also on complementarity and substitution, Verdoorn, "Complementarity and long-range projections" (1956).

(b) *Population growth and the capital-output ratio*

220. Closely related to the aspects discussed in the preceding section is the effect of population growth on the capital-output ratio. In general terms, the use of the capital-output ratio in the Harrod-Domar type models<sup>553</sup> constitutes a deliberate theoretical simplification which does not, as a rule, correspond to reality. Its use not only implies the assumption of a fixed combination of capital and labour<sup>554</sup> but, in interpreting growth of income in terms of capital only, it does not explicitly take into account the role of other resources and factors in economic growth.<sup>555</sup> The over-all capital-output ratios are thought to be determined by a number of factors, the most important of which include: the nature of the production function for the whole economy, particularly with respect to returns to scale; the nature and direction of technological change; the relation of factor prices; the composition of demand and output.<sup>556</sup>

221. Various of the factors which determine the capital-output ratio are not independent of population growth and through them the latter may thus affect the capital-output ratio. Assuming, therefore, the capital-output ratio to be independent of the level of population growth implies an underestimation of the effects of population change.<sup>557</sup> In the present context, the implications of population growth for the structure of output and the patterns of investment, and for the factor proportions and the capital-output ratio are of special importance.<sup>558</sup>

222. Population growth is likely to affect the capital-output ratio through the patterns of investment in so far as a growing population needs certain overhead facilities. Such types of investment are not only lumpy but also have a high capital-output ratio. High population growth requires considerable investments in the expansion of educational facilities, as well as in the stock of capital

equipment in transportation, communications and so forth, or in general in not-directly productive investment, which will affect private investment, but may have repercussions especially for government spending.<sup>559</sup> One important category of investment that has received special attention in this connexion is the increased demand for housing, investment in which implies a high capital-output ratio, when population grows.<sup>560</sup>

223. While population growth tends, on the one hand, to increase the capital-output ratio through the structure of investment, it will tend to have the opposite effect, on the other hand, if it increases the relative scarcity of capital compared to labour. In general, it is assumed that the productivity of a given factor of production is greater the more abundant the supply of the other factor. Given the stock of capital and its increase, it is to be expected that the marginal capital-output ratio will be lower if the rate of population growth is higher since the same amount of capital would be associated with a larger labour force than if the population were growing more slowly. Conversely, it has been argued that a slowly growing population or a decline in the growth rate will imply a higher capital-output ratio.<sup>561</sup>

224. Various other arguments concerning the possible effect of population growth on the capital-output ratio are found in demographic literature. A rapid increase in population, it has been argued, permits capital accumulation without departing from the optimal ratio of labour to capital. In addition, a rapid population growth prevents the waste of capital by assuring markets for almost any investment.<sup>562</sup> In general, it appears that the assumption of a capital-output ratio independent of the growth of population and the labour force might exaggerate the disadvantages of a higher population growth as far as capital requirements are concerned. However, several writers have concluded that the tendency towards the increase of the capital-output ratio due to the increased demand for housing associated with population growth would outweigh the downward pressure on the capital-output ratio exerted by the other factors enumerated.<sup>563</sup>

<sup>553</sup> See section B of this chapter.

<sup>554</sup> The limitations of the Harrod-Domar model due to the assumption of fixed proportions were discussed especially by Solow, "A contribution to the theory of economic growth" (1956); and also Swan, "Economic growth and capital accumulation" (1956). See also Hahn and Mathews, "The theory of economic growth: a survey" (1964); Babeau, "Élasticité de substitution. Répartition et croissance" (1964).

<sup>556</sup> Bruton, "Growth models and underdeveloped countries" (1955); Kurihara, *National Income and Economic Growth* (1961), pp. 134-135; Lewis, *The Theory of Economic Growth* (1963), pp. 202-213; Myint, *The Economics of the Developing Countries* (1965), pp. 94-98. Leibenstein, *Economic Backwardness* ... (1957), pp. 177-178, stressed the importance of the use of agents other than capital in the production process. Hirschman, *The Strategy of Economic Development* (1958), pp. 30-32, emphasized the importance of the level of development, arguing that whereas the use of a Harrod-Domar type model might be appropriate in the more developed countries, it would not be so in the less developed countries. For a general discussion, see also Redl, "Versuch einer ökonomischen Theorie ..." (1964).

<sup>557</sup> Myint, *The Economics of Developing Countries* (1965), p. 94.

<sup>558</sup> The effects of population growth on economies of scale and on technological progress are discussed below, as are some aspects of the interrelations between population growth and human capital, as opposed to physical capital.

<sup>562</sup> Clark, *The Conditions of Economic Progress* (1957); Higgins, *Economic Development* ... (1959), p. 648; Abraham-Frois, *Essai sur les problèmes d'investissement* ... (1962), pp. 84-85.

<sup>563</sup> Lewis, *The Theory of Economic Growth* (1963), p. 205; Redl, "Versuch einer ökonomischen Theorie ..." (1964). This conclusion would, however, be completely valid only if the need for housing gave rise to an effective demand.

(c) *Population growth and economies of scale*

225. The assumption that a proportionate increase in capital or in both capital and labour results in the same proportionate increase of output implicitly attributes all extra output to the additional labour and investment. Among the many other factors which contribute to production are the returns to scale. Population growth is thought to affect the possibilities for economies of scale in a number of ways, but as in the case of the size of population, these effects are to a great extent contingent on prevailing conditions and difficult to assess in specific terms.

226. Population growth, according to Sauvy, may in several ways contribute to creating additional economies of scale. A growing population, he asserts, increases the possibilities of advanced specialization of enterprises because of larger markets, of the specialization and division of labour for the working population and of reducing in relative terms those general costs of a nation, such as public outlays, which are independent of the size of the nation or increase less rapidly than the number of people.<sup>564</sup> Spengler also stressed the opportunities for the division of labour, the extent of the market and a decrease of the proportion of the population needed to provide basic social services, such as military and political security, so that relatively more manpower would be available for other purposes.<sup>565</sup>

227. However, a country that is already assured of most of the benefits of the economies of scale through the mere size of its population will profit little from the further growth of population. A nation with a high growth rate and a population that is already large in absolute terms cannot expect that further increases in its size will mitigate the economic disadvantages of population growth by providing economies of scale, according to some views. Spengler noted the economic limitations to the division of labour and other factors involved in economies of scale,<sup>566</sup> and similar conclusions were reached by other writers.<sup>567</sup> The existence of increasing returns to scale may be more likely, it has been argued, in the economically advanced countries where primary production, in which diminishing returns may be most important, represents in most cases a small part of total output and where technological progress and economies of scale are "built-in" in the economies.<sup>568</sup> By a similar reasoning, it might be assumed that a declining population would cause diseconomies of scale, but definite conclusions in this respect do not appear to be possible.<sup>569</sup> Contrary to the developed countries, diseconomies of scale may be more typical for developing countries when population is

<sup>564</sup> Sauvy, "Croissance de la population et productivité" (1963).

increasing. The arguments against the advantages of high rates of population growth in view of possible economies of scale are especially strong in developing countries that are small in size and have relatively limited natural resources. In these countries, any advantage of economies of scale resulting from a larger population tend to be balanced by diminishing returns due to an increasing relative scarcity of natural resources. Such tendencies could be countered either by a faster accumulation of capital or an expansion of external trade.<sup>570</sup>

(d) *Population growth, human capital and productivity*

228. Recent literature has emphasized the shortcomings in envisaging economic growth predominantly as a function of the mere amounts of capital or land. As it became clear that the long-term trends in economic growth could not be explained in terms of these conventional factors, the literature has given an increasing emphasis to other determinants of economic growth and among these the role of human capital has come to be considered as one of the most important.<sup>571</sup> The traditional concepts of capital and resources are accordingly extended to include human capital and resources, which are thought to be a crucial factor in the performance and progress of the economy and society. Expenditures on education, health and the promotion of mobility contributing directly to the knowledge, skills, capacity and availability of the country's population are, in the view of many writers, investments which greatly improve the quality of human effort and its productivity.<sup>572</sup> In terms of their contribution to economic growth, these investments, it is contended, are at least as important as other forms of capital and resources, or even more so.<sup>573</sup>

229. The concept of human capital may be defined in various ways. In general terms, it has been said to include the skills, aptitudes and acquired traits that contribute to higher production and productivity.<sup>574</sup> More specifically, the following types of investments in human capital have been distinguished: formal education at different levels; on-the-job training and apprenticeships; study programmes for adults and self-development; improvements in health, including those that increase the life expectancy, strength, vigour and vitality of the population; improvements in nutrition; and measures stimulating migration so that the supply of labour adjusts itself

<sup>574</sup> Goode, "Adding to the stock ..." (1959). On the problem of definition see also Debeauvais, "The concept of human capital" (1962).

to changing job opportunities.<sup>575</sup> Among these different categories of human capital, education is often singled out, and many authors have stressed the importance of knowledge, skills and training of the working force for productivity.<sup>576</sup>

230. Whereas expenditures on education may be considered as consumption as well as investment, it is the latter aspect which is emphasized in human resources development. Nevertheless, in practice it may be difficult and, according to some authors, virtually impossible to distinguish between the two and it is for this reason that the calculation of the rate of return on educational programmes in the same way as that of investment in physical capital is thought to be very difficult.<sup>577</sup> In addition, the acquisition of skills and knowledge through education and various forms of training is not without cost. Apart from the direct expenditures, the cost of education also involves the earnings which students forgo when they continue their schooling after the time they could have entered the working force and, it has been asserted, that this latter category constitutes probably the most important cost element.<sup>578</sup>

231. While, in general, investment in human and physical capital complement each other, in a more immediate sense they compete with each other, the more so since investments in human capital are not directly productive, and thus tend to lower the rate of return on investments in the short run, even though in a longer time perspective they are a basic requirement for economic development and may give a high rate of return both for the individual and society.<sup>579</sup> Nevertheless, where resources are scarce, investments in education and human capital may suffer. It has been noted, for instance, that earnings forgone may be an important factor in reducing the schooling of children of low-income and rural families and in increasing the rate of drop-outs.<sup>580</sup>

<sup>580</sup> Schultz, *The Economic Value of Education* (1963), p. 6.

232. In general, the implications of population growth for the formation of human capital have not as yet been fully explored. In general, it has been said that the question of numbers is at the root of the human resources problem,<sup>581</sup> and that if population grows rapidly and savings are not high enough to satisfy both the demand for investment in education or human capital and the requirements in terms of physical capital, then the levels of productivity, employment and economic progress are bound to suffer.<sup>582</sup>

#### (e) *Population growth, technological progress and productivity*

233. The role of technological progress and change in the process of economic growth and development has been widely recognized.<sup>583</sup> In its turn, population growth may be ranked among those factors which play a role in determining the level and rate of technological change. While a rapidly growing population and labour force is commonly believed to raise the problem of the choice of techniques and to contribute to the introduction of new techniques or wider use of existing ones,<sup>584</sup> population growth and the demographic trends associated with it are also thought to affect or induce technological progress in a direct manner.

234. The concept of technological progress is not easily defined; in general terms it may be described as the process by which output increases with the same factors of production and, particularly, labour. Or it may be considered to encompass those changes which increase the productivity of the available factors of production.<sup>585</sup> As such, technological progress is intimately related to the increase in knowledge, but in discussing the process a distinction is usually made between invention, in the sense of a discovery or development of a new technique and innovation and the application and utilization of the new techniques in the production process.<sup>586</sup> As far as the nature of technological progress is concerned, it is classified, as a rule, as labour saving, capital saving or

neutral. The first two of these imply, as their names suggest, a technological change with a saving in either labour or capital compared to the other. While neutral technological change suggests an equal saving of both factors, its exact nature is not unambiguous, and a number of different definitions of this concept have been proposed.<sup>587</sup>

235. Technological progress is determined by a large number of factors, among them the increase of pure knowledge; research and development; market organization; entrepreneurship and so forth, but little is known as to whether or how these aspects are affected by demographic factors. A possible indirect effect of population growth in this respect, however, has been pointed out by Kuznets, who argued that population growth would produce a larger number of exceptionally talented and gifted individuals who, assuming the necessary resources for education and training, would contribute to a more rapid increase in the stock of useful and applied knowledge which, in Kuznets's opinion, is the most important factor in the growth of *per capita* output.<sup>588</sup>

236. It is a more or less generally accepted proposition that the direction and extent of inventive and innovative activities are influenced by relative factor scarcities and thus indirectly by demographic factors, especially the size and rate of growth of population relative to land and capital. Particularly on the basis of the experience of the economically more developed countries, it has been argued that a scarcity of labour induces the development and introduction of labour-saving techniques. Profit maximization, it is argued, leads firms to direct innovative activities towards techniques which save on the most slowly growing factors.<sup>589</sup> The assumption that the growth of the active population or employment dominates the choice of techniques, either directly or indirectly through capital accumulation, is often also implied in theoretical or empirical studies.<sup>590</sup> Analogously, it is sometimes held that in those developing countries where labour is abundant, a pressure may exist to use more capital-saving techniques.<sup>591</sup>

<sup>587</sup> For different definitions of neutral technological progress, see, for instance Pigou, *The Economics of Welfare* (1932), pp. 632-638; Harrod, *Towards a Dynamic Economics* . . . (1948; 1963 ed.), pp. 24-25; Robinson, *Essays in the Theory of Employment* (1947); Solow, "Technical change and . . ." (1957); Meade, *A Neo-Classical Theory of Economic Growth* (1964).

(1965), p. 137; Buchanan and Ellis, *Approaches to Economic Development* (1955), p. 46; Sauvy, *Théorie générale de la population*, vol. 2 . . . (1959). Habakkuk, "Population problems and European economic development . . ." (1963), argued that an abundance of labour provides more opportunities for trying out new methods of production and leads to a more rapid absorption of existing technical knowledge.

237. Various writers have discussed in more general terms the role of population growth in technological progress. Dupréel, in his theory, asserted that population growth tends to raise levels of living through the effect it has on the augmentation of social mobility and personal contacts which serve as stimuli, a more optimistic and enterprising climate of expectation, and through the direct effects it has on the intensification of the rate of technological progress and innovation. These and other effects, in his opinion, would more than offset any adverse consequences of population growth.<sup>592</sup> In a recent study, population increase was directly related to agricultural techniques in pre-industrial economies. An analysis of techniques used under different fallows systems as applied in primitive agriculture revealed, the study suggested, that population growth was a major determinant of technological progress. The underlying assumption was that at low levels of development the agricultural techniques in use were those that required the least effort for the highest yield per man-hour—such as forest fallows. As population increased, the possibilities for continuing such techniques of extensive cultivation became more limited and a change of techniques, or a shift to a different system, was inevitable. Such changes, it is argued, took place only under population pressure, and not spontaneously, because output per man-hour was highest under systems of extensive cultivation. Output per worker, however, would probably increase, as under more intensive cultivation caused by population pressure, the input of man-hours would increase more than productivity per man-hour declined.<sup>593</sup> The thesis that the growth of population and the increased pressure on levels of living it caused would call forth a reaction against the possibility of such a decline was advanced by Hirschman. He argued that population pressure on levels of living would lead to activities aimed at maintaining or restoring the traditional levels of living and such activities would induce an increased ability to control the environment and to organize the society for its subsequent development. Although he recognized that as an inducement mechanism, population pressure is among the least desirable ones, he nevertheless held that it presents the developmental forces with an opportunity to assert themselves.<sup>594</sup>

238. Certain reservations as to the effects of population growth on productivity have been formulated by a number of writers. Schumpeter, who stressed the role of the *entrepreneur* in economic growth, affirmed that by itself an increase in population often would have no other effect than to depress levels of living, although in conjunction with technological progress, it might be a powerful driving force for economic growth.<sup>595</sup> Whereas many authors agree that population growth may in principle lead to technological change favouring more labour-intensive techniques, they express doubts for several

reasons as to the practicability of such a solution. In the first place, it is argued that most innovations originate in the already developed countries where labour, rather than land or capital, is the scarce factor. Hence new techniques in the developed countries mainly tend to be labour-saving and capital-using, while the opposite are needed in the developing countries.<sup>596</sup> Alternatively stated, population growth, by keeping the population-resources ratio high, mitigates against the introduction of advanced production methods, especially where modern technology is embodied in the capital equipment. Although it does not make impossible the introduction of modern technology in developing countries, rapid population growth, it is asserted, tends to weaken the possibilities and incentives to do so.<sup>597</sup> Sauvy listed, among the conditions under which the economy and productivity would adapt itself to population growth, the fact that demographic growth must be gradual and progressive and that a certain stage of development should already have been attained.<sup>598</sup>

239. In addition to the factors discussed, population growth may affect technological progress indirectly through the structure of the stock of capital and the flexibility of the labour force. As far as the first of these two factors is concerned, it has been argued that the aggregate stock of capital, given other conditions, will grow faster when the rate of population growth is higher. Consequently the average age of capital will be lower and a larger fraction of it will incorporate recent knowledge and advanced technology.<sup>599</sup> As far as the adaptability of the population growth to technological change is concerned, the argument is that population increase facilitates the structural and occupational changes required by technological progress. A stationary population will have fewer new entrants into the labour force and it is especially young workers who adapt themselves more easily to changing employment opportunities.<sup>600</sup> However, both these arguments appear to be fully valid only in the developed countries, where capital is not a scarce factor and population and labour force growth is moderate rather than high.

#### 4. INTERNATIONAL MIGRATION AND PRODUCTIVITY

240. As discussed earlier, migrations from one country to another respond, in many cases, to the economic opportunities assumed to exist in the country of destination. To the extent that such expectations on the part of the emigrants are fulfilled, their levels of income and productivity will be higher than before migration. The implications of emigration and immigration for the overall levels of productivity in the countries of origin and destination, respectively, depend, however, on a number of factors. Among these are the effects on the relative scarcity or abundance of labour as compared with other factors of production, including the skills and training of the migrants; on the possibilities of factor substitution, resource use and capital formation; on economies of scale; and on technological change.

241. Since immigrants, in many cases, are males of working age, immigration by increasing the relative size of the economically active population will tend to raise income per person, though not necessarily income per worker. The latter might be expected to occur where international migration brings about a more efficient combination of factors of production. In countries of immigration, the inflow of workers will lead to a higher productivity when labour is scarce in comparison with other factors of production. In countries of emigration, such an effect would result if unemployment or underemployment existed or, more generally, if the relation between labour and other resources, and especially the capital-labour ratio, would improve.<sup>601</sup> It has been pointed out that in considering these effects of emigration and immigration on production and productivity, labour cannot be considered as homogeneous and that allowance must be made for the qualifications and skills of the migrants and the complementarity between different types of labour. If, in countries of emigration, the supply of qualified labour is limited, even though general unemployment is high and productivity low, emigration of the former would be likely to result in even higher unemployment and lower productivity.<sup>602</sup> Although less probable, in principle a similar effect might occur in countries of immigration if large numbers of unskilled immigrants would cause or increase a shortage of qualified workers.

242. Migration may lead to a number of substitutive and complementary effects in countries of emigration and immigration which may affect productivity adversely in some cases, positively in others. Immigration will tend to lower the capital-labour ratio, make capital services more expensive, compared to labour, and cause wages to decline. Emigration is likely to have the opposite effects. Consequently, in countries of immigration, capital will be used more intensively per unit of labour or, alternatively stated, labour will be substituted for capital. The importance of such an effect depends, however, on the qualifications of the labour force, the type of industry

<sup>601</sup> Spengler, "Effects produced in receiving countries ..." (1958); International Labour Office, *International Migration, 1945-1957* (1959), pp. 363-364; Reder, "The economic consequences of increased immigration" (1963); Zolotas, "La migration internationale des travailleurs ..." (1967).

<sup>602</sup> Isaac, *Economics of Migration* (1947), pp. 203-204.

and, more generally, the technical possibilities of factor substitution. If the immigrant labour is unskilled, it may be argued that less capitalized and more labour-intensive industries can absorb more immigrant labour comparatively easily because their expansion requires less investment, and these industries will respond more to a fall in wage rates caused by immigration. The absorption of immigrant labour in highly capitalized industries will not only require much larger investment outlays; in addition, since in these industries the wage rate has only a small effect on the production costs and the possibilities of introducing more labour-intensive methods of production take longer because of the existing bulk of equipment, the response to a decrease in the wage rate is likely to be small.<sup>603</sup> Although various writers, in general, contend that substitution of factors of production may be likely in the case of immigration and emigration,<sup>604</sup> others have argued that possibilities of substitution are in both cases limited in view of the complementarity of factors of production and the limited technical possibilities for substitution.<sup>605</sup>

243. Indirectly, international migration may affect *per capita* income and productivity through the effect it has on the utilization of natural resources, investment and labour-force participation. As noted, an increased labour supply through immigration may reduce the real wage rate and increase the rate of return on capital. This in turn, it is asserted, would increase the incentives for capital formation. In countries of emigration, the opposite is assumed to take place; to the extent that the supply of labour becomes scarce and real wages increase, the marginal productivity of capital will decline and, in so far as the latter determines investment, so will capital formation.<sup>606</sup> Whether these effects of immigration and emigration would compensate respectively for the increased and the diminished product per worker caused by the original change in factor proportions following the migration cannot easily be determined.<sup>607</sup>

244. Immigration by increasing the size of the population may create, according to some, economies of scale. By enlarging the size of a country's market, immigration provides opportunities for the division of labour and industrial differentiation which may affect some of the increases in costs resulting from immigration.<sup>608</sup> In addition, if immigrants engage in the country of immigration in activities complementary to those of the country of emigration, international migrations may give rise to

an increased international specialization and division of labour which, it is argued, could benefit both countries of emigration and immigration.<sup>609</sup> However, it has also been asserted that international migration does not necessarily contribute to the international division of labour, but rather that it may lead to a more efficient combination of the factors of production.<sup>610</sup> It has also been argued that emigration tends to improve a country's terms of trade, whereas immigration tends to lead to their deterioration.<sup>611</sup> In this connexion it has also been noted that if goods could be moved freely and without transportation costs and certain other conditions were realized, international trade could equalize both prices of goods and those of labour. Although such conditions are unlikely to be found in practice, it is nevertheless held that, within limits, international trade could be a substitute for international migration.<sup>612</sup>

245. International migration can in a number of ways contribute to technological progress and knowledge. Immigration of technical and other skilled labour will by itself improve the stock of technical knowledge. Even unskilled labour may affect the state of techniques if, as a result of the immigration of unskilled labour, the wages of such workers would decline. Under these conditions new inventions and processes might be developed to substitute unskilled for other labour.<sup>613</sup> However, the view has also been advanced that the abundance of unskilled labour resulting from immigration could hold back technological progress. The argument is that it discourages the development of labour-saving techniques which might evolve if a labour shortage were to exist.<sup>614</sup> Immigration into the United States accompanied by the import of capital is thought to have been an important factor in bringing about a technological transformation during the late nineteenth and early twentieth centuries.<sup>615</sup>

246. International migration may affect productivity indirectly in a number of ways. It is usually assumed that international migration is selective as far as the character of the migrants are concerned, so that among migrants there is a high proportion of individuals who are willing to take risks, and who have initiative, entrepreneurship and so forth. Immigration is also said to increase the mobility of the population. The degree of mobility of the working population, in particular, would increase if the occupational composition of the immigrants were different from that of the labour force of the country of

immigration or when immigration facilitated fundamental changes in the occupational structure.<sup>618</sup>

##### 5. INTERNAL MIGRATION, URBANIZATION AND PRODUCTIVITY

247. The links between internal migration and urbanization, on the one hand, and levels and trends of productivity, on the other, are strong. These interrelations derive from the close association between the redistribution of population and the changes in the structure of the economy as one of the most important correlates of economic development. Internal migration determines, but is also determined by, the process of structural and geographical change of the economy, its development and increases of levels of living and productivity. Nevertheless, this interdependence between such changes in the economy and the geographical distribution of the population does not imply of necessity a balance between the two. The lack of such a balance is an important additional factor in the effects of internal migration on productivity.

248. Internal migration, like international population movements, is thought to respond to a large extent, although not exclusively, to economic opportunities. Since internal migration is predominantly a movement towards areas with greater earning opportunities, such migrations are important factors in productivity increase and economic growth. By accelerating the shift of labour from activities characterized by comparatively low productivity to others with higher productivity, the migration of labour raises the productivity of the economy as a whole, even if that of individual activities remains constant.<sup>617</sup> It has been observed, however, that internal movements of labour, as well as capital, do not lead, as is often assumed, to a reduction of inequalities in income and productivity. Internal migration, it is argued, generally has a high degree of selectivity, especially with respect to age. Out-migration, by reducing the proportion of young workers, not only affects the dependency ratio but also the productive capacity of the remaining population, since it is likely to be more tradition-oriented and with less initiative.<sup>618</sup>

249. Among the different forms of internal migration, rural-urban movements are as a rule the most important, both in volume as well as in their effect on levels of productivity. The geographical concentration of economic activities in urban areas creates the economies of scale which are a basic characteristic of modern industrial and

related activities. Levels of urbanization, therefore, are not only an index of economic and social development but also a stimulus to change. Rural-urban migration is a condition for large-scale economic expansion and development, thus implying increasing levels of income for the population transferring from less productive pursuits to urban employment and increased productivity for the population as a whole.<sup>619</sup>

250. However, a number of authors have pointed out that in many developing countries factors may be at work which cause levels of rural-urban migration to increase beyond the absorptive employment capacity of the city. "Over-urbanization" in this sense is ascribed mainly to the pressures of population on natural resources and the high levels of underemployment in rural areas which act as "push" factors. A too rapid urbanization, which is the consequence of this "push" from rural areas instead of the "pull" exerted by urban demand, will affect economic progress in a number of ways, according to these views. Implying an excessive supply of labour, the workers thus affected will find employment only in activities with low productivity, or become unemployed. The rapid urbanization, in addition, will require economic and social infrastructure investments, and this demand for the less directly productive projects will absorb a considerable part of the already scarce capital resources. Excessive urbanization, therefore, it is concluded, will hold back economic development and rapid increases in productivity.<sup>620</sup>

251. These views, however, have not been generally accepted. While it is granted that migrants are often absorbed in low productivity employment, the argument is advanced that nevertheless such employment is more productive than the rural work. Also, it is thought that the infrastructure investments would have to be made anyway and that in urban areas they are more productive than in the countryside.<sup>621</sup> More generally, the viewpoint has been advanced that over-urbanization has its limits, and that unless the demand for urban labour is increasing rapidly, large shifts to the cities caused by push factors are unlikely. Also to the extent that cities are the locale of modern, highly productive activities, the concentration of population in urban areas constitutes a potential and stimulating factor for economic change and progress.<sup>622</sup>

## 6. DEMOGRAPHIC AND NON-DEMOGRAPHIC DETERMINANTS OF PRODUCTIVITY

252. The foregoing considerations of the effects of demographic factors on productivity suggest in general terms that population size, growth and characteristics may be significant factors in determining the levels of productivity and of the performance of the economy as a whole. However, the exact extent of the implications of population factors for economic growth and development are still far from clear, partly because of the complexity of the problems involved.

253. Much of the discussion on this subject has centred around the effects demographic factors have on productivity by means of the availability of factors of production and the existence of different techniques. Various of the conclusions concerning the implications of other factors of production have to be, at least in part, modified if the possibility of a choice between different techniques is taken into account. Nevertheless, the view that ultimately this does not fundamentally change the finding that pressure of population on other resources tends to depress and retard levels and rates of economic growth and development appears to be supported, at least in theory.

254. Knowledge of the direct influence which demographic factors exert on technological progress and other intangible determinants of economic growth is extremely limited. Some factors, such as population size and growth and age distribution, might create conditions favourable for economies of scale, the introduction of new techniques and so forth. However, the extent to which demographic factors do actually, as opposed to potentially, contribute to raising levels of productivity, in general, is difficult to establish. In view of the large number of determinants which affect the levels of performance of the economy in this respect, it may be doubted whether the effects of demographic factors are predominant. However, it may be argued that their potential significance justifies a more penetrating and more exhaustive analysis than has been attempted so far, even though, as the existing literature already suggests, an exact assessment and appraisal of the demographic factors as determinants of productivity and economic progress may be found to be impossible.

### E. Some principal interrelations

255. Over the last decades, there has been an impressive increase in the literature on the interrelations between population and economic growth and development. The major factor in this evolution has been the widespread preoccupation with the problems of economic progress in the developing countries, on the one hand, and their demographic trends and characteristics, on the other. No doubt large gains have been made in the understanding of these complex processes and their interaction. But despite this better insight into the demographic-economic interrelations, acquired in the recent past, this knowledge is as yet far from exhaustive and substantial gaps remain, at least as far as the demographic aspects of economic

growth and development discussed in this chapter are concerned.

256. Among the interrelationships between demographic factors and determinants of economic growth which have been most exhaustively discussed are the effects of population growth and age composition on the rate of savings and investments. The basic argument is that to the extent that consumption needs of the individual vary with his age, the age composition of the population is thought to be an important factor in determining total consumption needs and thus, for a given income, the residual which can be saved. Firm evidence, even though of an indirect nature, on the effect of the age distribution on consumption has, however, been provided especially through studies of the consumption levels and patterns of households and families. The results of such analyses generally confirm that, other factors being equal, a decrease in saving capacity occurs as the size of the family, and particularly the number of children, increases. The further development of this approach and the incorporation of family life cycle analyses in it might, it appears, contribute substantially to a better understanding of the effects of age composition on capital formation. However, such studies would relate mainly to the effects of the age structure on savings by households; they would add little to the knowledge concerning its implications for capital formation in the public sector, an area which despite its growing importance even in the non-socialist countries, has not been extensively explored.

257. The influence of population growth on consumption and, particularly, investment is evident. Granted that the maintenance of existing levels of living is a minimum requirement, the rate of population growth sets a lower limit to the expansion of consumption. A similar reasoning applies to the case of investment and, because of the problems of capital scarcity facing many developing countries, the high investment needs created by the rapid rate of expansion of the population in these countries has been extensively discussed in demographic literature. On the basis of so-called Harrod-Domar models it has been shown that, depending on the value of the capital-output ratio, demographic investments, that is those required to maintain existing levels of living, may absorb the larger part of a country's investments, leaving little room for increasing capital per worker, productivity and income, or even may require more than the country's total investment funds. Even so, it has been generally acknowledged that this interpretation places an undue emphasis on capital formation as the determining factor of economic development, ignoring the contribution of human resources and other less tangible factors.

258. Population and the economy are closely linked through employment. The size, growth and composition of the population are among the basic determinants of the supply of labour whereas economic growth, structure and production relations underlie its demand. Much of the demographic literature on this subject has stressed the typical age distribution of developing countries, with its large proportion of children and consequent heavy dependency load, as an important factor making for reduced productive capacity of the population. In more

general terms, given the production relations, the extent to which the labour force can be efficiently absorbed in the economy depends on the relative abundance or scarcity of the complementary resources—land and, particularly, capital. The existing literature has extensively discussed the implications of a high labour-land ratio with its consequent pressure of population on natural and agricultural resources. In the view of many, though not all writers, such a pressure of population on the land, especially in subsistent, peasant economies, is the basic cause of high levels of underemployment and underutilization of the productive capacity of the working population. As opposed to population size, high population and labour force growth rates, associated with low or insufficient rates of capital accumulation, are held to be a major cause of high levels of unemployment and underemployment, especially in the developing countries.

259. Apart from their implications for such determinants of economic growth as savings and investments, and employment, demographic factors may influence in a number of ways the performance of the economy, as measured in terms of productivity. Partly due to the complex nature of productivity and its determinants, the effects of the population variables cannot be easily assessed. In general terms, it has been recognized that population size, growth and composition may affect such diverse determinants of productivity as the factor proportions and methods of production; the structure of the economy and changes in it; specialization and economies of scale; innovations and technological progress, the skills and qualifications of the labour force etc. Nevertheless, many of these interrelationships are only imperfectly known or have only partly been explored. For instance, it is only in the past decade that the effects of population size on economies of scale has begun to be systematically studied; it has only recently been pointed out that the problems of development of the "dual economy" are to a great extent due to population growth; it may be argued that the role of population and factor scarcities on invention and innovation have been barely touched upon.

260. It appears that the need for more knowledge is particularly urgent in these latter fields, not only because

of the limited present understanding, but also because of the fundamental role of the productivity factor in economic growth and development. Whereas the theory of economic growth has gone through different stages in which first natural resources and then capital formation were thought to be the crucial factors in development, at present the predominant view, although not generally accepted as yet, is that the basic explanation of economic development must be sought in those intangible factors which may be summarized under the heading of productivity increases. It is mainly for this reason that further research on the demographic aspects in this field should be undertaken also, to permit an exhaustive assessment of their role in economic, as well as social, development.

261. In this chapter only the implications of the basic population variables for the principal determinants of economic growth have been considered. A complete evaluation of demographic-economic interrelations would require the integration of the subject-matter dealt with here with the analysis of the influence of economic factors on demographic variables, discussed in previous chapters of this study. To the extent that the findings of the present chapter provide a basis for a conclusion, it appears that demographic characteristics intermediate between those associated with extremely high or extremely low population growth would be most conducive to rapid economic growth and development. Even though this chapter has been concerned predominantly with the implications of the demographic situation and characteristics for developing countries, on the grounds that in these countries demographic obstacles to economic growth loom largest, the literature concerning the implications of low population growth in the more developed countries on economic growth suggests, even though the stagnation theory may have been exaggerated in this respect, that a virtually stationary population may severely limit the rate of economic growth. Under prevailing conditions in both developed and developing countries and within a limited time perspective, moderate population growth and a balanced age, geographical and occupational distribution probably provide the most favourable combination of demographic factors for rapid economic growth.

## Chapter XIV

### DEMOGRAPHIC ASPECTS OF MODERN ECONOMIC GROWTH

1. For the greater part of its history, mankind was sustained only precariously by the means of subsistence at its disposal. Even though in the long run some improvements in living conditions did materialize, in many cases they were barely noticeable or else they mainly benefited the privileged classes. Over shorter periods, any increase more than minimal in the levels of living of the masses or in the number of people was as likely as not soon to be wiped out. Only in the course of the last two centuries has it become evident that a marginal existence for the population as a whole is not inevitable. The modern period has seen a striking acceleration in the rate of economic growth, while witnessing at the same time an unprecedented increase in population. But even now modern economic growth is a process limited to only a relatively small part of the world. Comparisons of income or other indicators of levels of living of different countries reveal large inequalities between the wealthy developed minority and most of the less developed rest of the world. However, the awareness of this gap between the rich and the poor nations and the conviction that rapid economic growth of the latter is both possible and desirable are widespread and underlie the determined efforts now being undertaken by these countries to promote their economic development.

2. Rapid economic growth in comparison with earlier periods is only one of the revolutionary changes which has affected man and society in the modern period. As noted, it has been accompanied by and closely associated with another aspect of change, the emergence of new demographic trends. Whereas in earlier periods population was ultimately held in check by the slow and discontinuous improvements in food supply, since the beginning of the modern period the number of people has grown continuously and faster than ever before. While the initial impetus to this demographic expansion has taken place in the presently economically developed countries, it has gradually spread to the rest of the world and a rapid population growth has also become typical of most of the less developed countries. In fact, demographic trends in the latter group of countries has become by far the most important factor in the extraordinary growth of the world's population in the last few decades. Population in many of the developing countries has increased at rates never experienced before in the world's history, causing a considerable further speeding-up of the accelerated growth of the world's population, which has been one of the predominant characteristics of modern times.

3. Although it is generally acknowledged that economic and demographic change during the period of modern

economic growth have not been independent of each other, the exact nature and extent of the relationship between them remain still largely unknown. While this lack of knowledge may be attributed in part to a less than satisfactory exploration of these interrelations as they have manifested themselves and to the scarcity of data in this field, the fundamental reason lies in the nature of the relationships. Population and economic change are not the result of a simple cause and effect mechanism between the two. Both economic performance and demographic patterns are ultimately governed by a complex of social, cultural, political and psychological factors which shape the society's institutions and development and the behaviour of its individual members, and their interrelations are the outcome of a complicated system of interdependence between a large number of variables and factors which include not only the economic and demographic factors, but also many others. Associations between economic growth and demographic trends during the period of modern economic growth, reflecting this indirect nature of the interrelationships, have proven to be neither invariable nor equally significant at different times and under different circumstances. Even so, knowledge of such associations as exist and have existed are an indispensable element for a better understanding of the underlying relationships and, ultimately, the conception and formulation of appropriate policies.

4. The purpose of the present chapter is to review the over-all associations between population and economic growth as they have manifested themselves during the modern period. The chapter is mainly concerned with the state of knowledge of these interrelations at a relatively general level and with major emphasis on only the most fundamental economic and demographic variables, including growth of product and income and structural change in the economy, population growth, fertility, mortality and urbanization. Although the variety of experience in economic and population growth is discussed, an analysis of trends, past or present, in individual countries is not included. The chapter also excludes the consideration of those social and socio-economic aspects, such as employment, distribution of income, education, health, and so forth, which have come to be accepted as an integral part of the development process and are increasingly recognized as being affected by demographic factors and trends. Following a brief discussion on the definition and characteristics of economic growth in the first section (section A), the subsequent sections deal, respectively, with general aspects of economic and demographic trends in the modern period (section B) and with a more detailed analysis for recent years with special

reference to the more and less developed countries (section C). The final section (section D) is concerned with the historical experience of the more developed countries and its relevance for the countries presently in the process of development.

#### A. Economic growth: definition and manifestations

5. The problem of how to define or, in a broader sense, select the most appropriate indicator of economic growth and of the level of economic development has been widely discussed in economic literature. Many authors hold that the increase of real income or product, or preferably of income or output per head, is the best single, albeit incomplete, measure of economic growth.<sup>1</sup> Others, however, have expressed doubts about the adequacy of the income criterion or rejected the suggestion that it may be used as an index of economic growth or the level of economic development.<sup>2</sup> Despite the shortcomings of the income concept, economic growth is identified, in general, with the realized capacity of a country's economy to generate significant increases in *per capita* product or income.<sup>3</sup>

<sup>1</sup> Leibenstein, *Economic Backwardness and Economic Growth* ... (1957), pp. 7-14; Rostow, *The Process of Economic Growth* (1960), p. 81; United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1961*, part II ... (1965), chap. 1, pp. 3-4. Piatier, *Equilibre entre développement économique* ... (1962), p. 7; Peterson, *Income, Employment and Economic Growth* (1962), pp. 459-461; Mellor, *The Economics of Agricultural Development* (1966), pp. 11-16. Bruton, *Principles of Development Economics* (1965), pp. 1-2. Even most of those writers who suggest the use of the income criterion as a measure of economic growth and development recognize the limitations inherent in a single index for measuring such a complex phenomenon as economic growth and the weaknesses of income as such a measure, including especially its failure to reflect the distribution of income.

<sup>2</sup> Clark, "Common and disparate elements ..." (1949); Viner, *International Trade and Economic Development* (1953), pp. 125-129; Frankel, *The Economic Impact on Underdeveloped Societies* ... (1953), pp. 29-55; Abramovitz, "The welfare interpretation ..." (1959, 1965); United Nations, Economic Commission for Asia and the Far East, *Economic Survey of Asia and the Far East, 1961* (1962), pp. 7-8. Much of the criticism of the use of the income concept for the purpose of measuring economic growth and economic development centres on the fact that, as an indicator of well-being, it is too narrow and the use of indices of levels of living which encompass various aspects—some measurable, others not—of well-being has been proposed as an alternative. Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 5-18; Coale, "Population and economic development" (1963); Fourastié, *La civilisation de 1975* (1967), pp. 13-39. For a list of indices of levels of living see United Nations, *Report on International Definition and Measurement of Standards* ... (1954) and *International Definition and Measurement of Level of Living* ... (1961). For the application of a number of indices of levels of living to different countries see Bennett, "International disparities in consumption levels" (1945). The argument against the use of indices of levels of living as a measure of economic growth is that the latter is a more restrictive concept than increase in well-being and that, in any case, material well-being will depend to a large extent on the amount of goods and services available.

<sup>3</sup> Kuznets, *Toward a Theory* ... (1965), p. 6, used a broader definition adding as a characteristic of economic growth "sustained increases in the population", his argument being that a definition must reflect common experience and that modern history has rarely revealed cases where increases in *per capita* income had been associated with a secular stagnation or decline in population. In his *Modern Economic Growth* ... (1966), p. 19, he added increases in product per worker to increases in *per capita* product. Clark, *The Conditions of Economic Progress* (1957) preferred the increase

6. Even so, the process of economic growth involves much more than increases in total or *per capita* income. Based on the spread of empirical science and knowledge and their application in the sphere of production, economic growth as it has emerged in the course of the last two centuries has been associated with profound changes in the organization, functioning and structure of the economy and the society. One of the fundamental transformations accompanying the development process is the changing industrial distribution of the labour force and product, with the shift from agricultural to non-agricultural activities.<sup>4</sup> At the source of this process of structural change are the forces of demand and supply set in motion by the increased productivity and technological progress as the main causes of economic growth.<sup>5</sup> The low income elasticity of demand for food and primary products, reflecting the nature of human wants, implies a shift in demand away from these goods as levels of income rise, while the demand for less essential manufactured goods and services will account for an increasing share of income. On the supply side, higher productivity, together with the relative decline in the demand for agricultural products, creates the conditions for the release of resources, especially labour, from agriculture and their absorption in the expanding non-agricultural activities.<sup>6</sup> Technological progress will not only stimulate the growth of the non-agricultural sectors by creating new production processes, but also new consumer goods, the demand for

in real income per man-hour as a measure of economic growth to that of increase per person. See, also, United Nations, Economic Commission for Asia and the Far East, *Economic Survey of Asia and the Far East, 1961* (1962), p. 9. In the socialist countries the basic concept used for measuring economic progress is the Net Material Product (N.M.P.). Economic advancement in these countries is in general denoted as the rise of productive forces for the measurement of which a set of indicators, most of them indices of the volume of physical production, is applied. Notkin, "Tempy ekonomicheskoy razvitiia SSSR ..." (1961).

<sup>4</sup> The changes in the industrial distribution of the labour force are said to have been observed first by Petty in the seventeenth century. Recent pioneers in this field were Fisher, Clark and Fourastié. See, for instance, Fisher, *The Clash of Progress and Security* (1935); his "The economic implications ..." (1935) and his "Production, primary, secondary and tertiary" (1939); Clark, *The Conditions of Economic Progress* (1957); Fourastié, *Le grand espoir du XX<sup>e</sup> siècle* (1949). See also Lewis, *The Theory of Economic Growth* (1963), pp. 334 ff.; Leibenstein, *Economic Backwardness and Economic Growth* (1957), pp. 77-93; Sauvy, *Théorie générale de la population*, vol. 1 ... (1956), pp. 115-117; United Nations, *World Economic Survey, 1961* (1962); Peterson, *Income, Employment and Economic Growth* (1962), pp. 504-510; Kuznets, *Toward a Theory* ... (1965), pp. 24-29 and *Modern Economic Growth* ... (1966), chap. 3; Johnston, "Agriculture and structural transformation ..." (1970).

<sup>5</sup> As a number of writers have pointed out, increases of productivity within each of the industrial sectors and not the changes in the industrial structure are the principal determinants of economic growth. See Lewis, *The Theory of Economic Growth* (1963), p. 340; Kuznets, "Quantitative aspects of the economic growth of nations. II ..." (1957) and his "Consumption, industrialization and urbanization" (1966).

<sup>6</sup> Clark, *The Conditions of Economic Progress* (1957); Fourastié, *Le grand espoir du XX<sup>e</sup> siècle* (1949) and his *Machinisme et bien-être* (1951); Lewis, *The Theory of Economic Growth* (1963), p. 334; Chenery, "Patterns of industrial growth" (1960); Peterson, *Income, Employment and Economic Growth* (1962), p. 509; Nicholls, "The place of agriculture ..." (1964); Kuznets, *Toward a Theory* ... (1965), pp. 25-26, 29 and his *Modern Economic Growth* ... (1966), pp. 113-114, 120-121.

which creates an additional factor in the shift away from agriculture.<sup>7</sup>

7. The structural shifts in favour of non-agricultural activities are evident in the sectoral shares of national product, and probably also capital stock, but manifest themselves most clearly in the distribution of the labour force and its movement from agriculture or primary production to the non-agricultural secondary and tertiary activities.<sup>8</sup> It is for this reason that the industrial composition of the labour force is sometimes considered an appropriate indicator of the level of economic development.<sup>9</sup> The process of structural transformation implies a reduction in the share of the agricultural labour force from as much as four fifths in the pre-industrial stage to as little as one tenth or even less at an advanced stage of development. As part of this evolution, often referred to as the process of industrialization, the shares of secondary and tertiary employment increase, although not necessarily at the same rate. Once a certain stage of development has been reached, secondary employment may stabilize or decline somewhat in relative terms while tertiary employment may continue to expand, thus leading to a predominance of these activities in the economy.<sup>10</sup> Since these

<sup>7</sup> Kuznets, "Population redistribution, migration ..." (1964); Johnston, "Agriculture and structural transformation ..." (1970).

<sup>8</sup> No uniform and generally accepted classification of primary, secondary and tertiary activities exists. In general, primary production is thought to refer to the output of food and raw materials and includes agriculture, forestry and fishing and, but with significant exceptions, mining. Secondary production may be said to transform the raw materials into commodities and is usually understood to include manufacturing, construction and, in some cases, energy production. The tertiary activities include then all other forms of economic activities, mainly of the service type, such as commerce and distribution; transportation and communications; banking and insurance and services proper. See for instance, Fisher, "The economic implications ..." (1935) and his "Production, primary, secondary and tertiary" (1939); Fourastié, *Le grand espoir du XX<sup>e</sup> siècle* (1949), pp. 42-43, and his *Machinisme et bien-être* (1951), p. 124; Wolfe, "The concept of economic sectors" (1955); Peterson, *Income, Employment and Economic Growth* (1962), pp. 504-505.

<sup>9</sup> Peterson, *Income, Employment and Economic Growth* (1962), p. 504; Singer, "Balanced growth in economic development ..." (1960); George, *Géographie de la population* (1967), p. 51.

<sup>10</sup> Fisher, *The Clash of Progress and Security* (1935), pp. 25-31, his "The economic implications ..." (1935) and his "Production, primary, secondary and tertiary" (1939); Clark, *The Conditions of Economic Progress* (1957), chap. IX; Fourastié, *Le grand espoir du XX<sup>e</sup> siècle* (1949), pp. 40-45, and his *La civilisation de 1975* (1967), pp. 25-29. See also Lewis, *The Theory of Economic Growth* (1963), pp. 334 ff.; Leibenstein, *Economic Backwardness and Economic Growth* ... (1957), pp. 77 ff.; Kuznets, *Toward a Theory* ... (1965), pp. 24-29. For statistical analyses of the industrial structure of the labour force and its evolution, see Bean, "International industrialization ..." (1946); Clark, *The Conditions of Economic Progress* (1957); Kuznets, "Quantitative aspects of the economic growth of nations. II ..." (1957); his *Six Lectures on Economic Growth* (1959) and his *Modern Economic Growth* ... (1966). Criticism of the thesis of structural change of the labour force has been based on the difficulties of interpretation of data and on the variety of experience of individual countries. One specific reservation, especially with respect to the less developed countries, is that in these countries occupational or industrial classifications of the labour force often have only a limited meaning, given the lack of specialization and of the division of labour characteristic of primitive societies. See Bauer and Yamey, "Economic progress and occupational distribution" (1951); their "Further notes on economic progress ..." (1953) and their *The Economics of Under-developed Countries* (1957), pp. 34-40; Rottenberg, "Note on economic

changes in the sectoral distribution of employment respond not only to the changing structure of output, but also to the differential increases of the productivity of labour in the different sectors, changes in the sectoral shares of total product are in most cases less clear-cut than those in employment.<sup>11</sup>

8. One of the most important correlates of economic growth and social change, in general, and of the structural transformation of the economy, in particular, is the spatial redistribution of the population which takes the form of urbanization. The large amount of rural-urban migration occurring in response to the new patterns of spatial organization and the increasing degree of geographic concentration of economic activities is both an essential element of economic development<sup>12</sup> and an important factor and cause of social change.<sup>13</sup> Industrialization, it has been noted, means the growth of those sectors and activities which not only require little land, but are to a considerable extent dependent upon or obtain distinct advantages from conglomeration, agglomeration and size because of the possibilities of economies of scale, the division and specialization of labour and so forth.<sup>14</sup> While industrialization and urbanization are closely linked to each other and, in general, to economic development, the exact nature of these interrelations is not

progress ..." (1953); Minkes, "Statistical evidence ..." (1955); Lewis, *The Theory of Economic Growth* (1963), p. 333. See also the discussion of change in the structure of the labour force in chapter IX, section D.

<sup>11</sup> Clark, *The Conditions of Economic Progress* (1957); Kuznets, "Quantitative aspects of the economic growth of nations. II ..." (1957), his *Six Lectures on Economic Growth* (1959) and his *Modern Economic Growth* ... (1966), pp. 96-97, where he concludes that while the declining trends in the share of agricultural product and the upward trend in that of the secondary sectors was found in all countries, the changes in the shares of tertiary activities were not pronounced nor uniform. In some cases this share increased, in others it decreased, but in the majority of all of these the changes were insignificant.

<sup>12</sup> Davis, "The origin and growth of urbanization ..." (1955); and his "Internal migration and urbanization ..." (1955); Lampard, "The history of cities ..." (1955); Hauser, ed., *Urbanization in Latin America* ... (1961), pp. 36-37; Lewis, *The Theory of Economic Growth* (1963), p. 337; Kuznets, "Population redistribution, migration ..." (1953); and his "Urbanization and economic growth in Asia" (1957); Davis and Hertz Golden, "Urbanization and the development of pre-industrial areas" (1954); Davis, "The origin and growth of urbanization ..." (1955); United Nations, *Report on the World Social Situation* ... (1957).

<sup>14</sup> Weber, *Über den Standort* ... (1909); Hoyt, "Forces of urban centralization ..." (1941); Hoover, *The Location of Economic Activity* (1948), pp. 116-141; Fourastié, *Le grand espoir du XX<sup>e</sup> siècle* (1949), p. 180; Isard, "The general theory of location ..." (1949); and his "A general location principle ..." (1952); Lösch, *The Economics of Location* (1954); Hoselitz, "The role of cities in the economic growth ..." (1953); and his "Generative and parasitic cities" (1955); Lampard, "The history of cities ..." (1955); Davis, "Internal migration and urbanization ..." (1955); Hauser, ed., *Urbanization in Asia and the Far East* ... (1957), p. 73; Kuznets, "Population redistribution, migration ..." (1964); and his *Toward a Theory* ... (1965), p. 29; Guyot, *Essai d'économie urbaine* (1968), pp. 238 ff.

precisely known.<sup>15</sup> Not only is it technically possible to combine the pursuit of agriculture with urban living and that of modern industry with rural living,<sup>16</sup> but there is no assurance that the processes of urbanization and industrialization will always be balanced. As has been pointed out by a number of writers in connexion with recent trends, in many less developed countries urbanization may have occurred at a more rapid pace than that warranted by the rates of economic development and industrial progress.<sup>17</sup>

9. Structural transformation and urbanization are only two, though important, manifestations of economic growth. The latter, as previously indicated, is associated with a large number of other changes in the organization and functioning of the economy and society.<sup>18</sup> The spread of modern technology has as a necessary concomitant important changes in the character of the productive organization. The large capital requirements, beyond the means of the individual or the traditional firm, and the scale of operations, requiring new forms of management, give rise to the emergence of the corporate and public enterprise as the predominant form of productive organization. The breakdown of the traditional forms of production for the family or local market, which occurs once substantial food surpluses are produced, evolves, through the specialization of economic activities, into the industrial system of production for national or international markets. Related with all these changes and determined also by the ownership of and relationships with the means of production, are the rise of new occupational and social classes and the distribution of income among them.

10. The points of contact between population and economic growth are many, but as has been noted before, the lack of adequate and sufficiently detailed long-term series of statistics and the limited usefulness of short-term data as a basis for inferences regarding the relations between demographic factors and economic growth are among the main reasons for a much less than complete knowledge of these interrelationships.<sup>19</sup> With respect to

the economic data, the problems of reliability, conversion and comparability of national income estimates for purposes of international comparison are other important complicating factors. Long-run series of national income or product may be biased by a number of factors, such as changes in price-relationship between various product groups and in the quality of products or services, which cause overstatements or understatement of the long-term rate of economic growth. Likewise, the international comparison of income levels involves a multitude of problems as the conversion of national incomes into a common denominator by means of the official rates of exchange of currencies is another source of error.<sup>20</sup>

## B. Population and economy in the modern period

11. Economic growth conceived as a sustained, rapid increase of aggregate income or income per head is, as noted above, a relatively recent phenomenon in the history of mankind. Initiated about two centuries ago, its effective beginnings have come to be associated with the radical transformation of the economy which became known as the industrial revolution. Although often associated with the development of manufacturing, the industrial revolution encompassed much more than that. It revolutionized not only other economic activities, including agriculture, transportation, commerce and banking, but penetrated all levels of society changing decisively social institutions and patterns of behaviour. Also affected was population; the economic and social changes were accompanied by profound demographic changes. Thus the period of modern economic growth, apart from witnessing an unprecedented and sustained long-term economic growth, extensive structural transformations and massive social change, constitutes also a distinct phase in demographic history. Accompanying the industrial revolution, the new demographic trends which emerged at the time have come to be regarded in the view of many as an integral aspect of the era of modern economic growth.

12. Over-all trends in economic and population growth, however, do not reflect the diversity of these processes in historical and geographical perspective. They not only fail to take into account the varied experience of individual countries, but, moreover, do not reveal the limited spread of modern economic growth from which emerged the present division of the world into the economically more advanced and less advanced countries. The period of modern economic growth has come to be associated with large and increasing inequalities of income between the more developed and less developed countries. Likewise, the world-wide demographic evolution in the modern period conceals large differences between these groups of countries. Finally, great differences in the levels, evolution and structure of industrialization and urbanization were inevitably linked with these divergent economic

<sup>15</sup> Hoselitz, "The role of cities in the economic growth ..." (1953); Hauser, ed., *Urbanization in Asia and the Far East* ... (1957), pp. 65-66; United Nations, *Report on the World Social Situation* ... (1957), p. 123.

<sup>16</sup> Kuznets, *Toward a Theory* ... (1965), p. 97; and his "Consumption, industrialization and urbanization" (1966). See also Schnore, "The statistical measurement of urbanization ..." (1961); Higgins, "The city and economic development" (1967).

<sup>17</sup> Davis and Hertz Golden, "Urbanization and the development of pre-industrial areas" (1954); Davis, "Internal migration and urbanization ..." (1955); Hoselitz, "Generative and parasitic cities" (1955); and his "Urbanization and economic growth in Asia" (1957); United Nations, *Report on the World Social Situation* ... (1957), p. 124; Hauser, ed., *Urbanization in Asia and the Far East* ... (1957); ———, *Urbanization in Latin America* (1961), p. 37; International Labour Office, *Why Labour Leaves the Land* ... (1966); George, *Géographie de la population* (1967), pp. 81-82; Guyot, *Essai d'économie urbaine* (1968), pp. 248-251. See also Sovani, "The analysis of over-urbanization" (1964).

<sup>18</sup> Kuznets, "Population, income and capital" (1955) and his *Toward a Theory* ... (1965), pp. 23, 98-101; Deane, *The First Industrial Revolution* (1965), p. 1.

<sup>19</sup> An additional complication is that since for the present chapter use has been made of data from different sources, some of the statistical information presented is not comparable with that shown in another place or originating from a different source. No attempt has been made to ensure comparability in this respect.

<sup>20</sup> For a discussion of the issues involved and attempts to prepare comparable estimates of some of the basic economic variables, including the use of purchasing power equivalents, see Clark, "Internationaler Vergleich der Volkseinkommen" (1938) and his *The Conditions of Economic Progress* (1957); Gilbert and Kravis, *An International Comparison of National Products* ... (1954); Gilbert and associates, *Comparative National Products* ... (1958).

and demographic trends. Even though at the beginning of the modern period the economic, demographic and other conditions in the presently more developed and less developed countries had already diverged substantially, the two centuries since then have seen a widening of this gap.

13. The purpose of this section is to present a broad sketch and interpretation of the major economic and demographic trends and structural changes which emerged in the period of modern economic growth. The first part deals with general aspects of the process of economic growth and demographic change as well as their general interrelations during this period with special reference to the divergencies between the more developed and the less developed countries. The second part concerns mainly the structural changes which have been associated with these processes.

# 1. ECONOMIC GROWTH AND DEMOGRAPHIC CHANGE IN THE PERIOD OF MODERN ECONOMIC GROWTH

## (a) *Growth of income*

14. As noted above, the period of modern economic growth is generally assumed to have started some two centuries ago with the industrial revolution in England.<sup>21</sup> Reliable over-all economic indicators which go as far back as several centuries are scarce and inferences on the extent, spread and rate of economic growth, especially as far as the early phases of development are concerned, are mostly based on circumstantial or indirect evidence or partial information available for selected countries only. Nevertheless, several characteristics of economic development during this period are sufficiently well-established to permit some generalizations. First, economic growth and development during the last two centuries have been so rapid that they constitute, without doubt, a distinct era in man's history. Secondly, even so, the spread of this process of economic growth has been very uneven and has been such as to create at present a large and widening gap in levels of income and living between those countries which benefited from the process of economic growth and those which did not.

15. Various arguments have been used to demonstrate rapid economic growth during the modern period. For example, indirect evidence that during this period production has expanded at rates not witnessed before is thought to be provided by a general comparison of living conditions as they are known to have existed prior to the beginning of this period and as they are at present in the more developed countries. Another indirect argument is that since there is little doubt that population growth accelerated during the modern period and *per capita* income did not decline, total production of goods and services must have increased at a substantially higher rate than before.<sup>22</sup>

<sup>21</sup> Some difference of opinion, however, still persists as to the period when the industrial revolution in England took place. See section D below.

<sup>22</sup> Kuznets, *Modern Economic Growth* ... (1966), pp. 63, 68-69. Nevertheless, the view is often found that in the early stages of modern economic growth the living conditions of large segments of the labouring classes did not improve, but deteriorated, despite a more rapid rate of over-all economic growth.

In fact, direct and circumstantial evidence, it has been asserted, suggests that *per capita* income has been rising during the modern period. Incomplete, but persuasive data, it is noted, show that since the beginning of the modern period income has increased many times in Europe and overseas areas of European settlement and that levels of living in the rest of the world have not declined significantly. Consequently *per capita* income for the world as a whole must have risen. The evidence on growth in *per capita* income in the last fifty years, which is more direct, is held to confirm this reasoning.<sup>23</sup> Some admittedly rough and tentative estimates of the growth of world income have been made. One of these suggests that in 1850 the world's total real income was between a fifth and a quarter of what it was around 1940.<sup>24</sup> A different set of estimates implies that in 1913 the world's income was only 40 per cent of what it amounted to in 1953.<sup>25</sup> Apart from these general arguments and rough estimates, inferences on long-term economic growth, especially for individual countries, have been based on partial information. Long-term series on the production and the development of manufacturing of certain goods or product categories which played a crucial role in the early phases of modern economic growth, such as textiles, iron, coal and energy production, as well as statistics on foreign trade, have been used for such purpose.<sup>26</sup>

16. A number of economists, among them especially Clark and Kuznets,<sup>27</sup> have attempted to estimate and bring together data on long-term trends in the growth of income or product for as many countries as possible.

<sup>23</sup> Hagen, "World economic trends ..." (1958).

<sup>24</sup> Robinson, "The changing structure of the British economy" (1954). See also Meier and Baldwin, *Economic Development* ... (1957), p. 247.

<sup>25</sup> Zimmerman, *Arme und reiche Länder* (1963), pp. 46-47, tables 2.4 and 2.6, p. 30.

<sup>26</sup> See, for instance, Mantoux, *The Industrial Revolution in the Eighteenth Century* ... (1928, 1961 ed.); Ashton, *An Economic History of England* ... (1955); Hoffman, *British Industry* ... (1955); Deane, *The First Industrial Revolution* (1965). For other studies where such indicators are used see Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 216-221; Parrish, "Iron and steel ..." (1956); d'Hérrouville, "Réflexions sur la croissance" (1958); Cipolla, *The Economic History of World Population* (1962), pp. 47 ff.; Gill, *Economic Development* ... (1964), pp. 49-51. In the socialist countries the volume and indices of certain important products are often used as indicators of economic growth. For studies relying to a considerable extent on statistics of international trade for the analysis of economic growth, see, for instance, Deane and Cole, *British Economic Growth* ... (1962) and Cole and Deane, "The growth of national incomes" (1965).

<sup>27</sup> Clark, *The Conditions of Economic Progress* (1957), chaps. 2 and 3, compiled data on national product for a large number of countries; Kuznets, "Quantitative aspects of the economic growth of nations. I. ..." (1956); his *Aspectos cuantitativos del desarrollo económico* (1959); his *Modern Economic Growth* ... (1966) and his *Economic Growth of Nations* ... (1971). Other comparative studies dealing with long-term economic growth in mostly developed countries include Maddison, *Economic Growth in the West* ... (1964), chap. 1; Bairoch, *Révolution industrielle et sous-développement* (1963); Kindleberger, *Economic Growth in France and Britain* ... (1969). Some estimates of "national income" were made at an early date. Best-known among these is Gregory King's estimate for England. See Barnett, ed., *Two Tracts by Gregory King* (1936). For a reclassification of King's estimates in modern form, see Deane, "The implications of early national income ..." (1955) and Deane and Cole, *British Economic Growth* ... (1966), pp. 155-156.

Kuznets found that in fourteen mostly developed countries for which data on income for at least five decades were available, *per capita* income had increased from between somewhat less than 10 to over 20 per cent per decade.<sup>28</sup> He confirmed these findings in later studies with data extending over a longer period and noted that, with only few exceptions, the decade rates of growth of *per capita* income were well over 10 per cent, and in some cases considerably more than 20 per cent.<sup>29</sup> Long-term estimates of *per capita* income since the beginning of modern economic growth in each country suggested per decade growth rates between 14 and 23 per cent for the majority of the fourteen countries considered, with no rates lower than 10 per cent and some as high as 30 per cent per decade.<sup>30</sup> Kuznets stressed not only the rapid rate of economic growth which these data revealed, but also that growth rates in the modern period were much higher than in pre-modern times. The evidence in this respect was direct where income estimates went as far back as pre-modern times.<sup>31</sup> Indirect proof was obtained by projecting backward, into the period before modern economic growth began, the rates of increase of *per capita* income typical for the modern period. The level of income would have declined to an impossibly low one, according to this calculation, about one century before the beginning of modern economic growth. The increase of *per capita* income in the modern period, Kuznets concluded, was thus much higher than in the period prior to that and higher than it could have been over many centuries before.<sup>32</sup>

17. Practically all data on economic performance and inferences concerning the potential for economic growth in the modern period, cited so far, are based on the experience of the presently developed countries. Comparable long-term data for developing countries are virtually lacking,<sup>33</sup> but, in general, it may be assumed that economic growth in these countries was slow or stagnant for the greater part of the modern period. Several arguments in support of such a hypothesis were advanced by Kuznets. As evidence, he cited the present low levels of *per capita* income in most developing countries as well as the fact that where economic growth had appeared possible in the past, population growth had also accelerated, increasing total output but keeping *per capita* income at low levels. The available estimates of long-term trends in *per capita* income in developing countries tended to confirm these conclusions.<sup>34</sup> In general terms, Hagen estimated that among the less developed regions only Latin America experienced a distinct increase in *per capita*

income in the first half of this century, while *per capita* income may have remained about the same in Asia, and little is known about its level and evolution in Africa.<sup>35</sup> Zimmerman's rough and tentative estimates of *per capita* income for 1913 and 1953 show only small increases in most parts of Asia, but more substantial gains in Latin America.<sup>36</sup> On the basis of similar data for the first half of this century the growth of the domestic gross product of Latin America and Asia, excluding China and the Middle East, was estimated to have fluctuated around 2 per cent annually. However, as a result of an increasing rate of population growth, *per capita* increases declined from 1.2 per cent annually in 1900-1913, to 0.9 per cent in 1913-1929 and to 0.6 per cent in 1929-1953.<sup>37</sup>

18. Statistical data, however, are not needed to confirm that modern economic growth was not only unique, but also had only a limited spread. England being the first country to experience an industrial revolution, its example was followed at different times by the countries of western, northern and central Europe, the overseas areas of predominantly European settlement, the USSR, the countries of eastern and southern Europe and Japan. The large majority of the nations of Africa, Asia and Latin America did not share in this process. Both direct and indirect evidence suggests that incomes in the countries of early development prior to the modern period were already considerably higher than in the presently developing countries.<sup>38</sup> These differences, it is generally agreed, have increased in the course of the period of modern economic growth.<sup>39</sup> Evidence of an indirect nature on the growing differentials in income has been presented especially by Kuznets, who showed that growth rates of *per capita* income as rapid as those experienced by the more developed countries could not have occurred in the less developed ones taking into account their present level of income.<sup>40</sup> Spengler speculated that product per man-hour in the most advanced countries was perhaps five times that of the least advanced before 1800, while this multiple may exceed forty at present.<sup>41</sup> Cairncross thought that in the richer countries

<sup>35</sup> Hagen, "World economic trends ..." (1958).

<sup>36</sup> Zimmerman, *Arme und reiche Länder* (1963), pp. 46-47, tables 2.4 to 2.6, estimated that *per capita* income in prices of 1952-1954 increased in Latin America from \$170 in 1913 to \$260 in 1953. For the Far Eastern countries the corresponding estimates were \$90 in 1913 and \$110 in 1953. *Per capita* income in South-East Asia was estimated to have remained virtually the same with \$64 in 1913 and \$65 in 1953. China's *per capita* income was thought to be about \$50 throughout the first half of this century.

<sup>40</sup> Kuznets, "Population, income and capital" (1955); his "Quantitative aspects of the economic growth of nations. I. ..." (1956); his *Modern Economic Growth* ... (1966), pp. 392-393, and his *Economic Growth of Nations* ... (1971), p. 27.

<sup>41</sup> Spengler, "Demographic patterns" (1954).

real income may have risen fivefold within the last century, whereas in many less developed countries it may have barely increased.<sup>42</sup> According to tentative estimates by Robinson, Africa, Asia and Latin America accounted for over 45 per cent of the world's real income in 1850, but their share had declined to less than 30 per cent in the 1930s.<sup>43</sup>

19. While thus for the greater part of the period of modern economic growth the less developed countries experienced on the whole little or no economic growth, the evolution over the last few decades shows a different tendency. In the large majority of countries, including both developing and developed, the rate of economic expansion was considerably higher than it was during most of the rest of the century. It is also generally recognized that, with some exceptions, economic growth in most developed countries has been rapid over the last two decades. But rapid growth of product and income was not limited to the countries which traditionally had expanded faster; most developing countries experienced over the last two decades rates of increase of total and, to a lesser extent, *per capita* income which were, on the average and compared with earlier periods, very high. Even though the interpretation of the reasons for such acceleration and the opinions whether the post-war period represents a new phase in economic growth differ, the fact remains that during these decades production increased at comparatively high rates in most countries.<sup>44</sup>

#### (b) *Population and economic growth: their interrelations*

20. The problem of the possible interrelations between economic and population growth is generally recognized to be a complex one. As has been noted before, not only are sufficient data lacking, but the indirect nature of the relationships implies in fact that both the direction and extent of the association between the two may vary over time and space. The concentration of broad trends in the growth of population in the major regions with the general trends in economic growth sketched in the preceding subsections suggests that while population and economic growth in the modern period have not been independent of each other, no invariable and systematic relation between the two exists.

21. Compared with the knowledge of economic trends during the modern period, more, albeit incomplete, data on population growth are available. Historical population estimates for the world, regions and some individual countries have been discussed in a preceding chapter.<sup>45</sup> Despite the limitations of the data, the findings in that chapter provide ample evidence of the emergence of new demographic patterns over the last two centuries or so. In a broad historical context and in relation to the process of modern economic growth, two distinctive features of population trends during this period stand out: first, a

very large increase of population, in both absolute and relative terms, compared with earlier periods in man's history and, secondly, a rate of increase in recent decades faster than ever before.<sup>46</sup>

22. Conjectures and estimates of population since the beginning of the Christian era attest to the large increase of population in the modern period in comparison with earlier history. At the beginning of the Christian era the world's population may have been of the order of 300 million; it probably reached some 500 million in 1650 and around 800 million in 1750. Between the approximate beginnings of the period of modern economic growth and 1900, the population of the earth increased to 1,650 million and reached close to 3,300 million by 1965.<sup>47</sup> The less than threefold increase from the beginning of the Christian era until 1750 implied, as Durand noted, a doubling of the population in as much as over a thousand years. By comparison, between 1750 and 1965, a little over two centuries, the world's population quadrupled.<sup>48</sup>

23. The estimates cited also confirm an acceleration of population growth during the modern period. It has been observed that, while it took about one and a half centuries after 1750 for the population to double, in less than two thirds of a century, between 1900 and 1965, a doubling also took place.<sup>49</sup> Although it is sometimes assumed that a steady and gradual acceleration of population growth has taken place over approximately the last two centuries,<sup>50</sup> more detailed estimates suggest that this speeding-up of population growth was a relatively recent phenomenon.<sup>51</sup> Average rates of growth for half centuries between 1750 and 1900, based on the various estimates available, reveal at most a slight acceleration in growth during this period.<sup>52</sup> More rapid population growth started to manifest itself only in the present century: between 1900 and 1950 world population is estimated to have increased at an average annual rate of 0.8 per cent.<sup>53</sup> The most startling acceleration, it is generally

<sup>46</sup> Cipolla, *The Economic History of World Population* (1962), pp. 99-101; Kuznets, *Modern Economic Growth* ... (1966), p. 37.

<sup>47</sup> See chapter II, table II.1. For years up to 1900 this table presents ranges of estimated population size of which the figures cited here are approximate mid-points.

<sup>48</sup> Durand, "A long-range view ..." (1967), and his "The modern expansion ..." (1967).

<sup>49</sup> *Ibid.*

<sup>50</sup> See, for instance, Davis, "The world demographic transition" (1945); Borrie, *Population Trends and Policies* ... (1948), pp. 1-2; Kuznets, *Toward a Theory* ... (1965), pp. 10-11.

<sup>51</sup> See chapter II, section E. Also Durand, "The modern expansion ..." (1967); Grauman, "Population growth" (1968).

<sup>52</sup> See table XIV.1. Carr-Saunders' estimates imply average annual rates of growth of 0.4 per cent between 1750 and 1800; 0.5 per cent from 1800 to 1850 and 0.6 per cent from 1850 to 1900. The estimates by Willcox signify average annual growth rates of 0.6, 0.3 and 0.7 per cent, respectively. Durand estimated the average annual growth rate to have been 0.4 per cent between 1750 and 1800, and 0.5 per cent from 1800 to 1850 and from 1850 to 1900.

<sup>53</sup> Durand, "The modern expansion ..." (1967), stressing particularly the contrast between the relatively stable growth until the end of the nineteenth century and the acceleration since then, considered the periods before and after 1900 as distinct stages in modern population growth. See also Grauman, "Population growth" (1968).

SOURCES: 1650-1900: Carr-Saunders, *World Population* ... (1936), p. 42; Willcox, *Studies in American Demography* (1940), p. 45; 1750-1900 also Durand, "The modern expansion ..." (1967); 1900-1920: Bour-

geois-Pichat, *Population Growth and Development* (1966), table 6, p. 16; 1920-1960: United Nations, *World Population Prospects* ... (1966).

<sup>a</sup> Lowest and highest estimates from the sources cited.

recognized, was that which occurred in the post-war period, as the average annual growth rate rose to 1.8 per cent between 1950 and 1960 (see table XIV.1). These long-term trends during the modern period have led to the view that since its beginnings population growth has passed through two stages: a period of relatively modest growth, which is supposed to have lasted until the first half of the twentieth century, and a phase of very rapid growth since the Second World War.<sup>54</sup>

24. In view of both the quantitative and qualitative limitations of data, inferences on the interrelations between population and economic growth during the modern period are necessarily tentative. The available data and indirect information appear to bear out the existence of an over-all positive association between the two during the period. Kuznets pointed out that economic growth in the modern period meant not only sustained and marked increases in *per capita* product, but also in population. This combination of high rates of population growth and of *per capita* income and, by implication, very large increases in total product was, in his view, a distinctive characteristic of modern economic growth.<sup>55</sup> Hagen noted also that since the industrial revolution high and increasing rates of growth of population have been accompanied by an even more rapid growth of income.<sup>56</sup> Although it has received less attention, the recent upsurge of world economic and population growth during the post-war period would appear to confirm the existence of an over-all positive association between the two.

25. Broad generalizations of this nature, however, have little meaning failing as they do to distinguish variations in levels and patterns of growth over time and for different regions and countries. Thus it has been noted, for instance, that population growth apparently started to accelerate before the period of modern economic growth. The very rough estimates for earlier centuries indicate that up to 1650 the rate of population growth may have been less than 0.1 per cent—the average rate from the beginning of

the Christian era to 1650 being 0.07 per cent. From 1650 to 1750 and before the beginning of modern economic growth the growth rate is estimated to have increased significantly to between 0.3 and 0.4 per cent.<sup>57</sup> Growth patterns for different regions, while providing in some instances confirmation of a positive association between population and economic growth, also show that such an association is not universally valid or invariable and may, in fact, turn into a negative association.

26. Population trends during the modern period were an uneven process—as was economic growth—and affected different regions and countries in a different manner at different times. A large number of writers, in interpreting population growth trends during the modern period, have noted that, for the greater part of this era, population growth, on the whole, was higher in the area of European settlement.<sup>58</sup> The faster growth of population, which has come to be associated with modern economic growth, is often assumed to have started first in Europe where modern economic growth originated.<sup>59</sup> Subse-

<sup>57</sup> See chapter II, table II.1. Also Davis, "The world demographic transition" (1945); Thompson and Lewis, *Population Problems* (1965), p. 401. Others, however, have questioned the reliability of these and any estimates prior to the nineteenth century. See, for instance, Kuczynski, "Population" (1948). Durand, "The modern expansion ..." (1967), also expressed doubts about the accuracy of the estimates for 1650, but accepted that accelerated growth began probably before 1750 in some parts of Europe, Russia and America and possibly before 1700 in China.

<sup>58</sup> See, among others, Carr-Saunders, *World Population* ... (1937), pp. 42-45; Davis, "The world demographic transition" (1945); Thompson, *Plenty of People* (1948), pp. 7-8; Woytinsky and Woytinsky, *World Population and Production* ... (1953), p. 36; Cipolla, *The Economic History of World Population* (1962), pp. 101-104; Köllmann, *Bevölkerung und Raum* ... (1965), p. 1; Kuznets, *Modern Economic Growth* ... (1966), pp. 36-40.

<sup>59</sup> Carr-Saunders, *World Population* ... (1937); Cipolla, *The Economic History of World Population* (1962), pp. 101-104; Hauser, "World population: retrospect and prospect" (1971). This view, however, has been contested. For instance, Willcox, "Increase in the population of the earth ..." (1931), speculated that the century prior to 1750 was characterized by a relatively faster growth of the population of Asia. Reinhard and Armengaud, *Histoire générale de la population mondiale* (1961) are of the opinion that the population of the greatest part of Europe was stagnant from the end of the sixteenth to the middle of the eighteenth century. Durand, "The modern expansion ..." (1967), noted in more general terms that although it appears to be taken for granted that European countries took the lead in the modern population expansion, over the past two centuries Europe did not stand out among the major areas for its high population growth. He recognized, however, that the expansion of European peoples took place partly in areas of overseas settlement.

<sup>54</sup> See chapter II, section E. Also Cipolla, *The Economic History of World Population* (1962), p. 104; Thompson and Lewis, *Population Problems* (1965), p. 432; Macura, "The long-range outlook ..." (1968); Hauser, "World population: retrospect and prospect" (1971).

<sup>55</sup> Kuznets, *Modern Economic Growth* ... (1966), pp. 19-20, 63. See also his *Toward a Theory* ... (1965), p. 6, and his "Population and economic growth" (1967).

<sup>56</sup> Hagen, "World economic trends ..." (1958).

quently, even more rapid increases, partly as a result of immigration, were found in overseas areas of European settlement, especially North America. Carr-Saunders observed that between 1650 and the 1930s the European peoples multiplied some seven times—from about 100 to 720 million—while the rest of the world's population increased only three times.<sup>60</sup> Others have noted that the population of European stock multiplied more than five times between 1750 and 1950—from an estimated 140 to 150 million in the former year to 780 to 800 million in the latter—whereas the population of the rest of the world was estimated in 1950 to have been less than three times as large as it was in 1750.<sup>61</sup> According to another calculation, the population of the European countries of early development—Belgium, France, Germany, the Netherlands, Scandinavia and the United Kingdom—combined with that of Northern America and Oceania multiplied more than six times, from about 60 million in 1750 to more than 370 million in 1950. In the same period the rest of the world's population multiplied only slightly more than three times.<sup>62</sup>

27. Estimated growth rates for different time intervals in general confirm a more rapid increase of population in the predominantly more developed areas of European settlement than in other parts of the world between 1750 and the early decades of the twentieth century (table XIV.1). The estimates, which go as far back as 1650, indicate that growth rates in the two major regions did not differ ascertainably before 1750, and also that during the latter half of the eighteenth century population growth in the areas of European settlement was only slightly higher than that of the combined population of Africa, Asia and Latin America. As various writers have noted, a significant gap in growth rates emerged only in the first half of the nineteenth century and increased during the latter half of it.<sup>63</sup> The total population of the areas of European settlement increased on the average between 0.7 and 0.8 per cent annually from 1800 to 1850 and between 1.0 to 1.1 per cent from 1850 to 1900. Growth rates of the combined population of Africa, Asia and Latin America were estimated to be of the order of 0.4 to 0.5 per cent during the first half and of 0.2 to 0.4 per cent in the course of the second half of the nineteenth century (see again table XIV.1).

<sup>60</sup> Carr-Saunders, *World Population ...* (1937), pp. 42-45. See also Davis, "The world demographic transition" (1945); Landis and Hatt, *Population Problems ...* (1954), pp. 21-22; Borrie, *The Growth and Control ...* (1970), p. 7.

<sup>61</sup> Woytinsky and Woytinsky, *World Population and Production ...* (1953), p. 36; Köllmann, *Bevölkerung und Raum ...* (1965), pp. 1-2. The estimates are not always clear as to which population and area they refer to. The area of European settlement is usually defined as consisting of Europe, North America, Oceania and the USSR and, in a number of cases, Middle and South America. Durand, "The modern expansion ..." (1967), presents estimates of population growth for the area of European settlement including and excluding Middle and South America. In the former case the corresponding population in 1950 is 4.9 times that in 1750, in the latter case the multiplication factor is 4.4.

<sup>62</sup> Kuznets, *Modern Economic Growth ...* (1966), pp. 36-40.

<sup>63</sup> Bourgeois-Pichat, *Population Growth and Development* (1966), p. 13; Thompson and Lewis, *Population Problems* (1965), pp. 413-414, 416; Durand, "The modern expansion ..." (1967).

28. The pattern of a more rapid growth of the population in the areas of European settlement, as compared with the rest of the world, which had emerged in the course of the nineteenth century underwent a complete change in the twentieth century. Comparisons of population growth trends for the first half of the twentieth century are hampered by fluctuations in growth rates—especially in the predominantly more developed countries of the areas of European settlement—caused by periods of war, economic crisis and subsequent recovery. But on the basis of data for the decades which can be considered as more or less normal, it appears that population growth in these areas has become stabilized since the end of the nineteenth century.<sup>64</sup> In the meantime the population in the rest of the world started to grow faster and in the decades 1911-1920 and 1921-1930 rates of increase in both major segments were about the same (table XIV.1). Since then the combined population of Africa, Asia and Latin America increased at a considerably higher rate than that of the areas of predominantly European settlement. During the 1930s and 1940s this differential was mainly due to the exceptionally low rates of growth of the latter.<sup>65</sup> Since the 1950s, however, when population growth in the areas of European settlement had returned to a more normal level, the difference has been the result of a considerable acceleration of the rate at which the population of Africa, Asia and Latin America combined increased. Between 1950 and 1960 their population increased at an unprecedented average annual rate of 2 per cent as compared with about 1.3 per cent in the areas of European settlement.

29. Since the areas of European settlement coincide to a large extent with the presently more developed regions,<sup>66</sup> the reversal of the traditional situation with respect to differentials in population growth in the major areas is also found in the estimates for more developed and less developed regions. Estimated decennial growth rates since 1920, prepared by the United Nations, show that in the 1920s population increased at a faster rate in the more developed areas, but from 1930 on the opposite was true.<sup>67</sup> The most striking development occurred in the 1950s when population growth in the less developed regions accelerated to an unprecedented level with an

<sup>64</sup> Durand, "The modern expansion ..." (1967); Bourgeois-Pichat, *Population Growth and Development* (1966), pp. 14-15; Hauser, "World population: retrospect and prospect" (1971). Several writers have argued, however, that the growth of population of European stock reached a peak in the latter half of the nineteenth century. See, for instance, Reinhard and Armengaud, *Histoire générale de la population mondiale* (1961), pp. 229-230; Borrie, *The Growth and Control ...* (1970), p. 7.

<sup>65</sup> See Macura, "The long-range outlook ..." (1968); Thompson and Lewis, *Population Problems* (1965), p. 417.

<sup>66</sup> The correspondence between areas of European settlement and economically more developed regions is not complete. If Latin America is excluded from the former, such countries as Argentina and Uruguay and possibly some others, which might be considered as developed, would be excluded. In the opposite case the whole of less developed Latin America would be included. In addition, the area of European settlement excludes Japan, which forms part of the group of developed countries. See on this point also Macura, "The long-range outlook ..." (1968).

<sup>67</sup> United Nations, *World Population Prospects ...* (1966), p. 22; El-Badry, "Population projections for the world ..." (1967); Vávra, "Projection of world population ..." (1967).

increase of 23 per cent for the decade, compared to 14 per cent in the more developed regions (see section C below and table XIV.5).

30. To the extent that generalizations on population trends during the modern period are possible, the data for different regions convey the impression that, on the whole, population increased more rapidly in those areas where economic progress was also more rapid. Since the beginning of the period, the group of more developed countries has achieved enormous increases in total product, both in absolute and relative terms as well as in comparison with earlier periods,<sup>68</sup> has seen its population increase by some five times and has made gains in *per capita* income which ranged from 10 to well over 20 per cent per decade.<sup>69</sup> In contrast, during the greater part of modern history population in the less developed countries increased relatively slowly, having grown by an estimated 200 per cent between 1750 and 1950; even so, as the mostly indirect evidence discussed before suggests, *per capita* income in many of these countries increased only insignificantly or not at all as the growth of total output barely kept pace with that of population. In general, population and economic growth trends, at least until a few decades ago, suggested the existence of a positive association between population and economic growth for the broad groups of more developed and less developed countries.<sup>70</sup> To the extent that population and *per capita* income growth in the rest of the world remained below the levels characteristic for the presently developed countries, higher rates of growth and higher levels of *per capita* income in the latter were accompanied by higher rates of increases of population. Slower population growth in the less developed regions was associated with low, if any, increases in *per capita* income and levels of development.

31. Even though economic growth in the modern period has been accompanied by rapid growth of population, in general, and, until recently, a positive association also prevailed with respect to more developed and less developed regions and countries, data for the two groups of countries in the more recent period and for individual

countries imply either a negative association or the absence of a systematic relationship.

32. The higher rate of population growth since the approximate beginnings of the modern period, which had its main impact in the more developed countries, was followed, as noted before, by an even more marked acceleration in the post-war period, giving rise to an unprecedented population growth in the economically less developed countries. When economic and population growth slowed down in the more developed countries in the 1930s, while population growth in the less developed ones continued an upward trend, the traditional positive association between population and economic growth was already considerably weakened. It reversed itself in the post-war period when population growth in the developing countries rose to a level nearly double that of the more developed countries and, despite a much faster increase in total product than in the past, growth rates in *per capita* income in the developing countries remained below those of the more developed countries.<sup>71</sup> Thus, the long-term positive relation between population and economic growth and development, which had prevailed until the 1930s, no longer held and an inverse relation emerged in recent decades.<sup>72</sup>

33. Long-term data for individual countries also do not substantiate the assumption of a systematic association between population and economic growth. A number of writers have commented on the fact that in the past countries with high rates of population growth did not necessarily show high rates of increases in *per capita* income or vice versa. Nor was there any evidence of an inverse association, in the sense that low rates of population growth would be accompanied by high growth rates of *per capita* product, or vice versa. Considered individually, it is asserted, there were countries characterized by both high growth of population and *per capita* product (United States, Canada); high population growth and low *per capita* income growth (the Netherlands); low population growth, but high *per capita* income growth (Sweden) and low rates of increase in both population and income (Belgium, France).<sup>73</sup>

34. Historical population estimates raise some additional questions concerning the interrelationship with economic growth. Estimates for periods prior to 1750 imply, as noted above, that in a number of countries higher rates of population growth may have manifested themselves well before modern economic growth began. Although, as has also been pointed out, the timing of

<sup>68</sup> Kuznets, *Economic Growth of Nations* ... (1971), pp. 24-25, estimates that in the older European countries economic growth during the modern period implied increases in total product of 6 to 24 times over a century, compared with possible growth factors of 1.25 to 1.50 in the preceding centuries. Kaldor, "Characteristics of economic development" (1962) estimates that rates of growth in national production in Western Europe and Northern America since 1750 were roughly 30 to 40 times as high as that experienced over many earlier centuries.

<sup>69</sup> Kuznets, *Modern Economic Growth* ... (1966), p. 67.

<sup>70</sup> Kuznets, *Modern Economic Growth* ... (1966), pp. 36, 40; his "Population and economic growth" (1967) and his *Economic Growth of Nations* ... (1971), p. 23; Kaldor, "Characteristics of economic development" (1962). It has also been implied that at least in the case of the more developed countries, declines in the rates of *per capita* income growth, which manifested themselves in many of these countries during the first half of the present century, were accompanied by a slower growth of population. On this point see the discussion of the stagnation theory in chapter XIII. Also Kuznets, "Population, income and capital" (1955), Buchanan and Ellis, *Approaches to Economic Development* (1955), p. 215; Bairoch, *Révolution industrielle et sous-développement* (1963), p. 26.

<sup>71</sup> See section C below.

<sup>72</sup> United Nations, *World Population Prospects* ... (1966); Kuznets, *Modern Economic Growth* ... (1966), pp. 39-40; and his "Population and economic growth" (1967); Bourgeois-Pichat, *Population Growth and Development* (1966), pp. 14-15; Borrie, *The Growth and Control* ... (1970), p. 9. See also Durand, "The modern expansion ..." (1967) who considered, however, the former positive relationship between population growth and economic development ambiguous. For a more detailed discussion of recent trends, see section C below.

<sup>73</sup> Kuznets, "Population, income and capital" (1955); his "Demographic aspects of economic growth ..." (1966) and his *Economic Growth of Nations* ... (1971), pp. 22-23; Easterlin, "Effects of population growth ..." (1967); Robinson, "Population and development" (1960).

the period of increased population growth cannot be firmly established, Easterlin concluded that possibly the phase of more rapid growth came before modern economic growth began in, at least, a number of countries.<sup>74</sup> While, if true, this would indicate a lack of association, Kuznets presented arguments which would support the assumption of a negative association between population and economic growth at that time. He speculated that rapid population growth during the early phases of development of some countries may have prevented any significant increase in levels of *per capita* income. The latter became possible only when population growth stabilized or declined.<sup>75</sup>

35. A comparative study of the growth of population, total and *per capita* product by Kuznets supported most of the findings described so far. Analysing first data for some fourteen mostly developed countries which covered a period of fifty years or more up to 1950, he showed that substantial rates of population growth tended to be accompanied by high rates of growth of total product and that, conversely, low rates of population growth meant modest rates of growth also of total income. A positive, significant association existed, he found, between growth of population and growth of total product. The association persisted even if the areas of European overseas settlement, to which the association could be in part attributed, were excluded. Further analysis of the data suggested, however, that the role of population growth in the increase of total product was limited. Finding a positive association also between the rates of growth of total and *per capita* product implied, Kuznets noted, that different rates of population growth were not the predominant factor in the growth of total product. The results of his analysis with respect to the interrelation between population and *per capita* income growth were equally inconclusive. The rank correlation coefficient between the rates of growth of population and *per capita* product was found to be positive, thus suggesting that countries with more rapid population growth also had a more rapid growth of *per capita* income, but the value of the coefficient was not significant.<sup>76</sup>

36. Although long-term data were available only for predominantly more developed countries, Kuznets extended his analysis to speculate what influence the inclusion of the less developed countries would have on these associations. Assuming that in these countries population was regulated by the Malthusian mechanism, in the sense that its growth was held back by positive checks and that where opportunities for economic expansion were created the response would be a higher population growth, he concluded that the association between the rates of growth of population and total product would be likely to remain positive and significant. He thought also that with the inclusion of the less developed countries a significant positive correlation between the growth of population and

*per capita* income would emerge for the period considered. The inclusion of the less developed countries, he argued, would mean the addition of cases with low population growth, due to economic stagnation, and low rates of growth of *per capita* income, thus strengthening the positive, but not significant, correlation found in the case of the more developed countries.<sup>77</sup> This view was supported by Easterlin, who noted that if, for the pre-war period, less developed countries were considered together with the more developed ones included in Kuznets's analysis, higher *per capita* income growth rates would tend to be associated with higher population growth rates.<sup>78</sup>

37. These findings may to some extent be considered representative of the nature of the interrelations between economic and population growth during the modern period. They imply that population and economic growth may vary in a similar manner, in general, despite the lack of any consistent relationship between the two where individual countries are concerned. The absence of the latter means that it is also possible, as has occurred in recent decades, that a positive association, such as that which characterized global and regional trends during a large part of the modern period, may reverse itself into a negative one.

38. The lack of a systematic and uniformly valid relationship between growth of population and income per head during the modern period has been more or less generally accepted. According to Robinson, it is impossible to draw from history any generalizations about such a relationship nor to draw any conclusion whether economic growth stimulates that of population or whether the growth of population stimulates the growth of wealth.<sup>79</sup> Kuznets observed, more specifically, that while modern economic growth implied a rapid increase in *per capita* income as well as population, this did not mean that population growth was a necessary condition for the former. The positive association which existed for the greater part of the period where broad groups of countries were concerned was a loose one, as exemplified by the experience of individual countries, where a diversity of relations between low and high rates of increase of population and *per capita* income is found in both more developed and less developed countries. For the range of population growth rates found in the past, there was and is, he concluded, no invariant and significant direct effect of population growth on the rate of increase of *per capita* product.<sup>80</sup>

39. This is not to imply, it has been noted, that the level of population growth is not an important factor; to the contrary, the significance of population growth for economic growth is generally recognized.<sup>81</sup> It does mean, however, that under different conditions and in different

stages, population growth may have different consequences and may be differently affected, even to the extent that these effects and influences may be in opposite directions. The mechanism through which population changes, its determining factors and the magnitude of the change, on the one hand, and the economic, social and institutional conditions under which the change occurs, on the other, determine what its effects will be. These conditions having varied greatly over time and space, the rise in numbers thus may affect and be related to growth in income in a number of ways from which no single and well-defined pattern of interrelationship emerges.<sup>82</sup> Simple comparisons between population and *per capita* income, failing to take into account variations in growth-determining factors, it is asserted, are an over-simplification. Even so, they tend to show that the implications of population growth are not so important as to dominate other determinants of growth in general, but, according to this argument, they also suggest that, where stark contrasts in both economic, social and demographic conditions exist, the associations between population and economic growth become more clearly defined.<sup>83</sup>

(c) *Fertility, mortality, the demographic transition and modern economic growth*

40. The new trends in population growth which emerged during the modern period were evidently the reflection of changes in its two main components, fertility and mortality. Their evolution in the European countries of early development over the last centuries not only confirmed such changes but, in addition, suggested certain regularities in fertility and mortality trends which led to the hypothesis that in the course of its economic and demographic development each population undergoes a demographic transition. The theory of the demographic transition assumes, as discussed in an earlier chapter,<sup>84</sup> that each population passes through various stages of growth under different régimes of fertility and mortality. More specifically, the transition involves the evolution from a régime of high birth and death rates and low population growth to one of low birth and death rates and low growth of population. In between there is a phase of rapid growth when a "demographic gap" emerges, since mortality declines first and it is followed only with a time-lag by the onset of a fall in fertility. Although the hypothesis of such a process of evolutionary demographic change and of the three or more stages in which it occurs appear to have a more or less general validity, the transition theory has proved to be more useful as a broad scheme for explaining demographic change than as a tool for more detailed analysis. Historical and contemporary trends have shown that the transition itself and its pattern, sequence and timing may vary greatly from country to country and over time.<sup>85</sup>

<sup>82</sup> Kuznets, "Quantitative aspects of the economic growth of nations. I. . . ." (1956); his "Demographic aspects of economic growth . . ." (1966).

<sup>83</sup> Kuznets, "Demographic aspects of economic growth . . ." (1966); Easterlin, "Effects of population growth . . ." (1967).

<sup>84</sup> See chapter III, section H.

<sup>85</sup> For instance, no uniformity has been found to exist with respect to the speed of mortality or fertility decline, the duration

41. The assessment of past trends in fertility and mortality is greatly hampered by the lack of statistical data.<sup>86</sup> This is especially true for earlier periods, but even so there is little doubt that the slow increase of population during the many centuries preceding the modern period was a consequence of high levels of both fertility and mortality. Speculations by different writers as to what levels of birth, death and growth rates could be considered typical for these primitive or pre-industrial societies are generally in accord, as far as the main traits are concerned. The "normal" birth and death rates of such a society—associated with marriage at an early age, a low incidence of birth control and conditions under which no effective control over mortality existed—are thought to have fluctuated from about 35 to 50 per thousand and from 35 to 40 per thousand, respectively. These rates, it is inferred, suggest "natural" growth rates of the order of 1 per cent. In actuality, average rates of growth were much lower than that, as recurrent crises, caused by epidemics, famines and wars, would cause high peaks in mortality. During such times, it is asserted, death rates could surpass birth rates by a considerable margin and, moreover, the birth rates themselves might be negatively affected by the crises. Average crude birth and death rates, these writers conclude, may have fluctuated between approximately 35 and 45 per thousand with death rates only slightly below birth rates and average rates of growth well below the "natural" or "normal" level.<sup>87</sup>

42. The world demographic transition was set in motion when over some two centuries ago the traditional balance between fertility and mortality was disrupted. It is generally agreed that the long-term acceleration of population growth resulted from improvements in mortality conditions, while what evidence there is excludes the likelihood of a rise in fertility.<sup>88</sup> The "demographic gap" emerged when the peaks in death rates due to epidemics and famines gradually disappeared and subsequently it widened when further gains in longevity occurred as "normal" mortality came under increasing control.<sup>89</sup> Despite a sharp fall in the more developed countries, fertility did not change much on a global scale and remained on the whole high. The decline in mortality, as the predominant factor in world demographic trends during the modern period, is thought to have been conditioned to a consider-

of the various stages, the time-lag between the fall in mortality and that in fertility or the magnitude of the "demographic gap". For a more detailed discussion of the merits and limitations of the transition theory, see chapter III, section H.

able extent by the process of economic growth. Improvements in mortality conditions in the modern period have been linked to such specific factors as more stable and increased food supplies, better transportation and distribution systems or, in more general terms, to the whole complex of economic and related changes associated with modern economic growth.<sup>90</sup>

43. Although world demographic trends may suggest a process of global transition taking place, these over-all trends are the result of widely diverging evolutions in the more developed and less developed countries. The demographic transition is usually assumed to have started in European countries somewhat before or in the eighteenth century with a decline in mortality. Data for earlier periods, although scarce and incomplete, suggest the existence of high levels of mortality before that time. Estimates for different periods between the thirteenth and seventeenth century, based mainly on the experience of selected population groups, showed life expectancies at birth varying between 20 and 40 years,<sup>91</sup> figures which have been accepted as more or less representative of general mortality conditions in pre-industrial societies.<sup>92</sup> Initial improvements in these conditions were probably mainly the result of the elimination of the peaks in death rates as periodic crises became less frequent and disappeared with the advent of economic growth and progress. Increases in the life expectancies of certain more privileged groups in the population which started to manifest themselves some time thereafter have been interpreted as an indication of an incipient decline also in "normal" mortality levels. Nevertheless, large gains in longevity became evident only in the second half of the nineteenth century, and the sharpest decline in mortality in the more developed countries did not occur until the twentieth century.<sup>93</sup>

44. Fertility in a number of countries of early development, especially those in northern and western Europe, is thought to have been only moderately high already in the eighteenth century. According to historical data and estimates, crude birth rates in a number of these countries may have been well below 40 per thousand at the beginning of the modern period. However, these data also show that fertility in these countries remained high on the whole during most of the eighteenth and nineteenth centuries and that the majority of the countries of early development passed into the low-fertility category only in the late nineteenth or early twentieth century.<sup>94</sup> For the western countries as a whole, it is often asserted a fall in birth rates became apparent only in the last part of the nineteenth century.<sup>95</sup> In the broader group of

presently more developed countries, accelerated fertility decrease manifested itself only in the first decades of the present century as the rate of decline speeded up and the process itself spread to countries which until then had not experienced a significant fall in birth rates. A period of short-term fluctuations as the long-term decline came to an end was followed in more recent decades by a tendency towards stabilization and decreasing fertility differentials among the group of low-fertility countries.<sup>96</sup>

45. However, the mortality and fertility experience of individual countries within this broad group varied widely and did not necessarily conform to the general scheme outlined above. Some of the evidence in this respect suggests that the sequence of mortality and fertility decline is not well-defined. It appears, for instance, that in several countries fertility decline set in at an early date and that, in a few cases, it may have preceded the fall in mortality so that population growth, instead of accelerating, may have tended to remain more or less stable.<sup>97</sup> Other findings point to the fact that the length of the transition period may have varied considerably; in particular, it has been noted that the transition process seems to have taken a much shorter time in those countries where it began later.<sup>98</sup> Despite these and other differences in trends for individual countries, conjectures and estimates of crude birth and death rates and rates of natural increase (since 1750) for the more developed regions as a whole support, in general, the assumption of a process of transition taking place (table XIV.2). Moderate reductions in mortality since the beginning of the modern period and through most of the nineteenth century were later followed by a rapid decline in death rates, a trend which was countered, in turn, in the early twentieth century by an increasing control over reproduction and a rapid fall in birth rates.

46. Notwithstanding considerable variations between individual countries, the common view is that the demographic transition in the more developed countries was associated in a general but not necessarily well-defined manner with the whole complex of economic and social changes which these countries underwent in the course of the modern period. In the areas of European settlement, according to Davis, the demographic transition accompanied and was directly related to the industrial revolution as an economic and socio-cultural phenomenon.<sup>99</sup> Notestein, among others, stressed the importance of the whole process of modernization for the decline in mortality and the subsequent reduction of fertility in these coun-

tries.<sup>100</sup> Stolnitz emphasized the association between modern economic growth and the demographic transition in noting that all countries which in the modern period developed from a traditional, agrarian-based system to a largely industrial, urbanized base also moved from conditions of high mortality and fertility to low mortality and fertility.<sup>101</sup>

47. Of the two broad groups of determinants of mortality decline, economic and social development, on the one hand, and advances in medicine, public health and sanitation on the other,<sup>102</sup> the former are often thought to have been decisive particularly in the initial fall of mortality in the countries of early development and during the first part of the period of modern economic growth.<sup>103</sup> It has been asserted that, at the least, improvements in sanitation and public health and medical advances were not independent of economic and social development. Progress in the latter fields, according to this argument, made it possible to consolidate the improvements in mortality conditions attained through medical advances; and this view is shared even by most of those writers who stress such advances as the prime factors in mortality decline.<sup>104</sup> Like the decline in mortality in the more developed countries, that in fertility is thought to have been linked to the whole complex of economic and social

change in the course of the modern period. In general terms, the fall of fertility has been related to the over-all process of modernization and socio-economic change, with the time-lag in the decline of fertility compared with that in mortality being attributed to the slower response of the former to such changes.<sup>105</sup> The analysis of more specific determinants of past fertility declines—such as rising levels of living, the economic advantages of having a larger number of children as against the cost of their upbringing, the effects of industrialization and urbanization, to name but some of the factors—have produced a number of hypotheses on these interrelations,<sup>106</sup> and despite the fact that the concrete findings and evidence to support these assumptions are scarce, it is generally recognized that the complex of socio-economic determinants has had a decisive influence on fertility changes.

48. Although the demographic transition in the more developed countries may be assumed to have not been independent of modern economic growth, the nature of the arguments also suggests that the association was only a loose one. Several findings seem to confirm the lack of a consistent systematic relationship. For instance, indications are, as discussed in a different context, that a slow, but irregular, decline in death rates, attributable to the lowering of peaks in mortality, started before the process of industrialization and modern economic growth.<sup>107</sup> As to the factors in the initial decline in mortality during the modern period, Durand argued that whereas for Western European countries the fall in death rates could be explained, as postulated by the transition theory, by the improved mortality conditions following industrialization, such an explanation did not apply to Eastern Europe or areas of what is presently the Soviet Union where economic progress during the early period of modern economic growth was small, but population increased as fast as

in the West.<sup>108</sup> In the case of fertility, an analysis of its decline in European countries in relation to various economic, social and other factors and the diversity of conditions under which it occurred led to the conclusion that the process of fertility decline is a far more complex phenomenon than assumed in the transition theory.<sup>109</sup>

49. In contrast to the developed countries, most of which have completed the demographic cycle, the transition in the developing areas is only of recent origin and the majority of the less developed countries are at present in the stage of rapid transitional growth. In general, mortality and fertility in these countries is thought to have been high and remained so well into the twentieth century. Small but sustained improvements in mortality started to manifest themselves in a number of countries in the 1920s and 1930s,<sup>110</sup> and several writers have placed the beginnings of the transition process in the less developed part of the world in this period.<sup>111</sup> Significant declines in mortality in most of these countries, however, did not occur until after the Second World War,<sup>112</sup> but then the fall in death rates was faster than ever before and faster than had been considered possible only a few decades ago; in many of these countries initially high death rates were halved within a short period.<sup>113</sup> Little is known about historical levels of fertility in less developed countries, but recent estimates indicate that in the majority of them birth rates are high, both in absolute terms and in comparison with most more developed countries at the beginning of the modern period and that, with few exceptions, fertility has not shown any tendency to decline.<sup>114</sup> Conjectured and estimated birth rates for the less developed regions, since 1750 show virtually stable and high rates of the order of 40 per thousand throughout the modern period. Death rates in the less developed regions fluctuated considerably until the 1920s and then started to decline, with the largest gains occurring since 1950. The unprecedented fall in mortality while fertility remained stable caused the large and increasing "demographic gap" between births and deaths, characteristic of post-war population growth in the less developed regions (see again table XIV.2).

<sup>108</sup> Durand, "The modern expansion ..." (1967). For a more general discussion of the argument that the transition as it occurred in countries of Western Europe does not necessarily repeat itself in the same manner under different conditions, see chapter III, section H. <sup>114</sup> See chapter IV, section A.

50. Until the Second World War, the experience of the less developed countries was not unlike that of the European countries of early development during the initial stages of transition. Post-war trends in the less developed countries, however, led a number of writers to question the relevance of the demographic transition as it had occurred in the European countries for the presently developing countries.<sup>115</sup> The prevalence of high levels of fertility and mortality in these countries during most of the modern period may have reflected conditions similar, although not identical, to those existing in pre-industrial Europe.<sup>116</sup> The slow decline in death rates during the 1920s has been attributed to roughly the same group of factors which set off the initial fall in death rates in the more developed countries—such as the lower incidence of acute food shortages and famines, certain health and sanitation measures, the establishment of order and security, and a limited amount of economic progress.<sup>117</sup> These similarities no longer held for the post-war period. The exceptional fall in the death rates of the less developed countries in the last few decades responded to a great extent to factors different from those which predominated in the more developed countries in the past. In the latter group of countries, as has been noted before, the reduction of mortality is generally thought to have been linked to the whole process of modernization and economic and social change, or at least not to be independent of it. The recent steep mortality decline in the less developed countries has occurred, unlike in the past, in the absence of significant economic progress, and is considered to have been mainly the result of the spread of new techniques or techniques adapted from the more advanced countries in the fields of public health, sanitation and medicine.<sup>118</sup> Requiring relatively small resources, both human and financial, and not being dependent upon the slow process of economic and social change, large gains in longevity could be attained in a relatively short period. The acceleration of population growth due to this autonomous fall in mortality not only signified the reversal of the traditional, even though tenuous, association between population and economic growth; higher population growth became an obstacle to economic growth in so far as it did not by itself generate higher rates of economic growth.<sup>119</sup>

## 2. INDUSTRIALIZATION AND URBANIZATION IN THE PERIOD OF MODERN ECONOMIC GROWTH

### (a) *The changing industrial structure of the labour force*

51. The process of modern economic growth has been accompanied by important shifts in the industrial composition of the national product and labour force. Although historical data on the long-term trends in economic structure are limited, indirect evidence suggests that in pre-industrial societies agriculture absorbs by far the largest part of the working population. At the low levels of productivity and income characteristic of such societies most of the population must necessarily be engaged in providing the necessary food for its own subsistence, and the prevailing levels of production make it impossible to support more than a small number of persons in non-agricultural pursuits. General considerations of this type, as well as available data both for presently developed countries before they embarked on the process of economic growth and for less developed countries in their early stages of development, have led many writers to conclude that in pre-industrial societies the share of agriculture in the total labour force is of the order of 70 to 80 per cent or even higher.<sup>120</sup> Conjectures like these, it should be remembered, are, however, subject to a substantial margin of uncertainty since the lack of specialization and the virtual absence of a division of labour in primitive societies may severely limit the significance of any industrial or occupational classification.<sup>121</sup>

52. One of the predominant characteristics of modern economic growth is thus the transformation of the economic structure from one where agriculture absorbs as much as four fifths of the working population to one where industry and services employ as much as or more than nine tenths of the labour force. Even though some of the most advanced countries have completed such a transformation, according to Davis, changes in the industrial composition of labour on a world-wide basis were probably relatively small during the greater part of the modern period although, in his view, significant in a longer historical perspective.<sup>122</sup> Tentative as they are, Bairoch and Limbor's estimates of the industrial distribution of the labour force since 1900 in general tend to lend support to the assumption that, prior to the twentieth century, changes in the industrial structure of the labour force had been relatively small. Around 1900, the agricultural labour force still represented well over 70 per cent of the total working population. Mining, industry and construction, according to these estimates, accounted for considerably less than 15 per cent of the total working population, and commerce, transport and services for

nearly 15 per cent.<sup>123</sup> The high estimated share of the agricultural labour force in 1900 seems to confirm that over the preceding one and a half centuries changes in the industrial composition must have been modest. Since the beginning of this century, however, considerable shifts in the structure of the labour force occurred. Bairoch and Limbor estimated that by 1960 the proportion of the total labour force in agriculture had declined to somewhat over 58 per cent while the shares of mining, industry and construction had increased to nearly 19 per cent and that of commerce, transport and services to nearly 23 per cent.<sup>124</sup>

53. In addition, the pace of structural change appears to have accelerated. According to Bairoch and Limbor, between 1900 and 1920 the proportion of the world's labour force engaged in agriculture decreased by 2.6 per cent. In the next ten years it is thought to have declined nearly as much—2.4 per cent—as in the preceding twenty years and the estimated reduction of 5.6 per cent between 1930 and 1950 and of 3.4 per cent during the 1950s confirms the continued acceleration of the rate of structural change. Trends in each of the two other major sectors are less clear, but their combined shares, of course, increased at an accelerating rate.<sup>125</sup>

54. Given the close, although not necessarily fully defined, association between economic growth and development, on the one hand, and the industrial structure and its evolution, on the other, considerable differences may be expected to exist in the composition of the labour force between the economically more developed and less developed countries. Reliable statistical information on the industrial structure in the pre-modern period and during the phases of early development are available only for a limited number of developed countries.<sup>126</sup> Where they exist these data confirm the high share of agriculture in the total labour force and its decline during the period of modern economic growth.<sup>127</sup> It has been estimated

<sup>123</sup> Bairoch and Limbor, "Changes in the industrial distribution..." (1968). The authors stress that these estimates may be subject to a considerable margin of error.

<sup>124</sup> *Ibid.* Estimates for 1950 are also found in International Labour Office, "The world's working population..." (1956), and for 1950 and 1960 in Baum, "The world's labour force..." (1968), and in International Labour Office, *Labour Force Projections*, part V... (1971), table 3, p. 55. The lowest percentages for agriculture and the highest for the non-agricultural sectors are found in the earliest of these estimates. The later ones all implied an upward revision of the proportion corresponding to agriculture and decreases in the shares of industrial and service activities. See also chapter IX, section D.

<sup>125</sup> Bairoch and Limbor, "Changes in the industrial distribution..." (1968).

<sup>126</sup> Data on long-term trends in a number of individual countries have been brought together in Clark, *The Conditions of Economic Progress* (1957), chap. 9; Kuznets, "Quantitative aspects of the economic growth of nations. II..." (1957); his *Modern Economic Growth*... (1966), chap. 3; and his *Economic Growth of Nations*... (1971), chap. 6; Bairoch *et al.*, *The Working Population*... (1968). For references to studies on labour force structure and its evolution in individual countries see chap. IX, section D.

(1960); Cipolla, *The Economic History of World Population* (1962), pp. 24-25; Lewis, *The Theory of Economic Growth* (1963), pp. 333-334; Thompson and Lewis, *Population Problems* (1965), p. 402. See also Dovring, "The transformation of European agriculture" (1965) who notes that a pure agricultural society does not exist and probably never did.

<sup>121</sup> See section A of this chapter.

<sup>122</sup> Davis, "Population and the further spread..." (1951).

that, in the presently developed non-socialist countries, about 56 per cent of the working population was still engaged in agricultural activities by 1880, but that at the turn of the century this proportion had declined to less than half. Since then the percentage share of agriculture in these countries has been falling at an accelerated rate, with the exception of the period between 1930 and 1950.<sup>128</sup> Estimates for all presently developed countries (including the socialist countries) since 1900 suggest a similar pattern. They indicate that at the beginning of the century nearly three fifths of the total working population was still found in agriculture, but that since then this proportion has fallen at an increasing rate so that by 1960 it was half of what it was at the beginning of the century. They also suggest a speeding-up in the growth of the combined share of mining, industry and construction, which in 1960 reached about 33 per cent, nearly one and a half times as high as it was in 1900 (less than 22 per cent). Large, but varying increases were found in the combined shares of commerce, transport and services so that, over the period considered, the corresponding proportion nearly doubled—from 19 to 36 per cent.<sup>129</sup>

55. Compared to the evolution in the more developed countries, the structure of the labour force in the less developed countries experienced only relatively small changes in the course of the present century. Around 1900, according to Bairoch and Limbor, the share of agriculture in their total labour force was estimated to be close to 80 per cent, a figure which leaves little room for substantial change in previous periods. This proportion has declined since that time and was estimated by these authors to have been 75 per cent in 1950 and decreased further to approximately 73 per cent by 1960. The estimates also suggest that for the greater part of this period the relative decrease in agriculture was brought about to a very large extent by an increase in activities of the service type, whereas the proportion in mining, manufacturing and construction remained relatively stable until 1950, after which year it experienced a substantial increase.<sup>130</sup>

56. Although the relative share of agriculture in the world's labour force has been decreasing for a considerable time, the absolute number of agricultural workers continued to grow substantially. Even in the case of the more developed countries this number probably did not decrease until the 1920s.<sup>131</sup> Since then up to 1960, the

agricultural labour force in the more developed countries, excluding the Soviet Union and Eastern Europe, may have fallen by some 20 million.<sup>132</sup> Between 1950 and 1960, according to Baum, the decrease was especially great, amounting to possibly as much as 10 million.<sup>133</sup> In contrast, the size of the agricultural labour force in the less developed regions continued to increase and did so at an accelerated rate. The estimated increase of some 60 million in the number of agricultural workers in the less developed regions, excluding the Asian socialist countries, between 1950 and 1960 was higher than that experienced during the twenty years from 1930 to 1950.<sup>134</sup>

### (b) Industrialization and urbanization

57. The structural and spatial changes in the economy which manifest themselves primarily in the shifts in the industrial composition of the labour force and the rural-urban distribution of the population are, as noted before, closely interrelated.<sup>135</sup> Nevertheless, relatively little is known about the actual trends in industrialization and urbanization during the period of modern economic growth and even less about the interrelations between them as they existed during this period. In general terms, it has been observed that, although cities have existed in some form since early times, their rapid growth over the last centuries was made possible by, and resulted from the technological development, economic and social change associated with modern economic growth.<sup>136</sup> The agricultural and industrial revolutions ended the traditional predominance of the agricultural and rural sector and created the conditions as well as the need for large transfers of rural agricultural workers to urban, industrial occupations.<sup>137</sup>

58. As discussed in more detail in chapter VI, the process of urbanization during the modern period was rapid. The population living in localities of 20,000 inhabitants or more in 1800 was estimated to have been some 22 million, representing 2.4 per cent of the population at that time. Between 1800 and 1950, the population in localities of that size multiplied some 23 times, to over 500 million, while the total world population increased 2.6 times. The proportion of the total population living in localities of 20,000 inhabitants and over multiplied nearly ninefold to reach over 20 per cent. The growth of urban population during this period was both rapid and accelerating. Urban population in the sense defined here is estimated

<sup>128</sup> Bairoch and Limbor, "Changes in the industrial distribution ..." (1968). The countries include Europe (with the exception of Eastern Europe and excluding the Soviet Union); Canada and the United States; Japan; Australia and New Zealand; and the Republic of South Africa. The authors note that in some of these countries (such as Finland, Italy, Portugal, Spain and Turkey) the share of agriculture in the total labour force is still comparatively high.

<sup>129</sup> Bairoch and Limbor, "Changes in the industrial distribution ..." (1968). The estimates for 1960 differ somewhat from other estimates, cited earlier, prepared for that year.

<sup>130</sup> Bairoch and Limbor, "Changes in the industrial distribution ..." (1960), table 6. See also Bairoch, *Diagnostic de l'évolution économique du tiers-monde* ... (1969), pp. 205-210. The other estimates for 1950 and 1960 referred to earlier differ somewhat from those cited here.

(1955), and his "Historical aspects of urbanization" (1965); United Nations, *Report on the World Social Situation* ... (1957), pp. 113-114; Hauser, "World and Asian urbanization ..." (1957), and his "Urbanization: an overview" (1965); Hawley, "World urbanization ..." (1964).

<sup>137</sup> Fisher, "The economic implications ..." (1935); Clark, *The Conditions of Economic Progress* (1957), p. 492; Fourastié, *Le grand espoir du XX<sup>e</sup> siècle* (1949), chap. 2; Kuznets, *Toward a Theory* ... (1965), pp. 25 ff.

to have increased by nearly two times between 1850 and 1900 and by nearly two and a half times from 1900 to 1950.<sup>138</sup> Rapid urbanization continued through the recent period. The world's total population living in agglomerations of 20,000 inhabitants and over was estimated to have increased from somewhat over 14 per cent in 1920 to over 25 per cent by 1960 and projections suggest that by 1970 this proportion may have increased to over 28 per cent.<sup>139</sup>

59. Estimates on historical levels and trends of urbanization in more developed and less developed regions are scarce, but suggest in general that in both groups of countries urbanization was not far advanced in the beginning of the nineteenth century and that the present large differences between them have since emerged.<sup>140</sup> The estimated proportion of the population in cities of 100,000 inhabitants and over in 1800 was uniformly low in all of the continents of the world. Since then and continuing into the twentieth century, the growth of large cities was especially rapid in the more developed regions. The population of the large cities of America, Europe, Oceania and the Soviet Union increased about 35 times between 1800 and 1950, compared with a tenfold rise in Asia.<sup>141</sup> Urban growth in the more developed continents was, however, uneven and has tended to slow down in the more recent period especially as a result of trends in Europe. It has been estimated that the large-city population of these regions multiplied nearly three times between 1800 and 1850 and about four and a half times between 1850 and 1900, but that between 1900 and 1950 the multiplication factor declined to about three times.<sup>142</sup>

60. Thus while it is generally inferred that during the modern period as a whole the substantial structural changes in the presently developed countries were accompanied by rapid urban growth,<sup>143</sup> more recent trends only partly confirm the existence of such a close association. Although levels of both industrialization and urbanization in these countries increased considerably since the beginning of the twentieth century, the estimates cited also suggest that while the share of the agricultural labour force has been decreasing at an accelerating rate,

the rate of urbanization in most of these countries may have slowed down or remained fairly stable.<sup>144</sup>

61. The growth of urban population of the less developed regions in the nineteenth century, although probably higher than before, remained relatively slow and far below the very rapid increase in the more developed regions. The population in cities of 100,000 inhabitants and over in Africa and Asia is estimated to have increased only by one fourth between 1800 and 1850 and by two thirds between 1850 and 1900. Since 1900 urban growth in these continents accelerated strongly: in 1950 their large city population was five and a half times as high as at the beginning of the century, surpassing by far the increase in the other continents. This speeding-up of urban growth is confirmed by recent, more detailed data for the presently less developed regions as a whole: between 1920 and 1940 cities with 100,000 and more inhabitants in these regions increased by more than 120 per cent and between 1940 and 1960 the increase was nearly 200 per cent. Even so, levels of urbanization in the economically less advanced regions are still considerably below those of the more advanced countries and while in the majority of the latter the absolute size of the rural population has remained relatively constant or declined in recent decades, in the less developed countries rural population has continued to grow at a substantial rate, although lower than in the urban areas.<sup>145</sup> Knowledge as to the relative pace of and interrelations between industrialization and urbanization in these countries is relatively scarce. What evidence there is, according to many authors, suggests that, as a result of the combined effect of rapid natural increase and migration, the urban population has reached levels in excess of what would be commensurate with their stage of industrialization and higher than those found in the presently developed countries at a similar stage of development.<sup>146</sup>

### C. Recent evolution and situation

62. Both from the point of view of economic growth and demographic trends, the recent decades have been a period of great changes which distinguish them from earlier periods. As far as population growth is concerned, the decades since the 1940s witnessed a strong acceleration in world population growth and an increasing gap between the rates of increase in the less developed and more developed countries. During the same period, both developed and developing countries embarked on a phase of rapid growth of production, which especially in the latter of the two signified in most cases a break with the earlier periods of slow expansion or virtual stagnation. Nevertheless, despite this considerable acceleration in

<sup>138</sup> See chapter VI, section C.

<sup>139</sup> See again chapter VI, section C, and for the projected value in 1970, United Nations, *Growth of the World's Urban and Rural Population* . . . (1969), table 31, p. 58.

<sup>140</sup> Davis and Hertz Golden, "Urbanization and the development of pre-industrial areas" (1954). See also United Nations, *Report on the World Social Situation* . . . (1957), table 3, p. 114.

<sup>141</sup> See chapter VI, section C, table VI.5. Also Hauser, "World and Asian urbanization . . ." (1957); United Nations, *Report on the World Social Situation* . . . (1957), p. 114; Hoyt, "The growth of cities from 1800 to 1960 . . ." (1963).

<sup>142</sup> Hauser, "World and Asian urbanization . . ." (1957); United Nations, *Report on the World Social Situation* . . . (1957), p. 114. See also Davis and Hertz Golden, "Urbanization and the development of pre-industrial areas" (1955); Davis, "The origin and growth of urbanization . . ." (1955).

<sup>143</sup> Davis and Hertz Golden, "The world distribution of urbanization" (1951); Davis, "The origin and growth of urbanization . . ." (1955); Hoselitz, "The role of cities in the economic growth . . ." (1953).

<sup>144</sup> The possibility of a changing relationship over time between industrialization and urbanization has received some empirical report. Sovani, "The analysis of over-urbanization" (1964) found, on the basis of data for a number of more developed countries, a much lower correlation coefficient between the proportion of the labour force engaged in non-agricultural activities and the proportion urban in 1950 than in 1891. See section C.

<sup>145</sup> For further discussion and data see chapter VI, section C and tables VI.5 and VI.7.

<sup>146</sup> See section C below.

levels of production in the economically less advanced countries, the large differences in levels of *per capita* income between them and the economically more advanced countries have shown no tendency to decline, but, on the contrary, widened.

# 1. ECONOMIC GROWTH AND DEMOGRAPHIC CHANGE IN THE POST-WAR PERIOD

## (a) *Growth of income*

63. As discussed in the preceding section, despite the scarcity of estimates of *per capita* income on a world-wide basis for the period prior to the Second World War, the great gap in income between the more developed and less developed regions was evident. Both Kuznets<sup>147</sup> and Deane<sup>148</sup> compiled data on relative *per capita* income in different regions of the world for 1938 which give some indication of the disparities in income levels at the time. Taking the average world income as 100, the index for North America and Oceania was 420, for Western Europe 275, for the Soviet Union 102 and for the other European countries 129. In contrast, the indices for the predominantly less developed regions were all below 100: for Latin America it was 71 and for Asia and Africa 33 and 32, respectively (see tables XIV.3 and XIV.4). Developments during the 1940s were greatly affected by the war and its aftermath and although data on growth of total and *per capita* domestic product for this period showed considerable variations for regions and individual countries, they suggest that on the whole the difference in income levels between the more industrialized and less industrialized countries widened. According to estimates, which exclude the Soviet Union and Eastern Europe, between 1938 and 1948 the gross domestic product of the less industrialized countries grew at an average rate of 2.9 per cent annually, which was only slightly below that of the more industrialized nations, 3.1 per cent. However, because of the faster growth of population in the former—1.4 per cent annually as against 1.0 per cent in the more advanced countries—growth rates of *per capita* product diverged considerably. In the more industrialized countries the rate of increase in *per capita* gross domestic product was 2.1 per cent annually, while in the less industrialized it amounted to only 1.5 per cent.<sup>149</sup>

64. The large relative gap in income levels between the more developed and less developed regions at the beginning of the 1950s is revealed by Kuznets's estimates of indices of relative *per capita* income in 1949 for the same regions as in 1938 (table XIV.3). The index of *per capita* income of the most developed regions—North America and Oceania—was nearly thirty times that of the world's poorest region, Asia; somewhat less than twenty-five

<sup>d</sup> South of the United States, including the Caribbean.

times that of Africa and still nine times that of Latin America. The *per capita* income ratio between the more developed regions of America, Europe and Oceania combined and the less developed regions, formed by Africa, Asia and Latin America—calculated on the basis of the income indices for regions and their share in the total population—was at that time more than 10 to 1.<sup>150</sup> Another series of estimates of population and income in major regions for 1949 suggests a somewhat lower margin between income levels in the most and least advanced regions. Average *per capita* income in the more developed regions (Europe, North America, Oceania and the USSR), according to these estimates, was somewhat less than 10 times as high as in the less developed regions (Africa, Asia and Latin America).<sup>151</sup> However, the estimated *per capita* gross domestic product of the developed market economies of North America and Europe and the then emerging Japan in 1950 was estimated to have been over ten times that of the less developed regions.<sup>152</sup> A ratio of 10 to 1 between the *per capita* income of the average more developed and less developed countries appears thus to have existed around 1950.

65. Since the post-war period, growth in total income and income per head have varied both in the more developed and less developed countries and whereas in some years total production may have expanded faster in the one or the other, on the whole it increased at a fairly similar rate in both groups of countries. But with population growing much faster in the developing countries, their

SOURCE: Deane, "The long-term trends ..." (1961).

relative gains in *per capita* income remained in most years below that of the economically more advanced countries. In absolute terms, increases in income per head in the developing countries were at all times only a very small amount compared with the increases found in the more developed countries.

66. Both more developed and less developed countries experienced a rapid growth of production in the early 1950s. Rough estimates of commodity output in the period 1948-1955, for market economies only, suggest that in this period the production of agriculture, mining and manufacturing in all countries considered increased by 30 per cent, while the corresponding relative increases were 31 per cent in the more developed and 26 per cent in the less developed countries.<sup>153</sup> According to another estimate, gross domestic product in the years between 1950 and 1955 increased at virtually the same rate in the more and in the less developed market economies, the figures being 4.7 and 4.6 per cent, respectively.<sup>154</sup> Despite the similarity in growth of total commodity output and of gross domestic product, *per capita* increases in the less developed countries remained, because of the more rapid growth of their population, considerably below those of the more developed countries. Thus while the commodity output per head of the less developed market economies increased by 15 per cent between 1948 and 1955, in the more developed ones the rise was 22 per cent.<sup>155</sup> Likewise, in the period 1950-1955, *per capita* gross domestic product in the less developed market economies expanded at a rate of 2.5 per cent as compared with 3.4 per cent in the economically more advanced countries.<sup>156</sup>

67. Economic growth in the developed market economies, and especially in the United States, slowed down during the latter half of the 1950s, when the gross domestic product of these countries is estimated to have increased

<sup>153</sup> United Nations, *World Economic Survey, 1955* (1956), table 1, p. 25.

<sup>154</sup> United Nations, *World Economic Survey, 1963*, part I ... (1964), table 2-1, p. 19.

<sup>155</sup> United Nations, *World Economic Survey, 1955* (1956), table 1, p. 25.

<sup>156</sup> United Nations, *World Economic Survey, 1963*, part I ... (1964), table 2-3, p. 21. For data on the growth of net domestic product in major regions between 1950 and 1955 see also, Kristensen *et al.*, *The Economic World Balance* (1960), pp. 25, 250.

at an average annual compound rate of 3.3 per cent compared with 4.7 per cent in the preceding quinquennium. In the less developed market economies, gross domestic product increased, according to various estimates, at a rate of the order of 4.3 to 4.6 per cent. The corresponding estimated increases in product per head varied between 1.8 and 2.3 per cent for the developing countries and amounted to 2.0 per cent in the more developed. Despite the fact that thus, in *per capita* terms, economic growth in these years was similar in both groups of countries, in absolute terms the average gain in *per capita* income in the less advanced countries—10 to 15 dollars over the five-year period—was only a fraction of the average increase of over 130 dollars in the more developed countries.<sup>157</sup>

68. The income gap thus widened in these years: according to the estimates cited, *per capita* product in the developed market economies was in 1955 well over 10 times that of the developing countries.<sup>158</sup> Hagen, using estimates of *per capita* gross national product for 1957, found on the basis of these data that the poorest half of the world's population had a *per capita* income which represented only one thirty-fifth of that of the United States. He also noted, however, that conventional methods of international comparisons of income by means of rates of exchange tend to over-estimate the income differential. If income is assessed by direct comparison of prices instead of the use of foreign exchange rates, the difference becomes considerably smaller. Using rough estimates for conversion, he concluded that the 50 per cent of the population at the bottom of the income pyramid had a *per capita* income one-twelfth, instead of one thirty-fifth, of that of the United States.<sup>159</sup>

69. By the end of the 1950s *per capita* income in the developed countries is estimated to have been nearly eleven times that of the developing countries as compared with somewhat over ten times in 1950.<sup>160</sup> Indices of relative *per capita* income for major regions in 1961 were prepared by Deane (see table XIV.4). Setting the world *per capita* income at 100, the index for North America and Oceania was 542 and for Europe (including Asiatic USSR) 181. In contrast the index for Latin America was 69, for Asia 23 and for Africa 22. Compared with the pre-war estimates, gains in relative incomes were limited to the two more developed regions, while the indices for all three predominantly less developed regions declined.

<sup>157</sup> United Nations, *World Economic Survey, 1963*, part I ... (1964), tables 2-1 and 2-3, pp. 19, 21, gives a rate of growth of total gross domestic product for the developing market economies of 4.3 per cent and a *per capita* increase of 1.8 per cent. Hagen and Hawrylyshyn, "Analysis of world income and growth ..." (1969), give rates of 4.4 and 1.8, respectively. United Nations, *World Economic Survey, 1967*, part I ... (1968), table 2, p. 17, using a broader range of data than the 1963 survey, estimated the total gross domestic product of the developing countries to have increased at 4.6 per cent and the *per capita* product at 2.3 per cent. Estimates for the more developed market economies were similar in all three sources.

<sup>158</sup> United Nations, *World Economic Survey, 1963*, part I ... (1964), table 2-3, p. 21.

<sup>159</sup> Hagen, "Some facts about income levels ..." (1960); also his "World economic trends ..." (1958).

<sup>160</sup> United Nations, *World Economic Survey, 1963*, part I ... (1964), table 2-3, p. 21.

In addition, however, the largest increases since 1938 are found in the most developed regions and the largest losses in the poorest regions, implying not only that the average income levels between more and less developed regions widened, but that also the gap between the poorest and richest became larger.<sup>161</sup>

70. In the period 1960-1965, the real gross domestic product of the developing countries has been estimated to have risen at a rate not unlike that of the second half of the 1950s, the estimates varying between 4.4 and 4.7 per cent. In contrast, in the developed market economies production expanded faster than in the previous five years and gross domestic product increased at a rate only slightly below 5 per cent. Because of this acceleration in economic growth and the moderate and somewhat lower rate of population growth compared with the 1950s, *per capita* product increased 3.6 per cent annually in these countries. In the absence of a comparable speeding-up of economic growth, while population growth accelerated, the annual percentage gain in *per capita* product in the developing countries remained below 2 per cent, only little more than half of that of the more developed countries.<sup>162</sup> Available data suggest, however, that in the latter part of the 1960s production in the developing nations rose faster than in the preceding years. Gross domestic product of these countries was estimated to have grown at an annual rate of 4.7 to 4.8 per cent in 1960-1967 and by 6.1 per cent in 1967-1968. Faster growth was also found in the more developed market economies in recent years: in 1960-1967 their gross domestic product increased annually by 5.2 per cent on the average, whereas in 1967-1968 it rose by some 5.6 to 5.7 per cent.<sup>163</sup>

71. Because of the different concepts used in measuring economic growth, the possibilities of comparing economic performance in the predominantly market economies and the centrally planned economies are very limited. Comparisons of growth trends in these two groups of countries are especially scarce for the early post-war period, but for more recent years some comparable estimates of economic growth in the socialist and market economies are available. On the whole, economic growth in the centrally planned economies appears to have been more rapid than in the market economies. A direct comparison of the growth of gross domestic product in the developed countries of Western Europe and of net material product<sup>164</sup> in the centrally planned economies of Eastern Europe led to the conclusion that during the 1950s the latter expanded faster than the market economies. This

conclusion was not significantly altered when allowance was made for differences in concepts, by means of growth comparisons of net material product estimates prepared for some Western European countries with the net material products of Eastern European countries, or vice versa, by estimating gross domestic product in some Eastern European countries. With few exceptions, the pace of economic development in Eastern Europe for the period 1949-1959 was found to be considerably faster than in Western Europe.<sup>165</sup>

72. Estimates of the levels and trends of total and *per capita* gross domestic product for the socialist, as well as the market economies, especially for the period 1955-1960, were prepared by Hagen and Hawrylyshyn. These data confirm the continued faster economic growth in the socialist countries: gross domestic product in European and Asian socialist countries increased in this period at an estimated rate of 6.4 per cent annually, whereas the corresponding estimate for all market economies together was only 3.6 per cent. Significant differences in growth trends were found, however, within the socialist countries. The estimates for the Asian socialist countries imply a rate of growth of gross domestic product of 7.8 per cent annually. The less developed European socialist countries—which according to these authors consist of Albania and Yugoslavia—experienced a rate of growth of gross domestic product of 6.5 per cent and the remaining more developed European socialist countries one of 6.0 per cent. Large differences also existed as far as growth in *per capita* product was concerned. For all socialist countries combined, *per capita* product in this period is estimated to have increased at a rate of 4.9 per cent annually; in the Asian socialist countries the rate was estimated at 6.3; in the less developed European countries 5.4; and in the more developed European socialist countries 4.6 per cent.<sup>166</sup>

73. Data for the European socialist countries suggest a continued rapid growth of income in the 1960s. Total gross domestic product was estimated to have increased at a rate of 6.6 per cent annually between 1960-1967 and 7.0 per cent in 1967-1968.<sup>167</sup> In comparison, gross domestic product of the developed market economies increased, as noted before, at a rate of 5.2 per cent in 1960-1967 and by 5.6 per cent between 1967-1968. On the whole, economic growth of the socialist countries during the post-war period appears to have been considerably faster than in the rest of the world. As far as the European socialist countries are concerned, it was estimated that,

<sup>161</sup> Deane, "The long-term trends ..." (1961).

<sup>162</sup> United Nations, *World Economic Survey, 1967*, part I ... (1968), table 2, p. 17, which estimated the rate of growth of gross domestic product in the developing countries to have been 4.4 per cent. Hagen and Hawrylyshyn, "Analysis of world income and growth ..." (1969), reached the figure of 4.7 per cent.

<sup>163</sup> United Nations, *World Economic Survey, 1968*, part II ... (1969), table 1, p. 2; ———, *World Economic Survey, 1969-1970* ... (1971), table A.1, pp. 177-179.

<sup>164</sup> In simple terms, material product may be said to include, in principle, only the production, transport and distribution of goods (excluding retailing) and to exclude other services and rent. In practice, it may include all transport and distribution. See United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1961*, part II ... (1964), chap. 1, p. 4.

<sup>165</sup> United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1961*, part II ... (1964), chap. 2, pp. 10-12.

<sup>166</sup> Hagen and Hawrylyshyn, "Analysis of world income and growth ..." (1969).

<sup>167</sup> United Nations, *World Economic Survey, 1968*, part II ... (1970), table 1, p. 2; ———, *World Economic Survey, 1969-1970* (1971), table A.1, p. 179. However, Hagen and Hawrylyshyn, "Analysis of world income and growth ..." (1969), estimated that during 1960-1965 total and *per capita* gross domestic product in the more developed European socialist countries increased much more slowly, the figures being 4.7 for total and 3.4 for *per capita* product. Growth in the less developed European socialist countries, according to their estimates, remained high, the annual growth rates being 6.6 for total and 5.3 for *per capita* gross domestic product.

TABLE XIV.5. ESTIMATES OF POPULATION OF THE WORLD AND MORE DEVELOPED AND LESS DEVELOPED REGIONS, AND DECENNIAL INCREASES, 1920-1970

	World		More developed regions		Less developed regions	
	Population (millions)	Increase in preceding decade (percentage)	Population (millions)	Increase in preceding decade (percentage)	Population (millions)	Increase in preceding decade (percentage)

SOURCES: 1920-1940 data from United Nations, *World Population Prospects* ... (1966), table 6.1, p. 23; 1950-1970 data from *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

<sup>a</sup> Projected figure.

between 1950 and 1967, their total product increased at an average annual rate of 7.0 per cent and their *per capita* product at a rate of 5.6 per cent annually.<sup>168</sup>

74. Despite the fact that, during the considerable period which has elapsed since the Second World War, the developing countries have experienced rates of growth of their total income which in historical perspective were quite high and probably never had occurred before for any extended period in their history, the accomplishment in terms of the absolute increases in *per capita* income was only moderate and their position in fact deteriorated in comparison with the progress in the economically more advanced countries. According to the available estimates, toward the end of the 1960s the *per capita* income of the less developed market economies remained well below 200 dollars and that for the less developed centrally planned economies was not much more than 100 dollars. In contrast, the level of *per capita* income in the more developed market economies was estimated to be over 2,200 dollars, or about twelve times that of the less developed market economies, while in the more developed centrally planned economies the *per capita* income of nearly 1,200 dollars was also some ten times that of the less developed centrally planned economies.<sup>169</sup>

#### (b) Demographic trends

75. The post-war period constitutes not only what may appear to be a distinct phase in economic trends, but it also was characterized by an unprecedented growth in population. World population, which increased by 10 per cent or somewhat more in each decade between 1920 and 1940, has grown at an accelerating rate since then. The world's population increased by 20 per cent between 1950 and 1960 and is estimated to have grown 22 per cent between 1960 and 1970. This increase implies an average annual rate of growth of 2 per cent, which

would result in a doubling of the population each 35 years, compared with an average annual rate of growth in the two pre-war decades of 1 per cent, a rate which means a doubling of the population each 70 years. In absolute terms, the world's population increased by around 200 million persons in each decade between 1920 and 1940, but is estimated to have grown nearly 500 million between 1950 and 1960 and nearly as much as 650 million between 1960 and 1970<sup>170</sup> (see table XIV.6).

76. The recent period stands out not only because of the rapid growth of world population but also because it implied a reversal of historical trends, when population in the more developed regions increased faster to a situation where the higher growth was found in the less developed countries. As noted in section B, population has increased faster in the less developed regions since the 1930s, but a large differential emerged only in the post-war period, owing to the very high rates of growth in the less developed regions, which also dominated world population trends. In the 1950s, when population growth rates in the more developed regions returned to levels similar to those prevailing prior to the 1930s—resulting in a decennial increase of 120 million or 14 per cent—rates of growth in the less developed regions had already started to accelerate. Between 1950 and 1960 the combined population of the less developed countries increased by some 375 million, or 23 per cent. Between 1960 and 1970 a further acceleration in growth took place in these countries. The estimated increase of some 535 million over the decade implies a relative increase of about 27 per cent. During that same period, growth in the more developed regions slowed down to 11 per cent and an absolute increase of somewhat less than 115 million (table XIV.5).

77. The extent of the acceleration of population growth in the less developed regions and its predominant role in world population trends over the last two decades is evident from a comparison with the two decades preceding the war. Between 1920 and 1940 the population of the

<sup>c</sup> Includes commerce, transport, storage and communication, services.

more developed and less developed regions increased by rather similar percentages (22 and 24 per cent). The average annual increase of the world population was some 22 million, of which about 7.5 million occurred in the more developed regions and somewhat less than 14.5 million in the less developed regions. From 1950 to 1970 the estimated increase of population in the more developed regions—26 per cent—was not much different from that for the pre-war period. In the less developed regions, however, the population is estimated to have increased in the same period by 52 per cent, or more than twice the percentage increase of 1920 to 1940, and double that for the more developed regions during 1950 to 1970. World population, dominated largely by the trend in the less developed regions, increased by about 46 per cent between 1950 and 1970, or twice as much as the relative growth in the twenty years before 1940. The average annual increase in the world's population during the two most recent decades was about 57 million of which 12 million was in the more developed regions and the remaining 45 million in the less developed regions. Between 1960 and 1970, it has been estimated, the average annual increment in the world's population has been of the order of 65 million, of which about 10 million in the more developed regions and 54 million in the less developed regions.<sup>171</sup>

78. Trends in world population growth are the result of the world-wide evolution of fertility and mortality. To a large extent the same is true for recent trends in the more developed and less developed regions. Although, especially in earlier periods, international migrations have been important as a determinant of population growth in a number of individual countries, they have most likely had only a relatively small importance so far as recent trends in the two major groups of regions are concerned.<sup>172</sup>

79. World demographic trends since the Second World War have been dominated by the decline of mortal-

ity in the less developed countries while their fertility remained relatively stable. In the more developed countries fertility and mortality declined only slowly and showed a tendency towards stabilization and convergence.<sup>173</sup> Crude birth rates for the more developed regions as a whole were estimated to have been around 22 per thousand persons between 1950 and 1960 and to have declined somewhat to 20 per thousand in the 1960s. The crude death rates in these countries, which were comparatively high during the 1940s, decreased to about 10 per thousand in the 1950s and were about 9 per thousand in the 1960s (table XIV.2). In the less developed countries fertility maintained its traditionally high level and long-term estimates of crude birth rates reveal relatively stable rates of somewhat over 40 per thousand continuing through the post-war period.<sup>174</sup> In contrast, mortality in this group of countries decreased at an unprecedented rate during this period. Crude death rates, which had been declining slowly for some time, were estimated to be still near 30 per thousand between 1920 and 1950. During the 1950s the death rate declined by about one fifth from an estimated 28 to 22 per thousand and between 1960 and 1970 it further decreased by about the same proportion to 17 per thousand (table XIV.2).

80. High fertility and declining mortality in the developing countries resulted not only in rapid population growth but also in an age distribution which compares unfavourably with that of the economically more advanced countries. According to estimates for 1965, nearly 42 per cent of the population in the less developed regions was below 15 years of age and 3.3 per cent was 65 years and over. The population in the intermediate group, from 15 to 64 years, which comprises the population in working ages, represented somewhat over 55 per cent of the total. In the more developed regions, however, the latter group accounted for 63 per cent of the total, while persons in the dependent age groups under 15 and 65 and over represented about 28 and 9 per cent, respectively.<sup>175</sup> The higher dependency burden in the less developed regions, is, as has been discussed before, generally thought to affect unfavourably the prospects for rapid economic growth both because of the heavier burden it places on

<sup>171</sup> United Nations, *The World Population Situation in 1970* (1971), pp. 3-5.

<sup>172</sup> See United Nations, *World Population Prospects ...* (1966), pp. 4-5. Also chapter VII, section D. This does not mean, however, that international migrations have had no effect at all. While small in absolute number, the migration of technical and professional workers from less developed to more developed regions has had an impact on human resources which has received considerable attention.

<sup>173</sup> See chapter IV, section A and chapter V, section A.

<sup>174</sup> See table XIV.2.

the working population as well because of the needs created by a large youth population.<sup>176</sup>

(c) *Structural change and urban growth*

81. As has already been noted in the preceding section, the pace of change in the employment and production structure has quickened since the beginning of the century and rapid economic growth in recent decades has been accompanied by considerable changes in both. Estimates of the industrial structure of the world's labour force between 1900 and 1960, prepared by Bairoch and Limbor, provide evidence of this speeding-up of the process of structural change in employment<sup>177</sup> (see table XIV.6) and various, but differing, estimates of the industrial structure of the labour force in 1950 and 1960, all confirm considerable changes during the recent period.<sup>178</sup> According to the most recent estimates of the International Labour Office the proportion of the labour force in agriculture declined from about 64 per cent in 1950 to less than 58 per cent in 1960. The share of industry increased from some 16 to over 20 per cent, an increase which surpassed that for the services sectors, for which the percentage was somewhat over 19 in 1950 and about 22 in 1960.<sup>179</sup> The long-term estimates of Bairoch and Limbor not only confirm a more rapid growth of the non-agricultural sectors between 1950 and 1960, but also suggest a shift in the growth patterns of the non-agricultural sectors as, until 1950, employment in the services sector appears to have grown considerably more rapidly than that in industries, a trend which, as noted, was reversed since the 1950s (see again table XIV.6).

82. Despite the recent rapid economic growth and the large scope for structural change in the less developed countries, the available estimates suggest that, on the whole, shifts in the employment structure during the past decades have been greater in the more developed countries (table XIV.6). Data for this latter group for 1950 and 1960 indicate, first, a sharp decline in the relative share of agriculture and, second, in contrast to world-wide trends, a rapid increase of employment, especially in the services sector. The estimates by Baum imply a decrease of more than 6 percentage points in the share of agriculture, while the estimates by Bairoch and Limbor show an even larger decline of 8 per cent. The former estimated an increase of over 4 per cent in the share of the services sector compared with one of over 2 per cent for industries, while Bairoch and Limbor estimated that the proportion in the services sector rose by 4.4 per cent,

whereas that for the industrial sectors increased by 3.7 per cent.<sup>180</sup>

83. Changes in the industrial distribution of the labour force in the less developed regions as a whole, were not very great during the 1950s, although they exceeded those in the preceding decades. The proportion of the labour force in agriculture declined by about 2 per cent, both according to the estimates of Baum, and those by Bairoch and Limbor. The estimated distribution of the increase in the non-agricultural labour force between secondary and tertiary sectors diverged, however, in one important aspect from the pre-war trends. Whereas prior to 1950 additions to the non-agricultural labour force apparently accrued mostly to the services sector (see table XIV.6), between 1950 and 1960 the percentage share of this sector remained virtually stable (at somewhat over 16 per cent according to Baum and less than 16 per cent according to Bairoch and Limbor). The increase in the relative share of the non-agricultural labour force during the 1950s is estimated to have occurred nearly entirely in the industrial sector. The percentage of the total labour force in this sector rose from about 9 to 11 per cent.<sup>181</sup>

84. Population and economic growth in the post-war period were associated with rapid urban growth and an accelerated urbanization. Between 1950 and 1960, when the world's population increased by somewhat less than 19 per cent, the "agglomerated population"—defined as that living in localities of 20,000 or more inhabitants—grew by nearly 43 per cent. The speeding up of urban growth is evident from a comparison with earlier periods: decennial increases between 1920 and 1950 varied from 24 to 28 per cent, approximately.<sup>182</sup> As noted earlier,<sup>183</sup> urban populations have increased especially rapidly in recent decades in the less developed regions, while urban growth in the more developed regions has shown a tendency to slow down since the beginning of this century. In the latter group of countries, the decennial increases averaged about 24 per cent during the 1920s and 1930s, declined to 13 per cent in the 1940s, but rose again to 31 per cent between 1950 and 1960. In comparison, urban growth rates in the less developed regions rose during each decade, a sharp acceleration occurring between 1950 and 1960 when the agglomerated population increased by 64 per cent.<sup>184</sup> Of course the level of urbanization in the less developed regions still remained well below that of the more developed regions. In 1960, about 46 per cent of the total population of the latter lived in localities of 20,000 or more inhabitants, whereas the corresponding proportion in the less developed regions was barely one third, 15.4 per cent (table VI.6).

<sup>176</sup> See chapter XIV.

<sup>177</sup> Bairoch and Limbor, "Changes in the industrial distribution ..." (1968).

<sup>178</sup> Apart from those cited by Bairoch and Limbor, estimates of the industrial distribution of the labour force in 1950 and 1960 are found in Baum, "The world's labour force ..." (1967); International Labour Office, *Labour Force Projections*, part 5 ... (1971), table 3, p. 55. Estimates for 1950 are also found in International Labour Office, "The world's working population ..." (1956). Estimates of the occupational distribution in 1960 and projections to 1980 are found in International Labour Office, "The occupational structure of employment ..." (1969).

<sup>179</sup> International Labour Office, *Labour Force Projections*, part 5 ... (1971), table 3, p. 55.

<sup>180</sup> Baum, "The world's labour force ..." (1967); Bairoch and Limbor, "Changes in the industrial distribution ..." (1968). On the basis of data for 1966, the latter authors infer that the decline in the share of the agricultural labour force has been even more rapid since 1960.

<sup>184</sup> See table VI.6.

## 2. SOME IMPLICATIONS AND ASSOCIATIONS OF RECENT ECONOMIC AND DEMOGRAPHIC TRENDS

### (a) *The relative spread of under-development*

85. The inversion of the traditional positive association between economic and population growth and the higher rates of population growth characteristic of the economically less advanced countries have had various implications for the development outlook both of individual countries and the developing countries as a whole. Given a more rapid increase in population, a smaller rise of *per capita* income will result from a given level of growth of total production. As far as the latter is concerned, it has been generally recognized that the post-war period has been an era of unprecedented economic expansion for the world as a whole as well as for the majority of both developed and developing countries.<sup>185</sup> It has also been noted that although there has been much discussion of the widening gap between the two regions, it is often overlooked that total production in the developing countries as a whole increased at about the same rate as that of the more developed countries as a group. Both industrial and agricultural output in the less developed countries, it is asserted, expanded at about the same rate as in the more advanced countries.<sup>186</sup> However, when population growth is taken into account and progress is measured in terms of *per capita* income, the deterioration of the position of the less developed countries vis-à-vis the more developed ones becomes evident. According to estimates cited earlier in this section, it appears that, between 1950 and 1967, total output in the developing and developed market economies increased at a very similar rate of around 4.5 per cent annually and that, in fact, it may have been somewhat higher in the former. However, since the population of the less developed countries increased on the average by 2.2 per cent annually during this period compared with only 1.2 per cent in the developed countries, *per capita* income rose by 3.2 per cent annually in the latter, but by approximately 2.4 per cent in the less developed.<sup>187</sup> Thus, although in historical perspective, total output and even *per capita* income increased rapidly in the less advanced countries, their relative position with regard to the more advanced countries deteriorated considerably. Present patterns of population growth, as has been observed, thus have increased the existing imbalance between the distribution of the world's population and wealth.<sup>188</sup>

86. The divergence between the population growth rates of the two principal world segments naturally affects their relative share of world population. According to the United Nations estimates, the percentage of the total population of the world living in the less developed regions increased from somewhat less than 64 per cent in 1920 to an estimated 70 per cent in 1970, with the largest increases occurring since the 1950s. The share of the more developed countries decreased accordingly from

TABLE XIV. 7. DISTRIBUTION OF WORLD POPULATION BETWEEN MORE DEVELOPED AND LESS DEVELOPED REGIONS, 1920-1960

Year	Percentage of total population	
	More developed regions	Less developed regions
1920 .....	36.2	63.8
1930 .....	36.7	63.3
1940 .....	35.8	64.2
1950 .....	34.5	65.5
1960 .....	32.1	67.9

<sup>a</sup> Projected.

somewhat over 36 to 30 per cent (table XIV.7). The combination of a slower rise in *per capita* income and a more rapid increase of population in the developing countries has thus had, as a result, an increased impoverishment of the world's population in the sense that both the share of the poorer countries' population in the world's total increased and their relative income in comparison with that of the more developed countries declined. According to estimates of the distribution of the world's population and income prepared by Kuznets and Deane, the share of the population of the less developed regions of Africa, Asia and Latin America in the world total increased from somewhat more than 66 per cent in 1938 to over 71 per cent in 1961, whereas the share in the world's income of these regions went down from nearly 24 per cent to less than 20 per cent during the same period<sup>189</sup> (table XIV.8).

87. Estimates of income and population for some seventy countries in the early post-war period.<sup>190</sup> have been used for determining the percentage distribution of income and population according to *per capita* income groups<sup>191</sup> (table XIV.9). The data indicate that whereas more than half of the population included lived in countries having a *per capita* income of less than 100 dollars and received only some 9 per cent of the total income, the one third of the population in countries with *per capita* income of 200 dollars or more accounted for some 85 per cent of the total income of the seventy countries. More recent estimates for 1965, although not completely comparable with the former ones, suggest that a further relative

deterioration may have taken place in the position of the group of lower income countries<sup>192</sup> (table XIV.10). According to these estimates, 53 per cent of the world's population with a *per capita* product of up to 125 dollars received less than 8 per cent of the world's gross domestic product. At the other extreme, the 28 per cent of the world's population with a *per capita* product of 751 dollars or more accounted for 81 per cent of the world's total product.

<sup>192</sup> Hagen and Hawrylyshyn, "Analysis of world income and growth..." (1969). The writers, however, also draw attention to the limitations of these income data.

88. Estimates of the distribution of world gross domestic product and population and of absolute and relative levels of product per head in different regions in 1958 were prepared by Kuznets. They revealed large inequalities in the distribution of world product and population between the more developed and less developed regions.<sup>193</sup> Estimates for 1960, compiled by Zimmerman, suggested similar conclusions.<sup>194</sup> More recent estimates, for 1967,

<sup>193</sup> Kuznets, *Modern Economic Growth*... (1966), table 7.1, pp. 360-363. For estimates of net domestic product by regions in 1955, see Kristensen *et al.*, *The Economic World Balance* (1960), table VII.2, p. 250.

SOURCES: Gross domestic product: data from United Nations, *World Economic Survey, 1969-1970* ... (1971), table A.1, pp. 177-179, except for China, the Democratic People's Republic of Korea and the Democratic Republic of Viet-Nam. Total gross domestic product for these countries was calculated from population data and estimates of the gross domestic product per head for 1965 in Hagen and Hawrylyshyn, "Analysis of world income and growth ..." (1969). Population data from United Nations, *Demographic Yearbook, 1969* ... (1970), table 4, pp. 136-143.

<sup>a</sup> Not shown separately.

<sup>b</sup> Includes: Mongolia, the Democratic People's Republic of Korea and the Democratic Republic of Viet-Nam.

which cover most countries of the world<sup>195</sup> and which are not completely comparable with Kuznets's estimates, suggest the same conclusions (table XIV.11). According to these estimates the less developed countries—both market economies and centrally planned economies—accounted for more than two thirds of the world's population, but for less than 15 per cent of the total product. The developing market economies, with a population representing 46 per cent of the total, produced only 12 per cent of the total gross domestic product. The Asian centrally planned economies with a population representing 22 per cent of the total accounted for only 3 per cent of the product.

89. Even though the estimates cited may be subject to a considerable margin of error and may have underestimated in particular the levels of production and income in the less developed countries, they confirm the trend towards a relative spread of under-development. Population in the less developed regions has increased during the post-war period at a much more rapid rate than in the economically more advanced countries. Growth of product and income in the former, however, has been lower or has barely kept up with the increase in the more developed regions. An increasing portion of the world's population is thus living in areas where incomes and levels of living are low and have remained so in comparison with those in the economically more developed countries.

<sup>195</sup> The total population of the countries included represented nearly 99 per cent of the estimated world population in 1967.

## (b) Levels and growth of income and population

### (i) Global trends

90. The observed recent trends in growth of population, total product and *per capita* income in the more developed and less developed countries suggest a number of possible associations and interrelations. One of the most evident among these is the inverse relation between population growth and levels of *per capita* income. As discussed earlier, this negative association emerged in the 1930s, when the growth of population in the less developed countries began to surpass that in the more developed countries. Income data and estimates of population growth, classified according to growth types, for fifty-three countries in 1939, cited by Bonné, provide evidence that already at that time population growth was inversely related to *per capita* income. In particular, all countries with a high potential growth of population had *per capita* incomes of less than 100 dollars<sup>196</sup> (see table XIV.12).

91. Data for the post-war period confirm the existence of such a negative association.<sup>197</sup> Estimates for the late 1950s brought together by Kuznets showed large differences in population growth between more developed and less developed countries. Rates of natural increase of

culated from United Nations, *Demographic Yearbook, 1969 ...* (1970), table 4, pp. 136-143.

<sup>a</sup> Weighted by the size of the population of each country in the same income group.

population in eighty-eight countries, when classified according to *per capita* gross domestic product revealed a marked population growth differential between countries with a *per capita* product below or over 400 dollars (see table XIV.13). In the different income groups below the level of 400 dollars, average annual growth rates, unweighted or weighted, were all well over 20 per thousand, the lowest average rate being 21.6 per thousand. In contrast, in countries with a *per capita* product of 400 dollars or over, average annual rates of growth, unweighted or weighted, for each income group were below 20 per thousand, and in all income groups but one the average

was below 15 per thousand. If it may be assumed that at that time a *per capita* product of 400 dollars constituted an approximate dividing line between developed and developing countries, these estimates thus confirm the generally observed negative relation between population growth and level of development. At the same time, if rates of growth within each of the two broad groups of countries with *per capita* product below 400 dollars and above 400 dollars are compared, little if any association appears to exist between population growth and level of income. Only in the case of the unweighted averages for countries with a *per capita* product of 400 dollars or

over do rates of population growth vary inversely with the *per capita* product. It is doubtful whether this association is significant, however, since the weighted averages of population growth in this group of countries suggest a positive relation between the increase of population and *per capita* product as do the unweighted averages for the different income classes below 400 dollars.

92. The distribution of countries according to estimated rates of population growth and of *per capita* product for 1967, shown in table XIV.14, support, in general, the earlier findings of significant differences in rates of population growth between more developed and less developed countries. The distribution of rates of growth within each income class<sup>198</sup> and the corresponding averages for countries and areas with *per capita* product below 400 dollars contrast sharply with the distribution and averages of population growth rates in those with incomes of 700 dollars and over. In the latter group, nearly nine tenths of the countries had population growth rates below 2 per cent per annum; conversely, growth rates were 2 per cent or over in more than nine tenths of the countries with *per capita* product below 400 dollars. The distribution of growth rates in the intermediate class—with *per capita* products varying between 400 and 699 dollars—is less

clear. Both unweighted and weighted average rates of natural increase for this group are high. But it includes besides a number of rapidly developing countries with comparatively high levels of *per capita* product and rapidly growing populations—such as Hong Kong, Mexico and Panama—also various countries—such as Argentina, Portugal and Yugoslavia—with low population growth, but a relatively low level of *per capita* product in comparison with other countries of low population growth.

93. Despite the close and inverse relation between levels of *per capita* income and growth of population and the considerably more rapid increase of population in the developing countries, no relation appears to exist between growth of population and growth of total product. As has been noted in preceding subsections, during the post-war period the growth of product was similar in the more developed and less developed countries. The lack of any distinct pattern in this respect is suggested by data on the growth of income discussed earlier in this section. It is also illustrated by estimates for the period 1955 to 1965 when the developing countries registered an over-all growth of product appreciably higher than that of the developed countries, but their relative gains occurred all during the latter part of the 1950s. In the first half of 1960 the growth of gross domestic product in these countries slowed down, while that of the more developed countries accelerated and surpassed that of the former group.<sup>199</sup>

94. A comparison of growth of population and total product in sixty-one non-socialist countries between the early 1950s and 1964, made by Kuznets, confirms the

<sup>198</sup> The grouping of countries in classes of *per capita* gross domestic product has been done in such a manner that the variations of average rates of growth for subdivisions within each class would be small. For instance, the unweighted average rate of population growth for countries with *per capita* products between 400 and 499 dollars was 22.9 per thousand; 22.5 per thousand for countries with products per head between 500 and 599 dollars and 21.2 per thousand for those with incomes between 600 and 699 dollars. For the income class from 300 to 399 dollars *per capita*, the unweighted average was, as can be seen from the table, 29.4 per thousand, while for countries with *per capita* products between 700 and 799 dollars it was 15.9 per thousand.

<sup>a</sup> Compound rate between terminal years, based on gross domestic product at market prices, except in the case of centrally planned economies where the basis is net material product at market prices.

<sup>b</sup> Weighted by the size of the population of each country in the same income group.

lack of any significant relationship between the two (table XIV.15). In twenty-one developed countries (including Japan), total product increased by 4.77 per cent annually, while total population increased by only 1.1 per cent. In twenty-one African and Asian countries (excluding Israel and South Africa) total product increased at an average annual rate of 4.95 per cent, but population growth was 2.66 per cent annually, while for nineteen Latin American countries the corresponding rates were 4.86 for total product and 2.61 for population. Despite large differences in population growth between the first group of more developed countries and the two remaining groups of less developed countries, growth rates of total product were very similar. Additional evidence in this respect is provided by data for groupings of individual countries, arranged according to rates of population growth, within the three broad regional groups distinguished (table XIV.15). Within each of these regional groups growth rates of total product are shown to vary in a manner independent of population growth.<sup>200</sup> The lack of a significant relation between growth of population and total product was also suggested by other findings. An analysis of growth rates of population and net national product in a sample of twenty-two countries for the years between 1953 and 1965 revealed that although the relationship between the two was positive, it was not clearly defined and not significant.<sup>201</sup>

95. Data on growth rates of gross domestic product and population for a large number of countries in the period 1960 to 1967 lead to similar conclusions (table XIV.16). The distribution of individual countries according to population growth within each of the levels of growth of product is fairly uniform for all levels. Likewise, average population growth rates for different levels of growth of product vary within comparatively narrow limits in relation to the variation in population growth rates in individual countries. Whereas for individual countries these rates fluctuate from very low, or even

negative values, to close to 4 per cent, the unweighted averages range between only 1.8 to 2.5 per cent and the weighted averages from 1.6 to 2.5 per cent. Even so, the comparatively low weighted averages at the upper level of growth of product—7 per cent and over—suggest that high rates of growth of total gross domestic product may be more common in countries with a lower growth of population.

96. The general finding that no apparent relationship between the growth of product and that of population does exist, in conjunction with the fact that population increases on the average at a much higher rate in the less developed countries, implies a negative association between growth of *per capita* product or income and of population if the two broad groups of more developed and less developed countries are distinguished. Estimated growth rates of population and *per capita* gross domestic product between the early 1950s and 1964 for more developed and less developed regions compiled by Kuznets confirm the existence of a negative association between the two in the two broad groups of countries (see again table XIV.15). In twenty-one non-socialist developed countries an average annual rate of growth of population of 1.1 per cent was accompanied by a growth of over 3.6 per cent in *per capita* product. In contrast, the corresponding averages for population growth in twenty-one African and Asian countries and in nineteen Latin American countries were 2.7 and 2.6 per cent respectively, whereas the growth of *per capita* income in both of these two groups of countries was 2.2 per cent. The Spearman index of rank correlation between growth of population and growth of *per capita* income for sixty-three countries was found to be  $-0.309$ <sup>202</sup> (see table XIV.18).

97. Population and *per capita* product growth rates of individual countries between 1960 and 1967 grouped according to different levels of increase also indicate a general negative association between these two variables (see table XIV.17). Low rates of growth in *per capita* gross domestic product appear to be concentrated in countries

<sup>a</sup> Including Israel and South Africa, which are not included in regional groups.

where population was increasing rapidly and high rates of growth where population growth was slower. Of the seventy countries, out of a total of 122, in which the annual growth of *per capita* product remained below 3 per cent, 51, or about three fourths, had an annual growth of population of 2 per cent or more. In comparison, of the fifty-two countries with a rapid increase in *per capita* product of 3 per cent or more, thirty, or somewhat less than 60 per cent, had a rate of growth of population less than 2 per cent. Both unweighted and weighted average growth rates of population for the different levels of growth in *per capita* product show that, on the whole, population growth is more rapid in those groups of countries where economic growth in terms of *per capita* product is slower. Where the *per capita* product growth rates were below 3 per cent annually, average rates of population growth were, with a single exception, well over 2 per cent. Where *per capita* product increased at an annual rate of 3 per cent or more, population growth remained, again with a single exception, below 2 per cent. Nevertheless, the negative association is much less than perfect, and the results suggest primarily the contrast between the more developed countries, on the one hand, with higher growth of *per capita* income and a slow or moderate increase in population on the average and, on

the other hand, the predominantly less developed countries where, on the whole, population increased rapidly but *per capita* income growth was relatively slow.

98. Even this broad negative association has a much less than universal applicability. As far as individual countries are concerned, it has been noted that high growth of *per capita* product or income was accompanied in a number of cases by high rates of population growth and that low rates of growth of product or income per head went together in various instances with low population growth.<sup>203</sup> Kuznets calculated correlation coefficients between estimated growth rates of population and *per capita* product for a large number of countries and different regional groupings of them (see table XIV.18). The Spearman index of rank correlation for all sixty-three countries considered, which, as noted before, was -0.309, reflected, according to Kuznets, mainly the difference between more developed and less developed regions. Correlation coefficients for the different regions did not confirm the existence of such a negative association. Although an inverse relation was found for twenty-

<sup>203</sup> Kuznets, "Population and economic growth" (1967); Easterlin, "Effects of population growth ..." (1967). See also Raulet, "Family planning and population control ..." (1970).

one developed countries it resulted, Kuznets asserted, from different economic growth trends within this group not related to population.<sup>204</sup> The indices of rank correlations for twenty-one African and Asian countries, for nineteen Latin American countries and for these 40 predominantly less developed countries combined were all found to be positive, but small and insignificant<sup>205</sup> (see table XIV.18). Easterlin compiled estimates of *per capita* income and population growth in a number of developing countries, but speculated also on the over-all relationship between the two, the growth of population and *per capita* income. He believed that if data on the recent experience of the more developed and less developed countries were combined, higher rates of growth of *per capita* income would tend to be associated with lower population growth rates, although for the less developed countries by themselves no significant positive or negative association appeared to exist.<sup>206</sup>

99. In general the available findings, although too few and not exhaustive or sufficiently representative to permit any firm conclusions, suggest certain tentative inferences. Rates of growth of total product during the post-war period were in historical perspective high in both the more developed and less developed parts of the world. Thus, it has been observed, the capacity for growth of total product was well above that of population, even in the less developed countries where the latter was growing rapidly. Accelerated population growth, it is thus held, has not precluded growth of *per capita* income in these countries.<sup>207</sup> However, to the extent that rates of growth of total product or income were similar in both more developed and less developed countries, but population increased faster in the latter group, levels and growth of *per capita* income tended to be negatively associated with population growth.

100. This negative relationship appears to hold only when the experience of the more developed countries is contrasted with that of the less developed ones and even then the correlation is relatively weak. In the case of more developed and less developed regions taken separately, no significant association appears to have existed, a conclusion which seems also to be supported by the experience of a number of individual countries. Fundamentally, these findings based on the post-war trends are similar to those reached with respect to long-term trends, discussed in the preceding section. As noted there, given the great number of and variations in determinants of population and economic growth, the interrelations

between the two as they manifest themselves in practice are diverse and do not conform to one single pattern.<sup>208</sup>

## (ii) *The more developed countries*

101. Post-war economic growth in the more developed countries is generally recognized to have been very rapid.<sup>209</sup> This recent acceleration was in sharp contrast with developments during the inter-war period. Whereas prior to the First World War the Western European countries had experienced a considerable growth of population, high rates of capital formation and a rapid growth of output, the period after the First World War witnessed only a slow increase of output with interruptions and setbacks caused by the Depression.<sup>210</sup> Since the Second World War, however, economic growth has speeded up, in many cases to levels unprecedented in earlier history. Although these post-war economic trends in the more developed countries have been studied in considerable detail, comparatively little attention has been given to the interrelations between economic and population growth during this period.

102. Post-war trends contrasted sharply with the previous period. Economic trends in the inter-war period have been extensively analysed by Svernilson, who attributed the slow economic growth during this time to a great extent to the lack of transformation of the European economy. Among the factors responsible for the absence of a sufficiently strong transformation necessary to adjust to the changed conditions after the First World War, he listed the shift in patterns of population growth. On the whole, he asserted, Europe's population expanded rapidly during that period, but the centre of demographic growth moved from the Western, more industrialized countries, where growth was slowing down, to the Southern and Eastern European countries. Arguing in the tradition of the stagnation theory, Svernilson held that the retardation of population growth in most of the western countries, accompanied by a slow growth or stagnation of many large cities, may have had a depressing effect on the expansion of employment and economic growth. In contrast, in Southern and Eastern Europe, the acceleration of population growth, as a result of declining mortality and the closing of immigration outlets overseas, was accompanied by a lagging industrialization. The consequent failure to increase employment opportunities rapidly enough in the non-agricultural sectors created widespread employment problems, including those in the agricultural sector where a pressure on agricultural resources already existed. These regional disequilibria within Europe could have been solved, according to Svernilson, by the transfer of capital from the more

<sup>204</sup> See section C.2 (b) (ii) below.

<sup>205</sup> Kuznets, "Population and economic growth" (1967). The estimates used referred to non-socialist countries only. Kuznets thought that even if the latter were to be added and if data over a longer period were to be available, the lack of any significant association between population and *per capita* income growth would still hold true. For a more recent comparison for twenty more developed market economies and thirty-five developing market economies which led to a similar conclusion, see Sauvy, "Les charges économiques ..." (1972).

developed western parts to the countries of Southern or Eastern Europe or by migration of labour from the latter to the countries in the west where labour supply was scarce.<sup>211</sup>

103. The Second World War is generally thought to have had a considerable effect on economic growth and a smaller, though significant effect on population during the war period itself and for a number of years thereafter.<sup>212</sup> Rapid post-war economic growth in these countries, although involving an element of recovery, has been accompanied by population growth at a level well above that of the previous decades, but it is not clear to what extent the two were interrelated. In general terms, it has been speculated that in highly developed economies a substantial rate of population growth, acting as an autonomous factor, stimulating demand, accompanied by a rapid increase in the working population which facilitates the expansion and flexibility of employment, might be conducive to economic growth.<sup>213</sup>

104. Indications whether substantial population growth may have facilitated the growth of output were found to be inconclusive in a United Nations study on economic growth in Europe and North America during the 1950s. A comparison of rates of increase of total and *per capita* gross domestic product revealed a significantly different ranking of some countries for each of the two indices, which suggested the existence of some association between the rates of growth of total product and population, but the evidence was far from conclusive. With regard to the Eastern European countries and the Soviet Union, it was noted that, except for Bulgaria, the estimates of growth of net material product and population growth also pointed to some, but not very strong, association between the two. However, such an association, it was noted, did not necessarily imply in the case of the latter group of countries a direct relation between growth of population and that of product; it may have been the result of a negative correlation between population growth and the level of development of a country and, as at lower levels of development economic growth can be much more rapid, a positive one between the level of development and the rate of economic growth.<sup>214</sup>

105. The same study discusses in more detail the relations between the growth of labour force and that of total product and productivity. Data for twenty-two countries, including Turkey and Yugoslavia, revealed a marked, although far from perfect, positive association between the rates of growth of gross domestic product

and of the labour force.<sup>215</sup> The existence of a positive association was, however, less clear in the case of thirteen more industrialized countries.<sup>216</sup> Estimates of the rates of growth of labour supply in productive sectors and net material product in five centrally planned economies did not show a clear association, although it was held that, in general, the rates for these countries were such that they would tend to strengthen the broad association found in the twenty-two countries.<sup>217</sup> An analysis of growth in output, productive capacity and labour force in twelve developed countries during the period 1950 to 1958 also suggested the conclusion that the rate of expansion of the labour force seemingly contributed to differences in growth of output, although the relation between growth of product and labour force was clearest when countries at the extremes were considered.<sup>218</sup> The results of the earlier study cited also suggested the possible existence of a positive association between labour force and productivity growth. Higher rates of increase of the labour force were accompanied by still higher rates of growth of total gross domestic product, implying thus a tendency for high rates of growth of working population to be associated with higher output per worker.<sup>219</sup>

106. The importance of the rate of growth of the labour force for post-war economic growth in Europe was stressed by Kindleberger. Using a modified version of the model of unlimited supplies of labour developed by Lewis, he held that a large supply of labour, resulting from rapid increase of population, the transfer of workers out of agriculture or immigration, was a major factor in growth trends in different countries. Economic growth slowed down, he argued, when the abundant supply of labour no longer existed.<sup>220</sup> Although this view has found little support in other comparative studies of economic growth in Europe during the post-war period,<sup>221</sup> the slow increase in labour force was one of the principal constraints on planning objectives in both the market and centrally planned economies of Europe.<sup>222</sup>

107. In general, it appears that a weak, but far from significant association may have existed between population and total income growth in the more developed countries during the post-war period, but there is little

<sup>211</sup> Svernillson, *Growth and Stagnation* ... (1954), pp. 20, 43 ff., 62 ff. For a discussion of the pressure of population on resources and estimates of the extent of underemployment in Eastern and Southern Europe, see also Moore, *Economic Demography* ... (1945); Mandelbaum, *The Industrialization of Backward Areas* (1961).

<sup>212</sup> See, for instance, Kuznets, *Postwar Economic Growth* (1964), pp. 70 ff., and on the effect of the war on growth in the years following it; also Maddison, *Economic Progress and Policy* ... (1970), pp. 30 ff.; Lamfalussy, *The United Kingdom* ... (1963), pp. 12 ff.

<sup>213</sup> United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1961*, part II ... (1964), chap. 2, p. 2.

<sup>214</sup> United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1961*, part II ... (1964), chap. 2, pp. 2, 8.

<sup>215</sup> The simple correlation coefficient between growth of product and labour force was 0.71. Multiple correlation analysis, including also the rates of increase of fixed capital investment, gave a partial correlation coefficient of 0.70, with the rate of labour force growth explaining about half of the variations in the growth rates of output.

<sup>216</sup> The simple correlation coefficient in this case was 0.47; but the partial correlation coefficient, when also investment was considered, was very low.

evidence, if any, of an association between population growth and growth in *per capita* income. This is confirmed by Kuznets's findings mentioned before. He found a negative index of rank correlation at  $-0.434$  between growth of population and *per capita* product in twenty-one more developed non-socialist countries (including Japan). This association, he noted, reflected, however, mainly differences between the European countries and Japan, on the one hand, and the areas of European overseas settlement, on the other. In the latter, population increased relatively rapidly, partly as a consequence of immigration, but *per capita* product expanded, due to factors not related to population, at lower rates. Exclusion of these countries—Canada, United States of America, Australia and New Zealand—reduced the index of rank correlation to only  $0.06$ <sup>223</sup> (see table XIV.19). On the basis of data for 1959-1969 for 20 more developed market economies, Sauvy found a negative correlation between growth of population and *per capita* product, but a positive one when countries with rapid population growth were excluded.<sup>224</sup>

### (iii) The developing countries

108. As in the case of the more developed countries, large differences exist between the less developed regions and countries with respect to past and present levels and rates of growth of income and the size and increase of population. Moreover, these differences date back a long time. According to crude estimates, at the outset of the First World War *per capita* income, in prices of 1953, was about \$170 in Latin America; \$90 in the Far Eastern countries; somewhat over \$60 in South-East Asia and

about \$50 in China.<sup>225</sup> Levels of income in Africa were probably at that time not much above the figure cited for China.<sup>226</sup> As noted before,<sup>227</sup> significant increases in the levels of living between the First and Second World War were in all likelihood limited to Latin America, while in the other developing regions estimated income levels increased only slowly or not at all. It has also been shown that population growth rates in the predominantly less developed regions varied considerably in the past, with higher growth rates found especially in Latin America.<sup>228</sup>

109. Post-war trends in total income and population in the different less developed regions have probably tended to a greater extent than before towards convergence. As far as trends in total product are considered, estimated rates of growth for each of the major less developed regions appear to have diverged only comparatively little from their average. According to one set of estimates for 1950 to 1960, the gross product of the developing market economies increased at an average annual rate of growth of 4.4 per cent compared with regional growth rates of 4.6 per cent for Latin America, 4.2 per cent for the Far East (excluding Japan) and 4.1 per cent for Africa.<sup>229</sup> Estimates for the period 1955 to 1965 indicate that while the over-all growth rate of the gross domestic product for all developing market economies included was 4.5 per cent annually, those of the major regions varied from 3.9 per cent in Southern and South-East Asia to 4.4 per cent in Africa and 4.5 per cent in Latin America.<sup>230</sup>

<sup>226</sup> It was speculated that in Africa *per capita* income (in 1960 prices) a century ago may have been of the order of \$45. See United Nations, Economic Commission for Africa, *Survey of Economic Conditions in Africa*, 1968 (1972), p. 6.

<sup>227</sup> See section B of this chapter.

<sup>228</sup> See chapter II, table II.8.

<sup>229</sup> United Nations, *World Economic Survey*, 1963. I... (1964), table 2.1, p. 19. It must be remembered, however, that these estimates are subject to a considerable margin of error. Nevertheless, they appear to be generally consistent with other estimates for the same period or subperiods thereof. For Asia, other estimates are consistent with those cited here. See, for instance, United Nations, Economic Commission for Asia and the Far East, *Economic Survey of Asia and the Far East*, 1969 (1970), table 1, p. 4, and *Economic Survey of Asia and the Far East*, 1970 (1971), table II.1.3, p. 95. The estimates cited for Latin America may have been somewhat low—see United Nations, Economic Commission for Latin America, *Economic Survey of Latin America*, 1965 (1967), table 1, p. 1. Estimates for Africa show, in general, a much wider range of variation than for the other regions. See, for instance, United Nations, Economic Commission for Africa, *A Survey of Economic Conditions in Africa, 1960-1964* (1968), table 3, p. 21, for estimates for the period 1955 to 1960, which are well below the estimates for that period in the main source cited above.

<sup>230</sup> United Nations, *World Economic Survey*, 1967, part I... (1968), table 2, p. 17. The estimate for the Asian region of developing market economies appears to be generally consistent with other estimates for that period. United Nations, Economic Commission for Asia and the Far East, *Economic Survey of Asia and the Far East*, 1966 (1967), table II.1.1, p. 100, gives a higher estimate for the period 1960 to 1965 than the one in the source cited here. The estimate for Latin America conforms to those from other sources. See, for instance, United Nations, Economic Commission for Latin America, *Economic Survey of Latin America*, 1965 (1967), table 1, p. 1; Hagen and Hawrylyshyn, "Analysis of world income and growth..." (1969). This latter study, however, gives estimates

<sup>223</sup> Kuznets, "Population and economic growth" (1967).

<sup>224</sup> Sauvy, "Les charges économiques..." (1972).

110. Population growth in the major developing regions in the post-war period exhibited a marked tendency towards greater uniformity. The rate of increase of population in Latin America, which traditionally had been higher than in other regions, had already attained a very high level early in the post-war years and remained at about 2.8 per cent annually during the 1950s and 1960s. In both Africa and South Asia population growth had already accelerated to about 2 per cent annually between 1950 and 1955 but speeded up further during 1965-1970 to reach an estimated 2.6 per cent in the former and 2.8 per cent in the latter.<sup>231</sup>

111. Estimated rates of growth of *per capita* product in the major developing regions were fairly uniform during the 1950s. According to one source of estimates, between 1950 and 1960 *per capita* product increased by 1.8 per cent annually in Latin America, by 1.9 per cent in Africa and by 2.1 per cent in the Far East.<sup>232</sup> While the same rate of increase in *per capita* product as in 1950 to 1960 prevailed during 1955 to 1965 in Latin America, in Africa the growth of *per capita* product was estimated to have accelerated in the latter period to 2.2 per cent annually. In contrast, in South and South-East Asia progress was slower, as *per capita* product increased at a rate of only 1.6 per cent.<sup>233</sup> Post-war trends, however, have contributed little to the narrowing of the gap in income levels between Latin America, on the one hand, and the developing countries of Africa and Asia, on the other. In absolute terms the differences increased and in 1967 the *per capita* product in Latin America was estimated to have been, as noted before, of the order of 450 dollars compared with figures of around 130 dollars in Africa and Asia (excluding Japan and the centrally planned economies).<sup>234</sup>

112. In general, little is known concerning the interrelations between population and economic growth in these different regions. With respect to Africa, a United Nations study, for instance, observed that it was not possible to determine to what extent the slow growth of income and the failure of African economies to expand at a high enough rate was the result of the rapid increase of population. It was argued, however, that although there might be certain seeming advantages from a larger population, other demographic characteristics of the African population might have an adverse effect on

economic growth. Population growth, it was recognized, could bring about a more favourable population-resources ratio in view of the over-all low density. Any conceivable advantages of a rapidly growing population, it is further asserted, are counteracted by the high dependency ratio, with the consequent lower income per person for a given product per worker and the higher outlays needed for education, and so forth. The comparatively still high death rates, and especially the high infant mortality, it is further argued, means that a substantial proportion of the resources used in raising and educating children is lost before they make a significant contribution to income. On the whole, the study concluded that although in many African countries a larger and better distributed population may be a condition for development over a long period, in the short run a high rate of population growth is likely to be an obstacle to rapid economic evolution.<sup>235</sup> While the lack of sufficient data precludes a detailed analysis of the interrelationships, there are some indications, it is asserted, that in recent periods rapid population growth may have had an adverse effect on growth in *per capita* product. Data on population growth and the rate of increase of *per capita* income in thirty-five African countries between 1960 and 1966 revealed that of the ten of these countries where population increased at a rate of less than 1.9 per cent annually, only two experienced a decline in *per capita* product while the remaining eight had increases of between 1.4 to 1.7 per cent annually. In contrast, of the twenty-five countries where population increased at an annual rate of 1.9 per cent or more, eleven had negative rates of growth of *per capita* product, *per capita* product increased less than 1 per cent annually in seven, and in the remaining seven the rate of growth of *per capita* product varied between 1.6 and 3.2 per cent annually.<sup>236</sup>

113. Economic growth in the developing market economies of Asia during the war period and the first post-war years is thought to have been slow partly as a result of the dislocations and destruction caused by war. Although the rate of economic development since then has been considerably faster than before the war in the majority of countries, it has been noted that the acceleration of growth during the post-war period made for only limited gains in *per capita* income. Although the growth in total product of the region in the 1950s was estimated to have been higher than in the developed market economies as a whole, its *per capita* product increased more slowly than that of the developed market economies due to higher population growth.<sup>237</sup> Despite a further accel-

lower than the one cited for Africa. Earlier estimates for the latter five years of the period 1955 to 1965 were below those from the primary source cited here. See, for instance, United Nations, Economic Commission for Africa, *A Survey of Economic Conditions in Africa, 1967* (1969), tables 1 and 3, pp. 1-3. Recent estimates suggest rather a faster growth. See United Nations, Economic Commission for Africa, *A Survey of Economic Conditions in Africa, 1969*, part I (1971), table 3, p. 8, and *Survey of Economic Conditions in Africa, 1970*, part I (1971), table 2.1, p. 21.

<sup>231</sup> United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication). However, population growth in East Asia, which includes China and Japan, remained moderate and stable at a level of about 1.8 per cent annually in the two most recent decades.

<sup>232</sup> United Nations, *World Economic Survey, 1963*. I. ... (1964), table 2.3, p. 21.

<sup>233</sup> United Nations, *World Economic Survey, 1967*, part I ... (1968), table 2, p. 17.

<sup>234</sup> See table XIV.12.

<sup>235</sup> United Nations, Economic Commission for Africa, *A Survey of Economic Conditions in Africa, 1960-1964* (1968), pp. 2, 46-58.

<sup>236</sup> United Nations, Economic Commission for Africa, *A Survey of Economic Conditions in Africa, 1967* (1969), pp. viii-ix. Also United Nations, Economic Commission for Africa, *A Survey of Economic Conditions in Africa, 1969*, part I (1971), pp. 89-90.

<sup>237</sup> United Nations, Economic Commission for Asia and the Far East, *Economic Survey of Asia and the Far East, 1965* (1966), pp. 155-156. It has been pointed out that the population censuses taken around 1960 revealed that in a number of countries previous population estimates had been too low, so that the real increase in levels of income were much less important than they had appeared to be. See, for instance, United Nations, Economic Commission for Asia and the Far East, *Economic Survey of Asia and the Far East, 1961* (1962), pp. 3, 119.

ation in the growth of total product during the 1960s, from about 4.0 per cent annually during 1950-1960 to about 4.4 per cent in 1960-1968, the *per capita* product is estimated to have increased at about the same rate as in the 1950s, about 2 per cent annually, due to the fact that population growth accelerated from 2.1 per cent a year in the 1950s to 2.5 per cent in the 1960s. In more general terms, it has been argued that rapid population growth in a number of Asian countries during the post-war period neutralized a considerable part of the growth in total output and held back a more rapid economic development.<sup>238</sup> A lowering of the present high rates of population growth through suitable population policies is seen as an important and urgent need. Even so, it is recognized that measures to control population growth are not a substitute for those aimed at a more rapid increase of output. A reduction in population growth, it is asserted, does not raise output, but only means that with a given growth of production, *per capita* income would increase more rapidly than if population had continued to grow at its earlier higher rate.<sup>239</sup>

114. With respect to Latin America, it has been noted that while total and *per capita* product during the early post-war period increased rapidly, subsequent gains were less as the annual rate of growth of total product slowed down and that of population accelerated due to the fall in death rates.<sup>240</sup> Although between 1950 and the late 1960s total and *per capita* product improved considerably in absolute terms, the latter having been estimated at 355 dollars in 1950 and over 500 dollars towards the end of the 1960s, annual rates of growth in *per capita* product, it is asserted, were only modest. The consequent relative drop in the region's share of the total world product was, at least, in part attributed to the high rates of population growth.<sup>241</sup> Apart from the acceleration of the rate of growth of population in Latin America and its effects on levels of *per capita* income and its distribution, the high rate of increase of the labour force and the problems connected with the limited capacity of the economy to absorb the supply of labour has received special attention.<sup>242</sup> Not only did economic growth proceed at a relatively slow pace, but a considerable proportion of the increase in the economically active population could not be absorbed in an efficient manner into the production process.<sup>243</sup> Considering that modern industrial activities require relatively little labour, an economic growth rate

of 4 to 5 per cent, it is asserted, is insufficient to absorb the labour force when, as in the case of many Latin American countries, population is increasing at a rate of 3 per cent annually.<sup>244</sup> Employment problems in the region intensified during the decade of the 1960s when the labour force is estimated to have increased by 30 per cent while the absorption rate during this period apparently declined. With this relative decline in absorptive capacity has come increased levels of unemployment and underemployment and the spread of marginality, especially in the urban areas.<sup>245</sup> It was estimated that by the end of the 1960s some two fifths of the labour force was underemployed, overtly unemployed, or employed in services which could be regarded as unproductive. It is considered that this problem is likely to become more urgent and create serious social tensions and distortions unless economic growth speeds up significantly.<sup>246</sup>

115. Over-all and regional trends in population and levels of product in the developing world do not reflect the wide variations of growth rates and levels of income in individual countries. Estimated rates of increase of gross domestic product and of population in sixty-three developing market economies between 1955 and 1965 convey an idea of the large differences which exist within the group of developing countries both with respect to increase of income and of population (table XIV.19). Data on *per capita* product and population in sixty-seven developing market economies in 1965 illustrate the large disparities in current levels of living<sup>247</sup> (table XIV.20). Although these distributions show primarily the wide variety of conditions in the developing world, a comparison of the percentage distribution of countries with the percentage distribution of their populations reveals a

SOURCE: Easterlin, "Effects of population growth ..." (1967).

marked asymmetry both for the growth rates of total output and levels of *per capita* income. Thus, one fourth of the countries had a *per capita* product of less than 100 dollars in 1965, but their population accounted for nearly two thirds of the total population. At the other extreme, also, about one fourth of the countries had a *per capita* product of 301 dollars or more, but their combined population was less than one tenth of the total (see again table XIV.20). These results indicate not only that levels of living in these economies were, on the average, considerably lower than might be inferred from the distribution of countries, but also that the countries which are relatively better off are predominantly the smaller ones in terms of population, while the larger countries are, on the whole, the poorer ones. The data on the growth of total product (table XIV.19) show the same asymmetry between the distributions of countries and of their population and suggest that these divergencies are increasing. While one third of the countries for which data were available for 1955 to 1965 achieved growth rates of total product of more than 5 per cent, their population represented only one sixth of the total. In contrast, about one fourth of the countries experienced a growth of total product at a rate of less than 3.5 per cent annually, but their population accounted for nearly half of the total. On the basis of data for 1960 to 1967, it has been noted that most of the high-growth countries had relatively small populations. Further evidence in this respect was revealed by a comparison with more developed countries: whereas 45 per cent of the population of this group was in countries in the upper quartile of growth rates (with output increasing 6.6 per cent or more annually), only 10 per cent of the population of the developing countries was found to be in the corresponding upper quartile (with output increasing at 6.7 per cent or more a year). At the other extreme, the proportion of population in the developing countries that was in the lower quartile of growth rates (with output increasing annually at 2.7 per cent or less) was 18 per cent, as compared with 9 per cent in the lower quartile in the more developed countries (with output increasing 4.0 per cent or less annually).<sup>248</sup>

116. Although the discussion of regional trends suggests that under given conditions a lower rate of population growth in most developing countries would help

their economic development, actual growth trends in developing countries do not provide evidence of a significant and systematic association between the two within the developing countries. Comparisons of rates of population growth in low income countries with levels of *per capita* income (tables XIV.13 and XIV.14) and with rates of growth of total and *per capita* product (tables XIV.15 to XIV.17) did not, as noted before, reveal the existence of such an association. As discussed earlier, the index of rank correlation between growth of population and *per capita* product for forty developing countries, obtained by Kuznets, was positive, but low and not significant (0.111). For twenty-one developing African and Asian countries, the index of rank correlation was also low (0.079) and for nineteen Latin American countries it was higher (0.246), but not significant (table XIV.18). Whereas the relationship between growth of population and *per capita* income in developing countries is open to different interpretations,<sup>249</sup> a comparison of growth rates of *per capita* income and population made by Easterlin lends support to the earlier conclusion (table XIV.21). Based on data for thirty-seven developing countries, excluding those with populations under 2 million, the results showed, according to Easterlin, that there is little evidence of any significant positive or negative association between the growth rates of *per capita* income and population.<sup>250</sup> Sauvy also found that the correlation coefficient between the growth of population and *per capita* income in thirty-five developing countries during 1959-1969 was low and not significant.<sup>251</sup>

117. Even if there appears to exist no direct and verifiable relation between population and economic growth in the less developed countries, this does not imply that population and economic development are unrelated. It is likely that lower population growth under given conditions would speed up the growth of *per capita* income, if not necessarily that of total product. Moreover, as Kuznets observed, there are other important and desirable aspects of economic growth in addition to income. He

<sup>249</sup> Stockwell, "The relationship between population growth ..." (1962), compared growth rates of population and *per capita* income in 16 developing countries between 1952 and 1958 and found a negative rank correlation coefficient (-0.68). The selected countries considered as less developed included, however, Austria, Greece, Italy and Portugal.

<sup>250</sup> Easterlin, "Effects of population growth ..." (1967).

<sup>251</sup> Sauvy, "Les charges économiques ..." (1972).

<sup>248</sup> United Nations, *World Economic Survey, 1969-1970* ... (1971), pp. 9-10 and table 1.

speculated that even if growth in *per capita* income were not slowed down by a higher population growth, the latter might create other serious problems.<sup>252</sup> Providing the growing labour force with sufficient employment opportunities, achieving a just and equitable distribution of income, and creating acceptable social conditions and opportunities, such as in education, housing and social services, are some development goals which may be seriously hampered by rapid population growth.

(c) *Fertility, mortality and economic development*

118. Underlying the reversal in recent decades of the traditional positive association between the growth of population and levels of income are the changes in the relationship between the main components of population growth, especially mortality, and economic development. Even though mortality differentials between more developed and less developed countries persist, the traditional close association between death rates and levels of development is at present much weaker than it used to be, although with respect to fertility a clear dichotomy between more developed and less developed countries remains.<sup>253</sup>

119. The general fact of the existence of fertility differentials between more developed and less developed countries has been generally recognized. Crude birth rates in the less developed regions in 1965-1970 were estimated to have been about 41 per thousand compared with 19 per thousand in the more developed regions. Corresponding gross reproduction rates were about 2.7 and 1.3, respectively.<sup>254</sup> A United Nations study based on 1960 data revealed also that the distribution of individual countries by levels of crude birth or gross reproduction rates was strikingly bi-modal with a clear distinction between a high fertility and a low fertility group and with few countries on the borderline between them. The dividing line between the two groups of countries could be drawn at a crude birth rate of 30 per thousand population and a gross reproduction rate of 2.0.<sup>255</sup> Birth rates and gross reproduction rates above these levels were nearly all found in the less developed regions of Africa, Asia and Middle and South America, whereas countries with rates below the dividing line were nearly all in the more developed regions. Of the more than eighty countries in the less developed regions (Africa, Asia and Middle and South America) only six had crude birth rates less than 30 per thousand and a gross reproduction rate of less than 2.0. In contrast, only two of the more than thirty countries in the more developed regions (Europe, North America and USSR) had birth rates over 30 per thousand and only three gross reproduction rates of 2 or

more. The exceptions, it was noted, were, in general, countries which, as far as their levels of economic and social development were concerned, were not typical for the regions in which they were located.<sup>256</sup>

120. From these associations it follows that a negative relation may be expected to exist between crude birth rates or gross reproduction rates, on the one hand, and *per capita* income, on the other, for the two broad groups of more developed and less developed countries. The estimates for the late 1950s, shown in table XIV.13, confirm that, on the whole, crude birth rates were significantly higher in those countries where the level of *per capita* income was below 400 dollars. In the latter group of countries, average crude birth rates for different levels of income varied between about 38 to more than 44 per thousand, compared with averages for different income groups above 400 dollars between 21 and 24 per thousand. Similar results emerged when the average crude birth rate for each income class was weighted by the size of the population of each country in the particular class.

121. The distribution of individual countries according to the estimated levels of gross reproduction rates and of *per capita* income in a recent period confirms the earlier finding (table XIV.22). Average gross reproduction rates for all income classes below 700 dollars are all higher than 2.0 and lower than 2.0 for all classes where the *per capita* product is 700 dollars or over. More specifically, no country with a *per capita* gross domestic product under 400 dollars has a gross reproduction rate less than 2.0 and, at the other extreme, only one of the twenty-three countries with a *per capita* product of 1,200 dollars or more has a gross reproduction rate over 2.0 and this, too, is a special case (Libya).<sup>257</sup> The two intermediate income classes include countries with distinctive features. The first of the two—with a *per capita* product varying between 400 and 700 dollars—is dominated by nations with comparatively high or intermediate fertility, but also includes some countries—especially from southern Europe and temperate South America—which have attained low levels of reproduction but whose *per capita* income has remained relatively low. Countries with low fertility predominate among those with a *per capita* product between 700 and 1,200 dollars, but in it are also some countries with special characteristics—such as Namibia, South Africa and Venezuela—with comparatively high levels of income, but gross reproduction rates well over 2.00.

122. The relationships between levels of fertility and several indicators of economic and social development, including the level of income per head, were analysed in the United Nations study cited above.<sup>258</sup> When coun-

<sup>252</sup> Kuznets, "Population and economic growth" (1967).

SOURCES: Data on gross domestic product (except for China) from United Nations, *World Economic Survey, 1969-1970*. . . (1971), table A.1, pp. 177-179. Data for China from Hagen and Hawrylyshyn, "Analysis of world income and growth . . ." (1969); Gross reproduction rates are unpublished United Nations estimates.

<sup>a</sup> Weighted by the size of the population of each country in the same income class.

tries were classified in two broad groups—high fertility and low fertility countries—average values for all economic and social indicators in each of them differed greatly and a high negative association between fertility and economic and social development was found to exist. In the case of *per capita* income, the unweighted average for countries with a gross reproduction rate below 2.0 was 720 dollars compared with 170 dollars for the group of countries with gross reproduction rates of 2.0 or more. The correlation coefficient between the gross reproduction rate and income per head for this two-level classification of fertility was  $-0.60$ . Even so, this correlation coefficient was, on the whole, lower than those between *per capita* income and other economic and social indicators suggesting, according to the study, that the association between gross reproduction rates and *per capita* income may be indirect, operating through other variables.<sup>259</sup>

123. Despite the negative association between fertility and level of development when only two broad groups of countries, more developed and less developed, were distinguished, within each of these groups no clear relationships appear to exist. When instead of two, six different levels of fertility were distinguished, large differences in the average income per head were found only between the gross reproduction rates of the high fertility groups, on the one hand, and of the low fertility groups, on the other, but within each of these two groups correlation coefficients between fertility and income and the other indicators were small (table XIV.23). Among low fertility countries, the correlation coefficients between gross reproduction rates and *per capita* income was low and positive ( $+0.07$ ). Nor was there any clear association between gross reproduction rates and the other economic and social indicators. Within the high fertility countries the correlation coefficient between gross reproduction rates and income per head was negative ( $-0.16$ ). The findings for the high fertility countries suggested, however, that some association may be present in high fertility countries between levels of fertility and economic and

social indicators, taking into account the consistency of the variations in the different indicators which, with few exceptions, are higher the lower the gross reproduction rates.<sup>260</sup>

124. In general, the findings indicating that fertility levels are closely associated with *per capita* income if the economically more advanced and less advanced countries are compared, but not within each of these groups, is confirmed by other data discussed earlier (see table XIV.13). However, the indeterminate nature of the effects which economic variables have statistically on fertility has been emphasized by Kuznets<sup>261</sup> and a number of other studies, which included both more developed and less developed countries, have shown somewhat different results. A multiple regression analysis of fertility in thirty-seven countries, both developed and developing, by Adelman suggested a positive, but weak association between age specific birth rates, especially in the younger reproductive age groups, and levels of *per capita* income.<sup>262</sup> A similar conclusion was reached by Wein-

at birth from United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

<sup>a</sup> Weighted by the size of the population of each country in the same income class.

traub in an analysis for 30 countries, also including both developed and developing countries.<sup>263</sup> Frederiksen, on the basis of a correlation analysis for twenty-one countries, including developed and developing, concluded that while birth rates were strongly associated with other demographic variables, the associations between birth rates and economic variables were only weak.<sup>264</sup> On the whole, it has been suggested, that fertility change and economic and social progress are related processes which, however, are part of a broader process of cultural, institutional and political change in which the weight of purely economic variables may be quite limited.<sup>265</sup>

125. Whereas, traditionally, mortality changes were thought to be dependent upon economic and social change, such an association no longer is evident where recent mortality trends in the presently developing countries are concerned. Large and rapid gains in longevity in these countries have occurred in the absence of significant economic progress and social change.<sup>266</sup> Despite the fact that recent mortality declines have been largely independent of economic development, however, longevity in the economically less advanced countries is still considerably lower than in the more advanced countries. Data for the period 1955-1959 suggested that crude death rates in the less developed regions of Africa, Asia and Latin America were well above or, in the case of the latter, close to the world average of 19 deaths per 1,000 population, while death rates in the more developed

regions were, on the average, considerably lower.<sup>267</sup> For the period 1965-1970, expectation of life at birth was estimated to be 70 years on the average in the more developed countries, as compared with 50 years in the developing regions.<sup>268</sup> Estimated crude death rates in the period 1957 to 1959, classified according to different levels of *per capita* gross domestic product, confirm in general the existence of a significant difference in death rates in countries with high and low incomes (table XIV.13). In the group of countries with *per capita* incomes below 400 dollars, average weighted rates for the different income classes vary from about 14 to 16 per thousand. In comparison, the averages for the different levels of *per capita* income of 400 dollars or more are around 9 per thousand in each of the income classes distinguished. The unweighted averages, however, suggest a less pronounced demarcation between the two groups with a comparatively low average crude death rate for countries with a *per capita* product between 200 and 399 dollars.

126. A comparison of product per head and expectation of life at birth, which, unlike the crude death rate, is not affected by the age composition of the population, for a recent period confirms the existence of a significant positive association between level of development and longevity (table XIV.24). In income classes below 400 dollars by far the largest proportion of countries have life expectancies at birth inferior to 60 years, whereas in the higher income classes the great majority of countries have life expectancies of well over 60 years. Moreover, those countries in the latter group which have comparatively low expectancies are special cases, such as Libya, Namibia and South Africa.

127. Although both unweighted and weighted average life expectancies show the largest difference between the income classes immediately below and over 400 dollars, the data suggest that within each of these two groups of countries and, in general, mortality varies inversely with the level of *per capita* product. Average life expectancies, both weighted and unweighted, increase, although not

<sup>263</sup> Weintraub, "The birth rate and economic development . . ." (1962). The independent variables in the multiple regression analysis were: *per capita* income, the ratio of population in farming and the infant mortality rate. See also on this subject Heer, "Economic development and fertility" (1966) and his "Economic development and the fertility transition" (1968).

<sup>264</sup> Frederiksen, "Dynamic equilibrium . . ." (1966).

<sup>265</sup> United Nations, *Population Bulletin of the United Nations*, No. 7 . . . (1965), pp. 6, 143; Kuznets, "Economic aspects of fertility trends . . ." (1969). For a more detailed discussion of the determinants of fertility see chapter IV. Adelman, "An econometric analysis . . ." (1963) concluded tentatively that the influence of socio-economic variables upon demographic ones is probably much smaller than the effect of population growth upon economic development.

<sup>266</sup> See section B above. Also chapter V, section H.

<sup>267</sup> United Nations, *Population Bulletin of the United Nations*, No. 6 . . . (1963), p. 17.

<sup>268</sup> Chapter V, section A, table V.1.

to the same degree, in all cases when passing from one level of income per head to the next higher one. The presumption of an association between mortality and *per capita* income is supported by an analysis of age-specific death rates in thirty-four countries undertaken by Adelman. Regression coefficients of age-specific death rates upon income were found to be negative for all age groups and statistically significant up to age 50. The elasticity of death rates with respect to income were found, however, to be considerably below unity.<sup>269</sup> In general, these findings thus suggest the continued existence of a significant mortality differential between the economically more advanced and the less advanced countries despite the recent rapid decline of mortality in the latter, although it may be assumed that in view of this process of rapid decline the relation is weakening. The results also indicate a systematic, but probably not very significant, inverse association between mortality and income within the groups of more developed and less developed countries and with respect to individual countries.

(d) *Industrialization, urbanization and economic development*

128. Economic development, industrialization and urbanization are, as has been noted before, linked in a number of ways. Although increases in productivity within each of the sectors, and not the changes in the industrial structure are the main factor in economic growth, and, in principle, industrialization could take place without urbanization, in practice these changes are closely inter-related.<sup>270</sup> From these different associations results a complex of interrelations between economic growth, industrialization and urbanization.

129. Whatever data are available suggest the existence of a consistent relation between levels of economic development, as expressed in an index such as *per capita* income, and the industrial distribution of the labour force. Davis found, for instance, that the average *per capita* income for thirty agricultural countries—defined

as those in which 50 per cent or more of the economically active males were engaged in agriculture—in 1939 was 87 dollars compared with an average of 287 dollars in twenty-two industrial countries.<sup>271</sup> An analysis of data on *per capita* income and the share of agriculture in the labour force in different regions and countries by Bean also led to his conclusion of the existence of a negative association between the two.<sup>272</sup> On the basis of data for forty-three countries, Kuznets found that the proportion of the total working population occupied in the non-agricultural sectors declined from an average of more than 85 per cent for countries with a *per capita* product of 775 dollars or more to one of somewhat over 40 per cent in countries where the product per person was 150 dollars or less.<sup>273</sup> Chenery, using multiple regression analysis, estimated that the proportion of the labour force in primary activities declined from 75 per cent when the *per capita* product was 50 dollars to barely 8 per cent when the *per capita* product increased to 2,000 dollars.<sup>274</sup> In more general terms, a positive association has been found to exist between levels of development and the proportion of the labour force in industrial activities. In 1950, for instance, the more developed countries of Europe, North America and Oceania accounted for 15 per cent of the world's working population, but for 30 per cent of the world's industrial labour force. In contrast, the working population of Asia was estimated to represent half of the world's total, but its industrial labour force was only a quarter of the corresponding total for the whole world.<sup>275</sup>

130. A more detailed study by Kuznets of the industrial distribution of the labour force in fifty-three countries confirmed the existence of an over-all negative association between levels of development, as measured in terms of

<sup>d</sup> Includes transportation and communication; trade; finance; professional, personal and business services and government.

*per capita* product, and the proportion of the labour force in agriculture (table XIV.25). From the results, he inferred that a clear negative correlation existed between differences in *per capita* income and the share of agriculture in the total labour force. The proportion in manufacturing showed a distinct positive correlation with income per head, while a positive, but weaker association appeared also to exist in the case of the services sectors.<sup>276</sup> A more recent study by Kuznets on the basis of similar data also suggested a negative association between the agricultural shares and income and a positive one between the proportions of the labour force in manufacturing and services and *per capita* product.<sup>277</sup>

131. It has been shown earlier in this chapter that significant shifts in the industrial structure of the labour force occur in the course of development. Nevertheless, despite this over-all association between the composition of the labour force and development, considerable variations in the levels, patterns and evolution of the distribution of the labour force among the economic sectors exist in individual cases. The proportions of the labour force in agriculture and other sectors in different countries and within countries varied considerably, Bean noted in a study earlier cited, despite similar levels of development.<sup>278</sup> Kuznets in analysing long-term trends in a number of countries, concluded that changes in the shares of the main sectors over time were far from uniform, especially where the services sector was concerned.<sup>279</sup>

132. The existence of a positive association between the degree of industrialization and the level of urbanization is generally accepted. Davis and Hertz found that the average proportion of the population living in cities of 100,000 or more inhabitants in those countries where more than 50 per cent of the occupied males were engaged in agriculture was only 9 per cent, compared with 27 per cent in countries where less than half of the male working population was occupied in agriculture. When data for 155 countries and territories were classified according to the percentage of active males in agriculture and the percentage of the population in cities of 100,000 and over, a close association between the two was evident (table XIV.26). The correlation coefficient (Pearson) between the degree of industrialization, as measured by the percentage of the male working force in the non-agricultural sectors, and that of urbanization was found to be 0.86.<sup>280</sup> An

analysis by Schnore gave similar results. The correlation between the percentage of active males in non-agricultural activities and the level of urbanization in sixty-nine countries was 0.87 when the latter was defined to include cities of 100,000 and more inhabitants and 0.77 when urbanization was interpreted to include cities of 20,000 or more inhabitants.<sup>281</sup>

133. Estimates of urban population and the industrial distribution of the labour force for individual countries at different levels of development, or at different times, tend to confirm the over-all positive relationship between industrialization and urbanization.<sup>282</sup> Even so, the exact nature of the relation between the two is much less than clear-cut or simple. Significant differences in the industrial structure of the labour force are found between countries with similar levels of urbanization and between the now developing countries and the presently more developed countries in the past at comparable levels of urbanization. The lack of an invariable and functional relation is also implied in the assumption that, in many less developed countries, urbanization is proceeding at an excessive rate compared with industrialization, causing what is often referred to as over-urbanization.<sup>283</sup> Over-urbanization is thought to manifest itself in a number of ways. It may reveal itself in a tendency for urbanization to be much higher than might be expected on the basis of other indicators of development or than could be expected on the basis of the past experience of the presently developed countries, but it may also appear in a disproportionate growth of the urban population in comparison with the expansion of industrial employment or in an excessive increase in service activities.<sup>284</sup> Inferences concerning the existence of over-urbanization have, however, been

questioned. It has been noted that the assumption of a single, well-defined and invariable pattern of industrialization and urbanization is not necessarily justified. Sovani, in particular, has argued that this interrelation may vary according to the level of development. He found that the correlation between the percentage of urban population and that of the labour force in non-agricultural activities in seventeen more developed countries was relatively weak, the correlation coefficient being 0.40. However, for twenty-four other, predominantly less developed countries, the association was strong with a correlation coefficient of 0.87. A high and similar degree of correlation, with a coefficient of 0.84, was also found for thirteen presently developed countries towards the end of the nineteenth century, which led Sovani to conclude that the association between urbanization and industrialization is not stable, but varies for different levels of urbanization and development.<sup>285</sup>

134. The broad associations between development and industrialization, on the one hand, and industrialization and urbanization, on the other, also suggest the existence of a general relationship between the three. Evidence in

this respect is provided by data, compiled by Kuznets, on the shares of non-agricultural sectors in the total labour force and the population in localities of 20,000 inhabitants and over classified according to levels of *per capita* income (table XIV.27). Average shares of non-agricultural activities and of the proportion of town population vary, as the results indicate, positively with the level of *per capita* income.<sup>286</sup> Estimated values of *per capita* income, labour force structure and urbanization based on a multiple regression analysis of data for a large number of countries, presented by Chenery, indicate the extent to which industrialization and urbanization may vary with the level of *per capita* income<sup>287</sup> (table XIV.28). Nevertheless, although the findings establish the existence of an association between these different variables, ratios of the proportion of urban population and the shares of the non-agricultural labour force, calculated by Kuznets, vary in a less than systematic manner, thus indicating that the interrelation is not simple or stable and that patterns of industrialization and urbanization are not necessarily uniform (see again table XIV.28).

#### D. Population and economic growth in the past and present

135. It is a generally accepted fact that the emergence of modern economic growth in the presently more developed countries has been associated with new demographic trends and patterns. There is much less agreement, however, as to the nature of the relationships between population and economic growth during the initial phases of development. According to some authors, population growth was an important factor in setting in motion the process of development; others are of the view that population changes at that time occurred mainly in response to economic and social changes. The historical experience and relations of the presently more developed countries have acquired new relevance in recent decades as the presently developing countries are undergoing a process of rapid economic and demographic change.

##### 1. EARLY MODERN ECONOMIC GROWTH AND POPULATION IN THE PRESENTLY DEVELOPED COUNTRIES

136. The purpose of this section is to attempt to assess in very broad terms the significance of past patterns in the presently more developed nations for the countries now entering into this process. The first subsection presents a brief sketch of economic and population trends during the early phases of modern economic growth in the presently more developed countries. Because of the special significance of England as the first country to experience an industrial revolution, the first part of it is concerned with the role ascribed to population in this process. The second part discusses in more general terms the interrelations between economic and population growth during the initial period in some of the countries which subsequently embarked on the development process. The second subsection summarizes some of the literature which deals with the differences between the pre-industrial state in the presently more developed countries and the developing countries in recent decades.

##### (a) Population and the Industrial Revolution in England

137. The beginnings of modern economic growth have come to be associated with the start of the Industrial Revolution in England, which, as has been noted, affected not only manufacturing, but through fundamental changes in the technology and organization of production, changed radically the whole economic process and brought with it profound changes in the society and social structures.<sup>288</sup> The effective beginnings of this transformation are usually placed during the latter part of the eighteenth century, although some writers have pointed out that this process dated as far back as the middle of the sixteenth century,

<sup>288</sup> Mantoux, *The Industrial Revolution in the Eighteenth Century*... (1928, 1961 ed.), pp. 474-477; Ashton, *An Economic History of England*... (1955); Coleman, "Industrial growth and industrial revolutions" (1956); Deane, "The long-term trends..." (1961) and her *The First Industrial Revolution* (1965); Deane and Cole, *British Economic Growth*... (1962); Rostow, "Industrialization and economic growth" (1965). See also Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 126 ff.; Petersen, *Population* (1970), p. 402; Enke, *Economics for Development* (1963), p. 422.

and others have noted that the new order had been firmly established only by the middle of the nineteenth century.<sup>289</sup> Although recognizing that the conditions for the Industrial Revolution were created over a long period and that its completion took a considerable time, the majority of authors contend that the changes taking place around 1780 were such as to warrant the conclusion that the Industrial Revolution had its beginnings at that time.<sup>290</sup>

138. Since satisfactory estimates of production and income going back a long period in the past are scarce and often unreliable, inferences on England's economic growth during this period are to a great extent based on partial data or rough estimates. Many of the former relate to the growth of selected branches or products such as textiles, mining and metals which were of special importance for the country's development.<sup>291</sup> The available estimates suggest that a fairly rapid expansion may have occurred in the cotton industry and coal mining as early as the 1740s, but the fastest growth, it is asserted, in these and the iron industries took place in the last quarter of that century.<sup>292</sup> This is supported by Hoffmann's conclusion that 1780 was the approximate date when total industrial production increased for the first time at an annual rate in excess of 2 per cent.<sup>293</sup>

139. A number of writers have also stressed the importance of agricultural development during this period as a factor in economic growth.<sup>294</sup> Although data on agricultural production during the eighteenth century are virtually non-existent, a number of factors—such as the spread and intensification of cultivation associated with the enclosure movement, innovations and changes in the techniques of farming, including the introduction of new crops—are thought to have stimulated a significant

<sup>289</sup> Nef, "The progress of technology..." (1934) argued that the industrialization process started as far back as the sixteenth century. Ashworth, *A Short History of the International Economy*... (1952), pp. 19-23, 30-32, considered the middle of the nineteenth century as a crucial period in the industrialization process.

<sup>290</sup> Toynbee, *Lectures on the Industrial Revolution* (1884, 1913 ed.), pp. 1-7, spoke of the year 1760 as the eve of the Industrial Revolution. Among the writers who consider the starting point to be around 1780 are Ashton, *An Economic History of England*... (1955), p. 25; Hoffmann, *British Industry*... (1955), p. 30; Mantoux, *The Industrial Revolution in the Eighteenth Century*... (1928, 1961 ed.), pp. 25, 43, regarded the last third of the eighteenth century as a period of decisive change. Barre, *Economie politique*, vol. 1 (1961), p. 67, described the period from 1760 to 1850 as that in which the Industrial Revolution took place. For a discussion of these different points of view, see Deane, *The First Industrial Revolution* (1965), pp. 1-5.

<sup>291</sup> See section B of this chapter. Buchanan and Ellis, *Approaches to Economic Development* (1955), p. 126, suggest that the lack of national income estimates for this period is not as serious a shortcoming as is often assumed, since at that time there were only a few important industries, and their growth, together with that of agriculture, provide, they argue, a sufficient indication of over-all economic trends.

<sup>292</sup> Deane and Cole, *British Economic Growth*... (1962), pp. 55-56; Cole and Deane, "The growth of national incomes" (1965).

<sup>293</sup> Hoffmann, *British Industry*... (1955), p. 30.

<sup>294</sup> Court, *A Concise Economic History of Britain*... (1954), pp. 19-41; Bairoch, *Révolution industrielle et sous-développement* (1963), p. 31; and his *Agriculture and the Industrial Revolution* (1969); Buchanan and Ellis, *Approaches to Economic Development* (1955), pp. 126-127; Petersen, *Population* (1970), p. 406; Eversley, "Population, economy and society" (1965).

growth of agricultural production during this period.<sup>295</sup> Estimates of corn production, obtained through indirect methods by Deane and Cole, led them to conclude that until the 1770s output increased irregularly, but that from then on until the end of the century it increased steadily and accelerated further in the early nineteenth century.<sup>296</sup> One of the by-products of the progress in agriculture, according to a number of writers, was the effect it had on employment. The opening of new cultivated areas and the improved technology of production combined to create a more gainful employment of the agricultural labour force, but also released part of this labour to provide the needed industrial labour force.<sup>297</sup>

140. Tentative estimates of economic growth trends during the eighteenth century tend to confirm an upsurge during the latter part of that period. An assessment of over-all economic growth, based on statistics of international trade, was made by Deane and Cole who, although recognizing the difficulties involved in interpreting the type of data used, inferred the existence of several distinct phases in economic growth in the course of that century. The annual growth rate of net exports and imports was estimated to have been only about 0.5 per cent during the greater part of the first half of the century. The rate accelerated considerably after 1745, and even though it slowed down during the 1760s, its average for the quarter century from 1745 to 1771 came to 2.8 per cent. The final phase, from about 1770 to the early 1800s, was one of very rapid expansion with an annual growth rate of 4.9 per cent of net imports and exports.<sup>298</sup> On the basis of a number of indicators, Deane and Cole also derived rough estimates and indices of the growth of real output, which also provided evidence of an acceleration of growth in the late eighteenth century. According to these estimates, total and *per capita* income increased very slowly during the first decades of the century. A first spurt of growth occurred between 1745 and 1765 when total output is estimated to have increased by about 1.0 per cent annually and, although population growth also speeded up, *per capita* income gains were considerably higher than in the past. Between about 1765 and 1785 an acceleration in the rate of growth of population and a slowing down of the economy to a rate of growth of total product of about 0.7 per cent caused a virtual stagnation in the levels of *per capita* income. A crucial change took place, according to Deane and Cole, after 1785 when both total output and population started to grow much faster than ever before, but with the former increasing substantially more rapidly than population. Total output was estimated to have increased between 1785 and the

early 1800s at a rate close to 2 per cent annually while *per capita* income grew annually by nearly 1 per cent.<sup>299</sup>

141. As in the case of economic estimates, demographic data for England during the eighteenth century are scarce and the estimates that exist are either said to be inadequate to assess population trends during this period<sup>300</sup> or at the least are subject to a substantial margin of error.<sup>301</sup> It has also been pointed out, however, that despite their shortcomings, these data are consistent in that they indicate that an upward trend in English population growth started, although the initial increase may have been modest, around the middle of the eighteenth century.<sup>302</sup> While opinions as to the more specific patterns and the extent of the increase of population differ considerably, there appears to be substantial agreement on the fact that in the second half of the eighteenth century population expanded at a higher rate than in the first half of that century and the preceding ones.<sup>303</sup>

142. A considerable controversy has developed as to whether the speeding-up of population growth during this period must be attributed to a decline in the death rates or an increase in birth rates and, as to the former, what factors were instrumental in bringing about the decline in mortality.<sup>304</sup> The traditional explanation of the increase in population growth in England at that time was the fall in death rates.<sup>305</sup> This conclusion and the evidence on which it was based came to be questioned and an alternative explanation that attributed the increase in population to a rise in the birth rates was advanced.<sup>306</sup> The Industrial Revolution, according to this view, was accompanied by a number of economic and social changes conducive to a rise in fertility. The increasing demand for labour, the changes in the social structure and customs, increased mobility and internal migration, it is held, were

all factors which weakened the former restraints on early marriage and fertility, such as the widespread existence of apprenticeship, the predominance of the traditional rural society and so forth.<sup>307</sup>

143. Among those who have attributed the acceleration of population growth mainly to the decline in mortality, opinions differ as to the causes of the decrease. Traditionally, it was held that the fall in death rates was primarily the result of improvements in medicine and health<sup>308</sup> and the same view is also found in some more recent writings.<sup>309</sup> This interpretation was contested by others who argued that improvements in levels of living were the crucial factors in the reduction of mortality.<sup>310</sup> Sharp differences of opinion exist, however, concerning the effects of economic growth on the levels of living of the majority of people during this period. The view that the living conditions of the working class deteriorated during the early stages of the Industrial Revolution can be found in the writings of many authors, including Engels and Marx,<sup>311</sup> while the opposite view has been advanced by another group.<sup>312</sup> Another interpretation related to economic progress is that the decline in mortality during the initial phases of the Industrial Revolution responded to the disappearance of the "peaks" or surges in death rates which were characteristic of the pre-industrial period. Higher productivity in agriculture as well as a greater regularity of food supply, it has sometimes been argued, prevented the occurrence of the food crises which in previous periods often claimed large numbers of victims.<sup>313</sup> As in many other cases the evidence as to what was the net effect of the different factors involved on levels of living is contradictory and, on the whole, inconclusive.<sup>314</sup>

144. Although the extent and causes of the demographic change which occurred in eighteenth-century England are

(1971), pp. 30-34.

<sup>314</sup> Deane, *The First Industrial Revolution* (1965), p. 252; Deane and Cole, *British Economic Growth* ... (1962).

still a subject of discussion, it is generally recognized that the new population trends which manifested themselves at about the same time as, but did not necessarily coincide with, the beginnings of the Industrial Revolution, were closely linked to this process of economic and social transformation. Population growth has come to be regarded as an integral part of these processes, even though general interpretations of the underlying interrelations between population and economic growth find only limited support.<sup>315</sup> Thus the hypothesis that industrialization and the Industrial Revolution by themselves directly caused the population increase is not generally accepted, nor is the view that population growth was the dominant factor in bringing about the complex of changes known as the Industrial Revolution.<sup>316</sup> Population and economic growth, it has been argued, were bound by an intricate mutual relationship: without the growth of output in the eighteenth century, population growth, as it occurred, could not have continued, but also without the increased population, which never reached levels high enough to jeopardize economic growth, the Industrial Revolution in England would have been retarded.<sup>317</sup>

#### (b) *The experience of the other countries of early development*

145. The available statistical data for the pre-industrial period in the countries of early development as well as indirect evidence suggest that during many centuries prior to the beginnings of the modern phase of economic growth, levels of living and population growth were mutually interdependent. According to many authors, cyclical fluctuations in population growth were characteristic for this period as the number of people expanded until it started to press on resources and then was reduced by famines, epidemics or wars.<sup>318</sup> However, differences

<sup>315</sup> Ashton, *The Industrial Revolution* ... (1948), pp. 2-3, argued that the outstanding feature of the social history of that time was the rapid growth of population; Eversley, "Population, economy and society" (1965); Cole and Deane, "The growth of national incomes" (1965); Deane, *The First Industrial Revolution* (1965), pp. 32-33.

<sup>317</sup> Deane, *The First Industrial Revolution* (1965), pp. 33-35; Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 33-34; Habakkuk, "The economic history of modern Britain" (1958) and his *Population Growth and Economic Development* ... (1971), pp. 46-48; Chambers, "Industrialization as a factor ..." (1960); Wrigley, *Population and History* (1969), pp. 145 ff. On the fact that population growth in England during this period was comparatively low, making progress possible, despite a modest rate of economic growth, see Spengler, "Capital requirements and population growth ..." (1956).

<sup>318</sup> Sauvy, *L'Europe et sa population* (1953), pp. 17-18, and his *Malthus et les deux Marx* ... (1963), p. 29; Habakkuk, "Population problems ..." (1963) and his *Population Growth and Economic Development* ... (1971), pp. 10-24; Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 28-29; Deane, *The First Industrial Revolution* (1965), p. 21; Eversley, "Population, economy and society" (1965). Some historians, however, have questioned the validity of this essentially Malthusian scheme. On the lack of a direct relation between harvests and population pressure and mortality see, for instance, Habakkuk, "The economic history of modern Britain" (1958); Utterström, "Some population problems ..." (1954), and in more general terms Wrigley, *Population and History* (1969), pp. 63-64.

in the levels of economic achievement with respect to the rest of the world emerged at an early stage in a number of European countries and areas of European overseas settlement.

146. Following its start in England, the Industrial Revolution spread to western and northern Europe, the countries of European overseas settlement and, more recently, the Soviet Union, southern and eastern Europe and Japan. The process of rapid industrialization is estimated to have reached France and Belgium by 1850 and to have started in the United States at that time. It spread during the second half of the nineteenth century to Germany, the remainder of western and northern Europe and towards the end of the century to Canada, Russia, Argentina and possibly Japan.<sup>319</sup> Since embarking on the process of economic growth, the rates of increases of income in these countries were very high, according to Kuznets. In the older European countries total production increased at rates which implied coefficients of multiplication of 6 to 24 times in a century; in the overseas areas of settlement this coefficient ranged from 22 to 34; and in Japan he estimated that it was over 50.<sup>320</sup> For most of these countries reliable population data for the eighteenth century are scarce, but according to the estimates cited earlier in this chapter<sup>321</sup> population growth in the more developed regions from 1800 on was higher than in the preceding century and continued so during the rest of the nineteenth century. Many authors have drawn attention to this association between the accelerated increase of population and the rapid economic growth which was found in the majority of the presently more developed countries.<sup>322</sup> Nevertheless, it has also been noted that population trends in these countries varied considerably and that the association between population and economic growth was much less clear in the case of a number of individual countries. Whereas in most countries population growth was high, in historical perspective, in some, such as France, population increased relatively slowly, while in others, such as the United States, the increase was exceptionally rapid.<sup>323</sup>

147. While the existence of an over-all positive association between population and economic growth has come to be generally accepted, it has, as in the case of England, given rise to a considerable amount of speculation on the nature of the relationship between population and

economic growth during the early phases of development. In general, as noted before in this chapter, it has been argued that the main cause of the speeding-up of population growth was the fall in mortality caused primarily by improved economic and social conditions.<sup>324</sup> In more general terms the character of the relationships appears, however, to be less determined. Although the point of view that demographic growth was the main factor in economic growth during the periods of industrial revolutions has found little acceptance, the contention that population growth was a stimulating and, according to some, even a necessary condition for the rapid growth of output is still widely held. Population growth, it is argued, promoted economic growth in a number of ways: it created expanding markets and the opportunities for economies of scale; it provided the necessary labour force which made possible the large increase in production; and it favoured, since labour was plentiful, the accumulation of capital and subsequent development. Conversely, the view is often found that population growth during this period was conditioned by economic growth and development. Some authors emphasize in this connexion the progress in agriculture which, by increasing the production of food, permitted the population, which in earlier times was held back by subsistence crises, to increase rapidly. Others stress the process of industrialization with its increased demand for labour, higher wages and changes in the social structure—such as, for instance, those favouring earlier marriages—as having induced higher population growth.<sup>325</sup> Population growth and economic growth, it has been said, interacted upon each other so that population increase during this period was sustained.<sup>326</sup>

## 2. THE RELEVANCE OF PAST ECONOMIC AND POPULATION TRENDS FOR THE PRESENTLY LESS DEVELOPED COUNTRIES

148. Sustained economic growth and new patterns of demographic trends are a recent phenomenon for the majority of the developing countries. Even so, some of the most advanced among these nations may have experienced significant economic and demographic changes since as early as the late nineteenth or early twentieth century, and few, if any, of the others remained unaffected by the growth of the world economy. Nevertheless, under the prevailing conditions only very limited benefits accrued to these nations as a result of their often marginal involvement in the world economy and the relations with the more developed countries, which failed completely as a direct and immediate propellant for economic growth. The purpose of this subsection is to consider to what extent the present conditions and situation in the less developed countries, especially with respect to demographic and related factors,

<sup>319</sup> These tentative "take-off" estimates are given by Rostow, *The Stages of Economic Growth* ... (1960), table 1, p. 38. See also Cipolla, *The Economic History of World Population* (1962), p. 24; Seth, *Theory and Practice* ... (1967), p. 7.

affect their capacity for development in comparison with the past in the presently more developed countries.

149. That conditions faced by the developing countries now differ greatly from those typical of the presently developed countries at the time they embarked on the process of modern economic growth has been generally recognized. There exists also a certain, though less than unanimous, conviction that in sum these differences make the outlook for development of the economically less advanced countries comparatively less promising. This is thought to be partly due to the more favourable position with respect to the underlying causes of economic growth in the presently more developed countries at the time they started to develop. Many of them had gone through a period of change and progress which extended over a number of centuries. As the outcome of political, social, cultural and geographical revolutions, they had already experienced some economic growth, were by contemporary standards comparatively advanced, had developed their economic organization to a fairly high degree and had created a substantial infrastructure at the start of their industrial revolutions.<sup>327</sup>

150. These factors found their expression in, among others, relatively high levels of *per capita* income in these countries. Differences in income have existed since early times, but during certain periods the countries of early development of western and northern Europe probably were considerably behind China, Italy, the Near East and the Far East in this respect.<sup>328</sup> At the time of the Industrial Revolution, however, the income per head in England and some European countries was probably considerably higher than in the rest of the world and most developing countries at present.<sup>329</sup> Kuznets, citing rough estimates made by Clark, noted that whereas the United Kingdom (excluding Northern Ireland), the United States and Sweden at the time of their take-off had in *per capita* terms an income equivalent to well above 300 international units, the corresponding figure was less than 140 for China in 1935 and around 240 for India in the 1940s.<sup>330</sup> In a later study he found that *per capita* income in the presently more developed countries at the beginning of their modern economic growth was, in all cases, with the notable exception of Japan, over 200 dollars (in 1965 prices) and in many instances substantially above that level.<sup>331</sup> Deane speculated that income per head in England and in some European countries in the eighteenth century

was closer to the levels of Argentina and Chile in recent times than to present day southern Asia or Africa.<sup>332</sup>

151. A number of underlying economic factors are thought to have facilitated and contributed as noted to the higher levels of income and their subsequent growth in the presently more developed countries. It has been asserted that at the beginnings of modern economic growth these countries were already economically more diversified than the developing countries at present. There existed a fairly well-developed exchange economy, the urban population represented probably a higher proportion than in the now developing countries and important differences existed with respect to the industrial structure of the labour force.<sup>333</sup> According to Kuznets, pre-modern agriculture may have accounted for around 65 per cent of the labour force and in some cases this figure was as low as 50 per cent in the developed countries as compared with 70 per cent and over in many developing countries.<sup>334</sup> Comparing the industrial structure of the labour force in nineteen developing countries in a recent period with that of Great Britain in 1831, Deane found that only five of the nineteen matched the share for all non-agricultural activities of the latter in 1831 and only one matched the proportion of the British labour force in mining, manufacturing and construction at the time.<sup>335</sup> The countries of early development were also in a more favourable position with respect to capital formation and productivity. Not only did higher levels of income make it easier to reserve a larger proportion for capital formation,<sup>336</sup> but, in addition, accumulation was rapid because wages could be kept down as contrasted to the situation in the presently developing countries, where capital formation at the cost of the worker's levels of living is in many instances considered socially unacceptable.<sup>337</sup> Finally, although even in absolute terms capital formation was low, economic progress could be comparatively rapid because existing techniques then, as opposed to at present, required only limited resources.<sup>338</sup> Because of its crucial role in economic development, special attention has been given to the role of technology. It is generally thought that, in principle, the developing countries can obtain great benefits from the large stock of knowledge and experience in technological and social inventions and innovations developed in the economically more advanced countries.<sup>339</sup> However, various authors have noted that,

apart from such problems as the lack of entrepreneurship and labour force skill and the limited import capacity for capital goods, the adoption by the developing countries of modern technology originating in the more developed ones is not without problems. Directed towards the need of the economically more advanced economies, modern techniques frequently are labour-saving and capital-intensive and thus not suited to the existing state with respect to factor proportions in the less developed countries.<sup>340</sup>

152. Among the factors which distinguish development in the past from that occurring now are the demographic and population characteristics. Demographic differences with respect to population size and density, population growth and its components are considered to have considerable implications for economic growth. Compared to the developing countries at present, the developed countries had in their pre-industrial stage relatively small populations: none of the developed countries, it has been noted, had a population much over 30 million at the beginning of their rapid economic development.<sup>341</sup> Not only was the population in the presently developed countries relatively small but their density was on the whole considerably lower than in many of the now developing countries, making for more favourable ratios of population to agricultural land and natural resources.<sup>342</sup> The significantly less favourable relation of population to agricultural and natural resources in the countries now in the process of development, especially in Asia, is thought to be reflected in the over-all density figure which is estimated to be three or more times higher in Asia than in most Western European countries at the beginning of modern economic growth.<sup>343</sup> Lower densities in the latter countries not only facilitated the agricultural revolution but also contributed to the sustained increase in agricultural production prior to that, thus creating the necessary conditions for the industrial revolution. Moreover, where land was scarce or where population began to press on resources, these countries had the frontiers of the New World and other areas of European settlement, which the less developed countries are now lacking.<sup>344</sup> Poverty in natural resources, it has been noted, is not an absolute obstacle to economic development, but in many developing countries, it is asserted, scarcity of natural resources not only affects the factor endowments adversely but may, in addition, create additional problems for capital accumulation.<sup>345</sup>

153. The fundamental demographic factor distinguishing the presently developed countries at the time of the beginnings of their modern economic growth from the countries now embarking on the process of development is the growth of population. The presently advanced countries, as has been noted, experienced their most rapid increase of population well after their take-off on to economic growth, and even then the rate of increase was relatively modest, except for the countries of overseas settlement. In contrast, in the presently developing countries the growth of population in recent decades has reached levels unprecedented in earlier history and much above those of Europe during the eighteenth or nineteenth century. Many writers agree that the higher population growth in the developing countries seriously affects their development outlook compared with that of the presently developed countries in the past.<sup>346</sup> Bairoch attributed the failure of the economically less advanced countries to develop their agriculture in part to the acceleration of population growth and the consequent pressure upon resources.<sup>347</sup> Spengler noted with respect to capital formation that although savings in pre-industrial England were low, *per capita* income increased because population increased also at a low rate, making possible, as other writers have noted, a "deepening" of capital.<sup>348</sup>

154. The differences in population growth reflect the widely divergent levels and trends of both fertility and mortality, as well as, for a number of countries, emigration. While the crude birth rate of the developing countries as a whole is still of the order of 40 per thousand population and even though rates as high as these were found during certain periods in the countries of overseas settlement, fertility in the countries of western and northern Europe was at the eve of the Industrial Revolution probably already considerably lower than that, being of the order of some 30 to 35 per thousand population.<sup>349</sup> Part of these differences, it is argued, reflect the difference in marriage patterns in Europe as compared with other regions as, in the former, economic considerations and social and institutional factors tended to raise the age of marriage and lower the proportion ever married.<sup>350</sup>

Despite the differences in crude birth rates and fertility, the major factor which accounts for the population growth differentials for the two groups of countries at comparative stages of development is mortality. Improvements in mortality conditions in the presently more developed countries proceeded, as has been noted before, at a very slow pace until well into the second half of the nineteenth century and for most of that period were linked to economic and social progress. In contrast, in the countries actually in the process of development, large gains in longevity became possible and were effected through the application of modern techniques in the fields of medicine and public sanitation.<sup>351</sup> In the absence of the opportunities for emigration on a sufficient scale, which existed in the case of the European countries,<sup>352</sup> the high and stable levels of fertility and the rapidly declining mortality imply that the developing countries have to face levels of population growth far in excess of those typical for most presently developed countries at the beginning of the period of modern economic growth.

155. The predominant view is that the differences, both demographic and non-demographic, setting apart the groups of more developed and less developed countries in their early stages of economic growth affect adversely the potential for development in the presently less developed countries. Nevertheless, it has also been noted that the historical experience of the presently developed nations is not necessarily a guide for the now developing countries. It is unlikely, it is asserted, that these countries will develop along the same historical lines as those of the countries of Europe and Northern America. New patterns of development may in fact already be emerging and rapid economic growth and development may be attained at a much earlier stage than was the case in the past.<sup>353</sup> It has also been argued, partly on the basis of the past experience of the presently developed countries and partly on the basis of recent tendencies in the developing countries, that present or future patterns of demographic change do not necessarily conform to those observed in the past. In this context, it has been asserted in particular that changes in mortality and fertility trends are found to be closely associated and that declines in the former in the developing countries may very well be followed by rapid decreases in fertility and in population growth rates to moderate or low levels.<sup>354</sup>

#### **E. Over-all view and some tentative conclusions**

156. As in the case of other aspects of the interrelations between population and economic growth and development, considerable progress has been made in recent

<sup>351</sup> On the greater ease of introducing new medical techniques than new economic ones in developing countries see Kuznets, "Present under-developed countries ..." (1960); Sauvy, *De Malthus à Mao Tsé-toung* ... (1958), p. 138.

<sup>354</sup> See Olin, "A note on historical birth ..." (1964); also Kirk, "A new demographic transition?" (1971).

years towards understanding the relationships between population and economic trends during the modern period. Even so, the empirical and comparative study of the interrelations between population and economic growth at the international level remains one of the least explored areas in the field of demographic-economic interrelations. Part of the explanation for this deficiency lies in the scarcity of adequate data. Another factor is the complexity of the issues involved, which severely limit the scope and conclusions of such studies. Nevertheless, within these limitations, studies of the type described may contribute significantly to a better insight into the demographic-economic interrelations and, ultimately, to a more satisfactory basis for policy decisions.

157. The outstanding characteristic of the historical and recent trends in the relations between population and economic growth is their variability. Over-all trends in population and the growth of income during the greater part of modern history suggest the existence of a broad positive association between the two, as population tended to grow faster in that group of countries which also experienced more rapid economic progress. However, recent trends suggest the reversal of this association: over the last three or four decades, population has been growing more rapidly, and at levels unprecedented in earlier history, in the group of economically less advanced countries, where levels and growth rates of income are well below those of the more developed countries. The variety in this respect is even more pronounced in the case of individual countries; throughout modern history high and low rates of population growth have been found to have been associated variously with both high and low rates of economic growth.

158. The lack of a systematic and universal relation between the growth of population and that of income may be in part explained by the different patterns of demographic evolution, as reflected in fertility and mortality trends, at different times and in different areas. Although it is generally held that the process of modernization involves a demographic transition from high to low or moderate birth and death rates, the speed and timing of mortality and fertility change have varied greatly under different conditions. In broad terms it may be said that the demographic transition in the group of presently developed countries was associated in a general, but unspecified, way with the process of economic and social development. However, the experience of individual countries in this group did differ substantially and put into doubt the existence of a generally valid relationship between fertility and mortality trends, on the one hand, and economic and social development, on the other. Recent experience in the developing countries has further undermined the assumption of a consistent relationship between the components of population growth and development. In these countries mortality has been declining at a very rapid rate not as a result of economic growth and social advancement, but as a consequence of the introduction and spread of measures in the field of public health, sanitation and medicine. Thus the over-all, although tenuous, association which in the past linked the demographic evolution and growth trends to economic and social development no longer exists, and rapid

population growth, below the limits where its magnitude would cause a subsistence crisis, has become to a large extent independent of the rate of economic progress.

159. The period of modern economic growth has also seen, as part of the process of economic development, a rapid evolution in the industrial structure of the labour force and the urban-rural distribution of the population. Economic growth in the presently developed countries was accompanied by a structural shift in the labour force from agriculture to non-agricultural sectors and a shift from rural to urban residence. Structural change and, especially, urban growth, which on the whole had been relatively slow in most of the developing countries in the past, started to accelerate in recent decades; their rate of economic growth also speeded up. Although these over-all trends tend to confirm the existence of a general interdependence between development, industrialization and urbanization, the experience of different groups of countries and individual countries has varied considerably. Especially with respect to recent trends in the less developed countries, it has been argued by some that there is an imbalance between the pace of economic growth, on the one hand, and the changes in the industrial and rural-urban distribution of the labour force, on the other. Some other findings suggest, however, that patterns of industrialization and urbanization may vary considerably between different stages of development and that the observed trends are a reflection of this fact.

160. In considering the development outlook of the economically less advanced countries, considerable attention has been given to the different situation and conditions faced by these countries from those which characterized the presently developed countries at the time when they were embarking on the process of modern economic growth. In the presently industrialized countries the basis for subsequent development was laid over many centuries, resulting in relatively high levels of income, an already relatively well diversified economy and other characteristics conducive to economic growth. Conditions are very different in the developing countries, many of which have only recently attained political independence. Apart from economic factors, the demographic characteristics of the presently developed countries at the time of their take-off were also unlike those encountered in the countries now in the process of development. For instance, the ratio between population and resources, especially if the countries of overseas settlement are considered, was then much more favourable in the presently developed countries than it is in the developing countries today. More important, however, is the fact that population growth in the developed countries reached its highest level only well after development started and even then the growth rates, on the whole, were moderate. In sharp contrast, in many developing countries more rapid economic growth in recent decades was accompanied by an upsurge in population growth, and rates of population increase reached levels unknown in the developed countries in the past.

161. The fundamental issue, which has dominated the discussion of the relationship between population and economic growth during the post-war period, is the effect of demographic trends in the developing countries on

economic growth. By means of analytical studies and projections, it has been shown that rapid population growth and the characteristics associated with it, especially the "young" age distribution, place a heavy burden on the economy and its resources. A rapid increase in numbers implies an accelerated expansion of virtually all needs, including consumption, education, health, housing and other facilities, only to maintain existing conditions of living. The satisfaction of these needs would absorb resources which under alternative conditions would have been available for increasing levels of living. At the same time, there is little reason to assume, as has been illustrated in a number of models, that rapid population growth would increase the productive capacity of the economy enough to compensate for the faster increase of population. The faster growth of the labour force, associated with rapid population growth, is likely, according to these models, to lead to a less than proportionate increase in production as its positive effects are counteracted by the increasing pressure of a growing and larger population on other, scarce resources. Under the *ceteris paribus* assumptions of most demographic-economic models, growth of income would be faster the slower the growth of population.

162. The review of recent trends in population and economic growth in the developing countries confirms in part these conclusions, but in other respects suggests somewhat different findings. Although inferences based on comparisons of growth trends in population and income are affected by the quality and availability of data, which in many instances are subject to a considerable and unknown margin of error, subject to these qualifications, some tentative conclusions regarding the relation between population and economic growth appear to be possible. Data on the growth of total product or income and population in the developing countries suggest, in the first place, that the high rates of growth of population characteristic of these countries have not prevented economic growth. Rates of growth of *per capita* product in these countries indicate, in fact, that, in an historical perspective, economic growth in the post-war period for the developing countries as a whole was rapid. In addition, the results suggest that the interrelation between the growth of income and that of population was not as close as is often assumed. No association was found to exist between the growth of total product in the less developed countries as a whole and the growth of total product in the more developed countries, despite the large differences in population growth rates between these two groups of countries. Likewise, within the group of developing countries both the growth of total and *per capita* product were apparently unrelated to population growth. This does not mean, however, that high population growth in the less developed countries did not affect their economic growth. Data on levels of population growth according to levels of *per capita* income showed that population growth, on the average, was considerably more rapid in those countries where levels of income were lower. In order for these less developed countries at least to keep pace with the more developed ones, their total product would have to increase much faster than that of the more developed countries. This, as noted, did not

happen and a comparison between growth of *per capita* product and population growth revealed that the increase in levels of *per capita* income in the group of low-income, less developed countries remained significantly behind that of the more developed countries. Higher population growth in the less developed countries was thus associated with a deterioration of levels of living in these countries relative to the more developed countries, with a consequent widening in the income-gap as well, given their more rapid population growth with a relative increase of poverty, since low-income countries represent an increasing proportion of the world's total population.

163. The lack of a clear-cut association between the growth of population and that of income has led several writers to speculate that, in comparison with other factors and determinants of economic growth, the effects of population growth are not so predominant as to

manifest themselves clearly under different conditions. This does not imply, it is asserted, that population variables are not important, but that the relations between population and economic growth are part of a whole complex of interrelations and interactions, which suggest that under different configurations of factors and conditions, the impact on economic factors may vary. Comparisons of trends in countries with widely differing conditions, such as present themselves between the more developed and less developed countries and also within the latter group, fail to reveal a significant statistical association between population and economic growth. What results there are suggest, however, that rapid population growth, while not having prevented the growth of income in less developed countries, has held back the increase of levels of income and, probably, the whole process of development in these countries to a considerable degree.

## Chapter XV

### DEMOGRAPHIC PROJECTIONS

1. In the political and social ferment in the wake of the Second World War, the emergence of new independent nations, the drive for the development of economically under-developed countries and the rebuilding of economies devastated by that war have combined to stimulate national planning and development on an unparalleled scale. This has stimulated a corresponding demand by national governments and planning agencies for all types of demographic projections—including projections of population totals, subgroups by area, age, economic activity, rural or urban residence, agricultural or non-agricultural classification, educational level, and projections of households and families.<sup>1</sup>

2. Apart from planning purposes, demographic projections are needed for a clearer understanding of demographic phenomena. The projections provide quantitative measures of the potentialities of the present demographic situation and of the demographic processes which are under way and those which are foreseen in the light of present experience.<sup>2</sup> Since the projections are prepared on the basis of assumed trends in the components of population growth, the results present the net outcome of the interactions among these trends. For instance, given certain fertility and mortality assumptions, the projection technique makes it possible to determine the effect of different sex-age structures on the numbers of births and deaths and hence on the growth of the population. Similarly, projections provide a means of studying the effects of changes in birth and death rates on the age structure, dependency ratios etc. Because of this essential role in demographic analysis, projections and demography are now almost inseparable.<sup>3</sup>

3. In addition to the “realistic” projections, which represent assessments of future demographic change, there are also “benchmark projections” and “analytical projections”. Benchmark projections are designed to illustrate the demographic consequences of certain events which are admittedly not expected to happen during the

period covered by the projections. One example is the “constant fertility” variant of the United Nations projections used to study what would happen to the population of countries, regions and the world if fertility remained at its initial level. The purpose is to draw attention to the consequences of the currently high levels of fertility in many countries. Other examples are projections which assume a constant rate of growth. Analytical projections are used to study the influence of changes in the components of growth on the structure of the population, regardless of the extent to which these changes are related to reality.<sup>4</sup>

4. This chapter is concerned with the realistic projections which are most commonly needed for planning, as well as for understanding possible demographic changes in the future. The distinction between these projections and demographic predictions or forecasts is now generally recognized, although it has not always been so. This distinction was expressed clearly in 1943 by Thompson and Whelpton when they said “It is to be emphasized that they are not predictions of future population size, nor are they to be assumed to indicate the probable sex and age structure. They are, strictly speaking, merely statements of what the size and the sex, age, color, and nativity composition of the population would be at specified future times if birth rates, death rates, and immigration were to follow certain specified trends.”<sup>5</sup> Even if one assumes that the available demographic statistics are perfect, demographers cannot predict with certainty the future size of the population of any given area, country or region, particularly for a period beyond the immediate few years ahead, since it is impossible to foretell precisely future developments that will affect the net balance of the numbers of births, deaths and migrants;<sup>6</sup> this is particularly so for the future number of births, which is generally the most variable and least predictable. The best that a demographer can do is to project the size and sex-age composition of a population on the basis of certain assumed levels for each of the

<sup>1</sup> A partial bibliography compiled by the United Nations of principal studies related to projections published from about 1950 to the end of 1964 lists approximately 380 items, which suggests the intensification of the work in demographic projections. See bibliography contained in United Nations, *General Principles for National Programmes . . .* (1965). However, this is far from a complete inventory of the actual amount of work bearing on population projections that was done during those fifteen years.

<sup>2</sup> “The consequences of these phenomena and processes, their future effect, are considerably more important” than their past trends. Rosset, “On the cognitive value of demographic forecasts” (1968), p. 278. See also Jeanneney, *Economie politique* (1959), p. 40.

<sup>3</sup> Sauvy, *La population, ses lois, ses équilibres* (1944), p. 3.

<sup>4</sup> The literature includes many examples where projections showing the effect of the persistence of certain unfavourable demographic conditions have stimulated counteraction. For the role played by the projections in changing the unfavourable demographic conditions of the 1930s in France and Great Britain, see respectively, Sauvy, *L'Europe et sa population* (1953), p. 67, and Grebenik, “The development of demography in Great Britain” (1959), p. 194.

<sup>5</sup> Thompson and Whelpton, *Estimates of Future Population of the United States, 1940-2000* (1943), pp. 3-4.

<sup>6</sup> For a discussion of the distinction between projections and forecasts, see Grauman, “Population estimates and projections” (1959); and Siegel, “Technological change and long-run forecasting” (1953), p. 146.

components of its growth; and such predictive relevance as the projections may have rests primarily on the degree of correspondence between assumptions built into the projections and the trends as they actually develop.

5. Therefore, although this is not universal, it is generally felt that the projections should be prepared in several variants. A one-variant projection is narrow in the sense that it takes into account only one of the many possible directions of change. Different variants, on the other hand, give a picture of the possibilities, and provide a range which it is hoped will encompass actual events. There is no rule, however, concerning the number of variants, since this number depends on the length of the projection period, the degree of possible variability in the components of growth, and the reliability of the base data. The provision of additional variants used to be a time- and effort-consuming process, but with the availability of electronic computers, this difficulty no longer exists.

6. While there is no dispute over the necessity of presenting the assumptions together with the projections, there is difference of opinion concerning whether relative degrees of likelihood should be assigned to the different projections. Thus, on the one hand, the variants are sometimes distinguished by letters A, B, C etc., with no recommendation concerning the order of plausibility since, in the opinion of the authors, this would violate the "projections" nature of the results and turn them into forecasts.<sup>7</sup> On the other hand, the United Nations presents three variants which are designated as "medium", "high" and "low". "The 'medium' estimates are intended to represent the future population trend that now appears most plausible in view of what is known of past experience and present circumstances . . . . The 'high' and 'low' variants are intended to represent upper and lower boundaries of a zone of greatest plausibility . . . . It must be emphasized, though, that future trends outside the limits of the 'high' and 'low' variants are by no means impossible."<sup>8</sup>

7. For the population projections to be of practical use in drawing up plans and in taking action, selection has to be made from among the variants; and since in many cases the user of the results is not a demographer, he will want the selection to be made for him by a competent person. The demographers who prepared the projections in national institutions or international organizations are often in a situation where it is necessary for them to "recommend" one of the variants which they have prepared. Such a recommendation is not considered to violate the "projections" nature of the figures by turning them into forecasts or predictions,<sup>9</sup> in so far as the

<sup>7</sup> United States, Bureau of the Census, "Projections of the population of the United States, by age, sex, and color to 1990 . . ." (1967).

<sup>8</sup> United Nations, *World Population Prospects as Assessed in 1963* (1966), p. 6.

<sup>9</sup> This view was challenged by Dorn: "Predictions, estimates, projections, forecasts; the fine academic distinction among these terms is lost upon the user of demographic statistics. So long as numbers which purport to be possible future populations are published they will be regarded as forecasts or predictions irrespective of what they are called by the demographers who prepare them." Dorn, "Pitfalls in population forecasts and projections" (1950), p. 326.

assumptions are given along with the projections and other variants are also provided so that the users can select another projection to replace the recommended one if they find it more appropriate to do so.

8. Built-in provision for future revisions is another essential requirement of good demographic projections.<sup>10</sup> The results are thus viewed as a system of successive approximations to a picture of the demographic situation in the future in the light of new, more accurate or more detailed data giving better information on the present and the past, indicating changing or emerging demographic trends.

9. In a general sense the material presented in every chapter of this study has relevance to the projection of population. The future changes in the size, composition and geographic distribution of population depends first of all, as a sheer matter of arithmetic, on trends in births, deaths and migration. These trends, in their turn, depend on the influence of changing economic, social, demographic and other circumstances, constituting the subject-matter of several chapters. Future population changes themselves, as has been variously observed, will modify many of these circumstances with the possibility of additional, secondary, effects on the population trends which, if important, may also have to be taken into account in the projections.

10. Specifically, this chapter is devoted mainly to a brief review of the evolution of demographic projections in historical perspective, the major recent efforts towards developing projections for the world to the year 2000, and the broad implications of the projected trends for economic and social development programmes. In addition to projections of total population and its sex-age structure, projections of the economically active population, urban and rural population, agricultural and non-agricultural population, and projections of population by some educational characteristics, and of households and families are also considered.

11. Since the focus of this chapter is on demographic projections on a world-wide and regional basis, much of the work discussed is inevitably that done by the United Nations and the specialized agencies where such work is largely centred. A comprehensive review and discussion of the work on demographic and related projections done in the different countries at national and subnational levels is, of course, not possible within the scope of a single chapter. It should be recognized, however, that the greatest significance and use of the results of projections is at the country level.

#### A. Demographic projections in historical perspective

12. The predominant problem of demographic projections has been and remains that of forming, on the basis of observations already made, assumptions concerning the future trends of change. As can be seen from the history, the formulation of these assumptions has often been influenced by two factors: the availability of data and prevailing population theories.

<sup>10</sup> United Nations, *General Principles for National Programmes . . .* (1965).

13. In a situation where no data on births, deaths or migrants were available, it is not surprising that the early projections dealt only with total population, and used very simple methods. Thus in the very early population projections for England, made by Gregory King towards the end of the seventeenth century, the argument on which the assumptions were based was along these lines: the population of the Kingdom had doubled in the previous 435 years, probably the next doubling would take place in 600 years, but then the next doubling in all probability would take place after another 1,200 or 1,300 years.<sup>11</sup> Actually in the pioneer days of the seventeenth and eighteenth centuries, extrapolation on the basis of the speed of doubling was the most common form of projection. In addition to King, Petty, Graunt and Benjamin Franklin all used this approach.<sup>12</sup>

14. Malthusian theory, which implies a geometric rate of growth of population (see chapter III), provided a means of estimating future population. Malthus himself calculated projections aimed at illustrating his theory and presented them as follows: "Let us call the population of this island eleven million, and suppose the present produce equal to the easy support of such a number. In the first twenty-five years the population would be twenty-two million, and the food being also doubled, the means of subsistence would be equal to the increase. In the next twenty-five years, the population would be forty-four million, and the means of subsistence only equal to the support of thirty-three million . . ." <sup>13</sup> It is to be noted, though, that Malthus was of the opinion that "no estimates of future population or depopulation, formed from any existing rate of increase or decrease, can be depended upon".<sup>14</sup> He attributed unsuccessful predictions mainly to the irregularity of epidemics, sickly seasons, famines and the associated changes in the number of births.<sup>15</sup>

15. The complete and regular censuses which began in the eighteenth and nineteenth centuries in some countries were necessary before the early guesses as to the future population could be replaced by more serious estimates. Enumerated population totals then provided a basis for extrapolation by means of mathematical formulas which express total population as a function of time, without taking any special account of fertility, mortality, migration or age distribution. The forecasts prepared during the early years of the nineteenth century assumed an indefinite increase in population at a geometric rate.<sup>16</sup> By the middle of the century, however, the

belief that population could continue to increase according to the Malthusian Law was being questioned, and projections based on a decrease in the rate of growth were prepared.<sup>17</sup> Later on, by the turn of the century, some persons trained in the more rigorous disciplines of mathematics began to offer mathematical alternatives to the Malthusian formula. Pritchett restated the general law of population growth as one that involves a constantly decreasing rate, and suggested a third degree polynomial in time as a means of estimation.<sup>18</sup> Bowley used least-square fittings of second and third degree parabolas.<sup>19</sup> It was shown by Wolfenden that the populations of the Canadian provinces could be estimated closely by such methods.<sup>20</sup> Pearl and Reed obtained improved results by adding a logarithmic component to the second degree parabola.<sup>21</sup> Bowley, moreover, obtained a close approximation of the population of England and Wales from 1801 to 1911 by means of the integral of what was then termed "the normal error function".<sup>22</sup> It was realized, however, that "there is no necessary relation between the goodness of fit of a curve to past observations and its reliability for forecasting purposes. A curve may fit the data for the past one hundred years with a high degree of accuracy, and yet fail to predict the situation for the next year or so."<sup>23</sup>

16. Curve fitting methods of this kind are generally satisfactory only for short-range predictions because they usually fail to allow sufficiently for the eventual slowing of growth rates. Several analytical expressions have thus been suggested which would permit the rates of growth to approach limiting values. These include Gompertz's,<sup>24</sup> Makeham's,<sup>25</sup> and several functions discussed by Knibbs.<sup>26</sup> The most famous of these curves is the logistic, which has two different types of theoretical foundation. Thus in Verhulst's development in 1838,<sup>27</sup> the logistic resulted from a physical concept of population growth, namely that the obstacles to population expansion increase in proportion to the ratio of the superabundant

<sup>11</sup> King, "Natural and political observations . . ." (1696; 1936 ed.), particularly pp. 24-27. King gives projections for the total population of the Kingdom at the turn of each century up to the year 2300 and of London up to the year 3000.

population to the total population.<sup>28</sup> On the other hand, the Pearl-Reed development in 1920 was conceived in biological rather than physical terms, assuming, as their experiments on the fruit-fly *Drosophila* showed, that populations tend to reach an upper limit beyond which they do not pass.<sup>29</sup> The logistic provided a tool for population projections whose nature was in harmony with national ideas about the broad pattern of population growth and which has the theoretical merit of describing diverse types of growth phenomena. The curve was then widely used in making projections of total population.<sup>30</sup> Pearl and Reed also showed that component logistics may be assumed in order to represent successive cycles of growth,<sup>31</sup> and adaptations of the logistic were widely used.<sup>32</sup> The utilization of the logistic in projections of human populations was criticized, however, as being too mechanistic and not allowing for voluntary control over fertility and the influence of social and economic factors on the components of growth.<sup>33</sup>

17. There has also been discussion of the standard error of the ensuing estimates, and it was shown that this error increased with time.<sup>34</sup> It was observed early in the 1950s that the population of several countries, particularly France, Italy, Japan, Norway and Sweden were already very near the ultimate levels predicted for them from the logistic fitted by Pearl and Reed in the early 1920s.<sup>35</sup>

18. Transition theory (see chapter III) also provided a basis for some population projections. Among numerous projections which have been calculated in relation to this framework of thought are those prepared by the United Nations in 1951, where the world was divided into three groups corresponding to the phases of transition, and the assumptions concerning future trends in the crude birth and death rates were made accordingly.<sup>36</sup> These phases

<sup>28</sup> Applying this formula to the population of France, Verhulst obtained the ultimate maximum of about 40 million. He commented on the enormous size of this figure, referring to the calamities which must necessarily be caused by such rapid increase of population. See his "Recherches mathématiques sur la loi d'accroissement..." (1845), pp. 37-38.

of transition are of course generally taken into account in formulating the assumptions concerning future fertility and mortality trends. This has been the case with all the projections of the United Nations ever since the projections of Europe and the USSR were prepared for the League of Nations.<sup>37</sup>

19. Another serious drawback in the use of a growth curve to represent the trend of total population is that the procedure completely disregards the structure of the population, particularly by sex and age, and the influence of this structure on the growth of the population. Undoubtedly the lack of data has been a reason for this neglect. As comparable data from censuses and vital registration became increasingly available in the 1920s and 1930s, the component method of projection came into use. Special mention should be made, however, of the earlier contributions of Farr and Cannan to this approach. Farr in 1873 used a component basis to project a population backwards into the eighteenth century.<sup>38</sup> Cannan in 1895 used a procedure which is essentially the component method to prepare projections for England and Wales and to show that the results are substantially different from those obtained by using a constant rate of growth.<sup>39</sup> The method was applied by Bowley in 1924-1926<sup>40</sup> and by Whelpton since 1928.<sup>41</sup>

20. Systematic attention was paid to demographic projections only with the development of the component approach. In fact, interest in projections by this method has exerted a unifying force in demography, since the method involves a joint application of knowledge concerning trends in the components of change, namely fertility, mortality and migration. The method naturally gives more insight into the way in which population changes and yields valuable results in the form of future estimates of birth and death rates, dependency ratios etc.

21. In simple terms, the method consists in applying assumptions concerning future trends in fertility, mortality and migration to the sex-age structure of the population in the base period of the projection. Each sex-age group is carried forward in time by means of assumed probabilities of survival; the births which are added to the population during the projection period are estimated by applying projected age-specific fertility rates to the projected numbers of females in the reproductive ages; and the estimated numbers of births are carried forward in time by means of projected probabilities of survival. The resulting sex-age structure in any future year is then adjusted by adding or subtracting the assumed numbers

of future migrants in each sex-age group.<sup>42</sup> Until recently the method was applied only to populations with sufficiently accurate vital registration and censuses, but the development of demographic techniques has made it possible to estimate the basic sex-age structure—and/or the initial levels of fertility and mortality for countries lacking good statistics—from a series of models, thus widening the scope of the use of the component method. The most recent projections prepared by the United Nations, namely those made in 1968, use this approach for many developing countries. The component method has recently been developed further into a simulation of human behaviour, that is, a procedure whereby a probability of marrying, giving birth, migrating, and dying within a given interval in the future is estimated for each member of the population.<sup>43</sup>

## B. Regional and world projections

### 1. DEVELOPMENT OF COUNTRY PROJECTIONS

22. In the late 1920s, projections of total population by sex and age began to flourish. These projections were closely related to the cultural, economic and political settings of the different countries. Thus, in the West, there was much interest in projections since it was realized that the continued decline of the birth rate would make an eventual decline in total population inevitable unless the trend was reversed. In the countries of Eastern and Southern Europe, on the other hand, increasing awareness of the pressure of rapidly increasing populations on limited agricultural and industrial resources stimulated a demand for projections of future population trends. Finally, several countries began a race for demographic armament for a war that all feared would come.<sup>44</sup> Fundamental roles in this upsurge of work on projections were played by Whelpton<sup>45</sup> and Sauvy.<sup>46</sup>

23. The simplest form of component projections assumed the continuation of the most recent probabilities of survival, and an annual number of births equal to

that of the base year.<sup>47</sup> A more common type of component projection held constant specific patterns of both fertility and mortality as of a certain date, frequently that of the base year.<sup>48</sup> Many of the projections based on such assumptions constituted only one variant (a benchmark projection) in a series of projections, the remainder of which involved assessments of possible future trends in mortality and fertility.

24. So far as mortality assumptions were concerned, the most recent life table of the country, or of some other country with similar circumstances, was used in many of the projections. Others assumed certain declines in mortality. Attempts to project the rate of decline observed in the recent past also have been made. Gini and Finetti<sup>49</sup> made one estimate for Italy in which they extrapolated the trends of various age groups with the mortality of New Zealand as the ultimate goal. Glass carried out a detailed analysis in which he used the generation method for the extrapolation of mortality rates.<sup>50</sup> In general, estimates of future fertility were either based on certain assumed ratios of decline in the age-specific fertility rates or on the extrapolation of past rates of change by various methods. Before the mid 1930s, few projections assumed a rise in fertility; a common assumption was that fertility would fall until a definite date after which it would remain stationary. Some of the early projections were based on estimates of trends in the number of marriages and the average number of children per marriage,<sup>51</sup> and some made assumptions concerning trends in the proportion married.<sup>52</sup> The problem of making reasonable estimates of future migration was so nearly insoluble in the pre-war period that most component projections ignored it completely. Where estimates were made they usually assumed a fixed number of migrants annually.

25. Many of the projections mentioned above were prepared in three or more variants, thus giving probable lower, middle and upper estimates. Thompson and

<sup>42</sup> A description of this method is given in United Nations, *Manual III: Methods for Population Projections by Sex and Age* (1956).

(1938).

<sup>49</sup> Gini and Finetti, "Calcoli sullo sviluppo futuro ..." (1931).

<sup>50</sup> Glass, "The population problem and the future" (1937).

<sup>51</sup> Kahn, "Zur Erkenntnis der Bevölkerungsbewegung ..." (1931); and his *Der internationale Geburtenstreik, Umfang, Ursachen* ... (1930); Baudhuin, "L'avenir de la population belge" (1931); Creft, *Etude sur l'évolution des charges* ... (1937).

<sup>52</sup> Due to the late average age at marriage and the high proportions remaining unmarried, Wicksell and Quensel, "Prognoser över Sveriges folkmängd ..." (1938), made four alternative estimates for the Population Commission of Sweden to illustrate what would happen if population policies could be initiated that would result in decreasing the age of marriage and increasing the proportion married.

Whelpton<sup>53</sup> in 1934 presented twelve different sets of estimates for the United States, using various combinations of high, medium and low fertility and mortality with and without migration. As mentioned earlier, this multivariant feature has become very common in recent years.

26. Formidable problems faced technicians who wished to construct realistic projections by the component method once that method had matured. They involved assumptions as to the frequency and magnitude of essentially unpredictable events as well as affirmations of faith concerning the nature of the political, social and economic life of the future. The *a priori* assumption that future populations would develop as orderly extensions of the trends of interwar years became increasingly questionable,<sup>54</sup> particularly since there were new attitudes towards the number and spacing of children, age at marriage and tendency to marry,<sup>55</sup> and with the gradual realization that a fertility decline from the high levels experienced in developing countries can be expedited by family planning programmes. Demographers working in the field of projections also had to face the serious problem of the inadequacy and inaccuracy of the basic demographic statistics for the majority of the world's population. In spite of the hazards and the growing skepticism as to the possibility of accurate predictions—which reflects a growing maturity of demography—interest in demographic projections continued to increase due mainly to two factors: the need for projections in planning and the gradual progress achieved in research in the various fields of demography—particularly fertility analysis—which made possible the application of new approaches and the consideration of trends in more of the factors which influence fertility than was possible in the pre-war years.<sup>56</sup>

## 2. DEVELOPMENT OF REGIONAL AND WORLD PROJECTIONS

27. Projections are often prepared or assembled in comparable form for regions or groupings of countries. A set of population projections for the individual countries of Europe and the USSR, prepared for the League of Nations, represented the first comprehensive activity of an international organization in this area.<sup>57</sup> Later,

<sup>53</sup> Thompson and Whelpton, *Estimates of Future Population by States* (1934).

<sup>54</sup> Taeuber, "Literature on future populations 1943-1948" (1949), p. 2.

<sup>55</sup> The projections prepared for the British Royal Commission on Population dealt separately with the spread of childbearing by marriage duration, and the assumptions included changes in respect of each of the components. See United Kingdom, Royal Commission on Population, "Population projections for Great Britain 1947-2047" (1950), pp. 240-303.

<sup>56</sup> The following works contain bibliographies on population projections by sex and age: Glass, *Population Policies and Movements in Europe* ... (1940), pp. 468-472; Notestein *et al.*, *The Future Population of Europe and the Soviet Union* (1944), pp. 219-234; Taeuber, "Literature on future populations 1943-1948" (1949); United Nations, *General Principles for National Programmes* ... (1965), pp. 31-60.

<sup>57</sup> Notestein *et al.*, *The Future Population of Europe and the Soviet Union* (1944).

in the 1950s, the United Nations prepared a series of regional projections.<sup>58</sup> Other important contributions have been made by the Organisation for Economic Co-operation and Development,<sup>59</sup> the Institut national de la statistique et des études économiques (France),<sup>60</sup> and the United Nations Latin American Demographic Centre (CELADE).<sup>61</sup>

28. A number of estimates of future population of the world have been made by demographers. Pearl's logistic projection, prepared in 1936, implied a declining rate of growth which would result in a maximum of 2,645 million by the end of the twenty-first century.<sup>62</sup> Notestein in 1945 obtained a total of 3,300 million for the year 2000 by summing projections for the major areas.<sup>63</sup> This result suffered not only from inadequate data for large parts of the world, but also from an underestimation of the extent of mortality decline in the developing countries, and from a lack of anticipation of the reversal of the downward fertility trend in developed countries. A slightly greater rate of population increase was assumed by Clark in 1949; projecting the growth of world population at one per cent per annum, he estimated a total of 3,480 million people by 1990.<sup>64</sup> More recently Boyarsky, by dividing the world's population into twelve socio-economic groups and using the concept of a "hypothetical stationary population" to project the total population of each group, arrived at an estimated total population for the world in the year 2000 between 4,200 million and 5,000 million.<sup>65</sup> Another estimate of 4,500 million in the year 2000 was provided in 1966 by Bogue who assumed that the population growth rate of each region in the world was already declining in 1965 and would reach zero at the end of the century.<sup>66</sup>

29. The most intensive and systematic work on world and regional population projections has been carried forward since the 1950s by the United Nations, in collaboration in more recent years with various of its regional offices. The first set of world population projections prepared by the United Nations was published in 1951<sup>67</sup>

<sup>58</sup> United Nations, *The Population of Central America* ... (1954); ———, *The Population of South America, 1950-1980* (1955); ———, *The Population of South-East Asia* ... (1958); and ———, *The Population of Asia and the Far East, 1950-1980* (1960). See also Ducoff, *Human Resources of Central America* ... (1960).

<sup>65</sup> Boyarsky, "A contribution to the problem of the world population ..." (1967).

<sup>66</sup> Bogue as mentioned in Macura, "The long-range outlook ..." (1968), p. 20.

<sup>67</sup> United Nations, "The past and future growth of world population ..." (1951).

and covered the period 1950-1980. This set was prepared by projecting in three variants the birth and death rates (and hence the rates of growth) for three subdivisions of the world: regions with low fertility and mortality, regions where mortality had declined substantially and fertility in a lesser degree, and those where both fertility and mortality were high. This work was successively revised and extended with the advent of more adequate data and improved methodology. The second set of projections, prepared in 1954, had a similar approach.<sup>68</sup> In the 1958 revision, the component method was used and applied to regional models of age structure to derive regional projections by age for the period 1950-2000, in three variants. Medium variant country projections up to 1975 were then derived numerically from the regional totals.<sup>69</sup> Much more elaborate procedures were used in the fourth and fifth revisions, namely those undertaken in 1963<sup>70</sup> and 1968 respectively.<sup>71</sup>

30. In the 1963 revision, the world was divided into twenty-four geographical regions grouped into more developed and less developed areas on the basis of their demographic characteristics. For each of these twenty-four regions, the projections up to the year 2000 were prepared by the component method on the basis of the 1960 sex-age distribution. For this purpose, the United Nations model life tables were used in estimating the number of survivors, projected sex-age-adjusted birth rates were used to estimate the number of births, and in the regions where international migration was still sizable, an adjustment was made for this factor in the total population. In addition to the low, medium and high variants, a "continued fertility level" variant was calculated; this level could serve as a benchmark, indicating the implications of the absence of a fertility decline and also as a means of assessing approximately the extent to which each of the other variants is influenced by the assumed fertility declines. Projections of the total population for each country to the year 1980 were also provided in one variant.

31. The 1968 revision was carried out on a country-by-country basis. It was therefore necessary to evaluate and adjust the available data for many countries, and in some cases it was necessary to use a model sex-age structure. The revised projections also had the following main characteristics: (a) they were prepared for the developing countries in four variants: medium, high, low and constant fertility, and in one variant only for the developed countries; (b) they provided distributions by sex and five-year age groups; the results also were interpolated to derive estimates by single years of age between ages 5 and 24; (c) model life tables were used in projecting the numbers of survivors, and in estimating the numbers of births, age-specific fertility curves were used; (d) use was made of recent reliable national projections (available for most

of the developed countries and a few developing countries); (e) in addition to country projections for the period 1965-1985, regional and global projections were also prepared until the year 2000. The use of the electronic computer made it possible to produce the results in this detail, to calculate several implied measures such as birth and death rates, dependency ratios etc., and to produce the results in a form that would serve as a basis for preparing other projections, such as those for the economically active population, urban-rural population, agricultural and non-agricultural population, and the population enrolled in schools, and projections for households and families.

32. It can thus be seen that the United Nations projections have gone through a stage of marked uncertainty and much painstaking research.<sup>72</sup> For instance, the first three rounds, namely those of 1951, 1954 and 1958, gave as a "high" estimate of the world population for 1980 the figures 3,640, 3,990 and 4,280 million consecutively. The high variant of the 1958 revision was lower than the medium variants for 1980 as assessed in 1963 and 1968—4,330 and 4,460 respectively. Commenting on the various revisions, Macura observed that the gradual acquisition of new information and improvement in methods had usually resulted in higher estimates of future population.<sup>73</sup>

### 3. WORLD POPULATION PROSPECTS AS RECENTLY ASSESSED

33. The discussion below is based on the results of the United Nations projections to the end of the century prepared in 1968.<sup>74</sup> While the results of these projections are available in far greater detail than any other global projections, this is not to say, of course, that they are more accurate than others in the sense that they have a higher probability than others of being closer to reality in the future. It may be said, however, that Bogue's "fertility control approach which assumes that about 1965 the birth rate of all regions of the world was already declining at a faster rate than the death rate" is too optimistic.<sup>75</sup> It is also to be noted that Boyarsky's "social system and economic development" estimate for the world in the year 2000 is close to that of Bogue,<sup>76</sup> and therefore appears also to be too low.

34. The projections clearly illustrate the demographic implications of the unprecedented growth in world

<sup>72</sup> See in this regard Grauman, "Success and failure in population forecasts" (1967).

<sup>73</sup> Macura, "The long-range outlook ..." (1968).

<sup>74</sup> United Nations, *World Population Prospects as Assessed in 1968*, to be issued as a United Nations publication.

<sup>75</sup> See Durand, "Comments on Macura" (1968), pp. 43-45.

<sup>76</sup> Notestein argued that the fertility assumption for China in the United Nations 1963 projections is too low and that the rate of improvement in the projected level of mortality is too slow. In his opinion it would be more reasonable to postulate an annual growth rate for Mainland East Asia between 1960 and 2000 equal to South Asia's 2.3 per cent instead of the 1.2 per cent implicit in the medium variant of the United Nations projections. This would lead to an upward adjustment of 500 to 600 million in the projected figures for the year 2000 for Mainland East Asia, the less developed regions and the world. See Notestein, "Population growth and its control" (1969), pp. 14-15.

SOURCE: United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

Note: The totals for the world, developing and more developed regions have been adjusted to take into account discrepancies between international immigration and emigration assumptions.

population brought about by reductions in mortality accompanied by little change in the high levels of fertility in most of the world's developing regions. Thus, the total world population, which was increasing at an average annual rate of only about 0.5 per cent throughout the nineteenth century, and 0.8 per cent in the first half of the twentieth century, was found to be suddenly increasing during the decade of the 1950s at the rate of 1.8 per cent per annum, in spite of declining rates of growth in the developed areas. The rate of growth of the world's population rose still higher during the 1960s and was estimated at about 2.0 per cent annually around 1970.

35. According to the medium variant, the total world population may continue to grow at a virtually constant rate of about 2.0 per cent annually until 1985. A downward trend would then start, ending with a value equal

to 1.7 per cent at the end of the century. In absolute numbers, the world population may increase from 3,300 million in 1965 to 3,600 million in 1970, 4,500 million in 1980, 5,400 million in 1990 and 6,500 million in 2000 (table XV.1). The population of the less developed regions is expected to increase during this period from 2,300 million in 1965 to 2,500 million in 1970, 3,300 million in 1980, 4,100 million in 1990 and 5,000 million in 2000.

36. Should the medium assumptions turn out to be true, the more developed regions, which had a total population of 1,037 million in 1965, would add 4 or 5 per cent to this total in each quinquennium. On the other hand, in the less developed regions, there would be a gain of about 13 per cent in each quinquennium up to 1985, and then a slight decrease to 10 per cent in the last quin-

quennium of the century. As a result of these differing growth rates, the population in the developing regions by the turn of the century is expected to be about three and a half times the projected figure for the developed regions in that year, while the ratio in 1965 was only a little over two to one (2.2 to 1).

37. Among the world's major areas, the largest addition to the population during the period under consideration is expected in South Asia, which now contains almost one third of the world's population. India, Indonesia and Pakistan are the main contributors to this total. India's population may increase from 487 million in 1965 to 1,084 million in 2000 (an increase of 123 per cent in 35 years). In the same years, Pakistan's population may increase by 187 per cent, from 116 to 334 million, and Indonesia's population by 143 per cent, from 105 million to 255 million. The area as a whole may consequently by the end of the century have an increase of 1,372 million persons. If the projections are correct, this would be one half of the total increase in all the developing countries combined, or 43 per cent of the increase in world population.

38. The next major area of importance with respect to additions of population numbers is East Asia where, although the pace of growth is expected to be moderate, the absolute increase will be very high. The bulk of the increment in this area's population is due to the expected growth of China's population, which is projected to increase from 700 million in 1965 to 1,176 million in 2000. Sizeable increases in total population are also expected in Latin America—from 246 million to 652 million—and in Africa—from 303 million to 818 million—during the same period.

39. The decade of the 1970s may be confronted with a higher rate of growth in world population than ever before experienced in the history of man, and one higher than is likely to be encountered again in the future. According to the medium projections, this growth rate will approximate 2.0 to 2.1 per cent annually during the decade. It will be 1.0 to 1.1 per cent annually in the developed regions, but 2.4 to 2.5 per cent in the less developed regions.

40. Among the major areas of the world, rates of growth are currently highest in Latin America and South Asia. Latin America is expected to maintain its very high rate of 2.8 to 2.9 per cent annually until about 1985—a result of its relatively low mortality compared to other developing areas. Then, as fertility decline becomes faster than mortality decline, the rate is expected to gradually decrease to 2.6 by the end of the century. In South Asia, where current high growth rates are mainly a reflection of very high fertility levels, a gradual decrease is expected, from 2.8 per cent around 1970 to 2.0 per cent around 2000. In contrast with the expected pattern of constant or declining growth rates in the other less developed regions, Africa is expected to show a rising growth rate trend during most of the period. The annual population growth rate in this major area, which was estimated at 2.6 per cent in 1965-1970, may rise to about 3.0 per cent by 1985, at which time the rate would be one of the highest in the world. It is only during the decade

of the 1990s that, according to the projections, the growth rate may decrease until it reaches 2.8.

41. In the major areas of the more developed regions of the world, annual population growth rates in the period 1965 to 1970 ranged from a low of 0.8 per cent in Europe to 2.0 per cent in Oceania, the latter rate being influenced by immigration into Australia and New Zealand, as well as by high fertility among the populations making up the remainder of this region. According to national projections of the developed countries, rates of population growth are shown to rise somewhat until about 1985 and then decline in North America, the Union of Soviet Socialist Republics, and in Australia and New Zealand; in Europe, on the other hand, the current rate is expected to continue declining slightly (table XV.1). The slight increases foreseen in the former areas will result for the most part from changes in population structure, as the only rise in fertility assumed is in the USSR.

42. Table XV.2 shows the vital rates implied in the medium projections for the world and its twenty-four regions. So far as the developed regions are concerned, little change is foreseen in either the crude birth rate or the crude death rate, the two rates remaining near 18-19 and 9 per 1,000, respectively. The slight increase in the implied birth rate from 18.6 in 1965-1970 to 19.5 in 1980-1985 is mainly due to changes in age structure favourable to higher crude birth rates. The slight increase shown in the crude death rate—from 9.1 to 9.6 per 1,000—is entirely due to the continued aging of the population, since further increases in expectation of life at birth are expected during this period (table XV.3).

43. Except for Eastern Europe, where a slight drop in gross reproduction rates was foreseen (table XV.3), fertility was expected to remain constant in the other regions of Europe until around 1985; the rise of one point in the crude birth rate of Northern Europe reflects changes likely to occur in the age structure of the population, rather than any expected increase in fertility. Increases of 2 to 3 points per 1,000 in crude birth rates appear in the projections for Northern America, the Union of Soviet Socialist Republics and Australia and New Zealand, but with the exception of the Union of Soviet Socialist Republics, where national projections are based on an assumed small increase in the gross reproduction rate, these trends arise from the changing age structure. Although expectation of life at birth in the Union of Soviet Socialist Republics is expected to rise from its present level of about 70 years to 72 years by 1980-1985, the increasing proportion of older persons in the population may bring the crude death rate up one point—from 8 to 9 per 1,000. Between 1985 and 2000, a slight fertility decline is generally assumed.

44. Tables XV.2 and XV.3 show that substantial increases in life expectancy and declines in the crude death rate are foreseen in all the less developed regions. On average in these regions, a gain of 15 years is assumed during the projection period in expectation of life at birth (from 50 to 65 years), while the crude death rate may decline from 16 to 8 per 1,000. All major areas are expected to share in these gains, although the pace of

improvement is expected to be somewhat slower in Latin America, where mortality was already at a relatively low level in the late 1960s. In that region, life expectancy at birth, which is estimated to have reached 60 years in the late 1960s, is expected to advance to about 71 years by the end of the century. The largest gains in life expectancy are expected to be registered in South Asia and East Asia, where mortality levels were still moderately high around 1970, and in Africa, where the highest levels of mortality prevail. In South Asia, life expectancy at birth may rise from 49 to 66 years during the projection period, in East Asia from 52 to 68 years, and in Africa from 43 to 59 years. According to these assumptions, only by the 1980s would Africa attain the mortality level existing in Asia in 1970.

45. Significant differences in probable fertility trends are also apparent among the major areas constituting the less developed regions. On the one hand, fertility—as measured by the gross reproduction rate—is likely

to remain relatively unchanged until about 1985 in the African region taken as a whole, as probable small declines in North Africa may be offset by opposing trends in parts of Middle Africa, where it is believed that improvements in public health may cause a rise in fertility. Fertility declines prior to 1985 have been assumed for only a few countries in sub-Saharan Africa which have adopted policies for population control. In contrast to the stability shown in the projected gross reproduction rates (table XV.3), the crude birth rate for Africa is shown to decline from 47 per 1,000 in 1965-1970 to 45 per 1,000 in 1980-1985 (table XV.2), but this trend would result from changes in age structure associated with declines in mortality. After 1985, some decline in fertility, which would reduce the gross reproduction rate from 3.1 to 2.5, is assumed for the remainder of the projection period. According to these assumptions, the birth rate of Africa would become 38 per 1,000 at the end of the century.

46. In Latin America a moderate decline in fertility is foreseen in the projections, bringing the gross reproduction rate for the region as a whole down from 2.7 to 2.0. The largest drop is expected in Tropical South America and Central America, while a smaller decline is likely in Temperate South America, where fertility is already rather low (table XV.3). In contrast to the moderate fertility declines assumed for Latin America, fairly sizable decreases are foreseen for South Asia and East Asia. In the former, the gross reproduction rate is assumed to fall from 3.0 at present to 1.6 in 1995-2000, and in the latter, from 2.1 to 1.2. The existence of family planning programmes in a number of countries, and the fact that fertility has already begun to decline in certain countries in these regions, have been factors in the assumptions of more rapid fertility decline. As shown in table XV.2, corresponding declines in the crude birth rate could be expected to accompany such changes in the gross reproduction rate.

47. Between now and 1985, the anticipated virtual equality of the declines in the death rate (from 16 per 1,000 in 1965-1970 to 11 per 1,000 in 1980-1985) and the birth rate (from 41 per 1,000 in 1965-1970 to 35 per 1,000 in 1980-1985) in the less developed regions would maintain a nearly constant rate of population growth of 2.4 to 2.5 per cent per annum throughout the period. After 1985, as the decline in the birth rate becomes faster, the projections imply that the rate of growth would gradually decrease to about 2.0 by the end of the century.

48. Not only changes in total population size, but also changes in the age structure of population have important implications for the planning of economic and social development. The striking contrast between the age structure of the population in the more developed and less developed regions is seen in table XV.4. Whereas children under 15 years of age constitute 28 per cent of total population in the developed regions, they make up 42 per cent of the total in the less developed parts of the

world. The more industrialized countries have an economic advantage over the less developed countries in that 63 per cent of their population is of working age, while the comparable proportion for the less developed countries is only 55 per cent. Also distinctly different is the proportion of elderly persons (65 years of age and over) in the population—9 per cent in the developed countries and only 3 per cent in the developing countries.

49. According to the medium projections, not very much change is expected to take place in the age structure of either major group of regions between 1965 and 1985. In the less developed groups, the percentage of children may decline slightly—from 42 to 40 per cent, with a slight increase in each of the other broad age groups. Whereas assumed declines in fertility cause the proportion of children to decrease, falling mortality, which has its greatest effect at the young ages, tends to partially offset this trend.

50. Africa, which has the highest proportion of children and the lowest proportion in the working ages at present, is the only major developing area where the short range projected trend of structural change in population is unfavourable—in the sense that the proportion of children is likely to increase (from about 43.5 at the beginning of the period to 45 in 1985) and the proportion of the economically active population is likely to decrease (from 54 to 52). The largest structural change in this period is predicted for East Asia, where the proportion of children in the population will decline from 37 to 32 per cent, according to the projections. South Asia, despite a substantial decline in fertility, shows only a small drop in the proportion of children in the population—from 43 to 42 per cent.

51. As fertility declines faster, more sizable changes may take place between 1985 and the end of the century. The projections for the less developed countries as a whole imply that during this period the percentage of children may decrease from 40 to 35 and the percentage at ages 15-64 years may increase from 56 to 60. It may be noted in table XV.4 that in the year 2000 the projected African age structure is virtually identical with its 1965

structure. An impressive change during the last 15 years of the present century is indicated for South Asia where, according to the projections, the percentage of children would drop from 42 to 35 and the percentage aged 15-64 would increase from 55 to 61. It is also to be noted that in none of the major developing areas except East Asia would the proportion of the old aged population (65 and above) reach as high as 5 per cent within the remainder of this century.

52. In the more developed regions, the percentage of children is expected to decrease further between 1965 and 2000—from 28 to 25, while the proportion in the ages of economic activity may remain virtually constant at about 63-64 per cent. On the other hand, the aging of the population, which is a main demographic problem in these regions, is expected to continue, the percentage in the age group 65 years and above rising from 8.9 in 1965 to 10.4 in 1985 to 11.4 in 2000. Aging of the population is most conspicuous in Europe, where the percentages aged 65 and over are 10.5 in 1965 and may reach 12.5 by the year 2000.

53. The anticipated future changes in the numbers in various functional age groups that are of particular relevance for development planning are shown in table XV.5. The importance of demographic factors in planning is evident from the fact that both the size and the growth of these functional groups are determined by the previous sex-age structure of the population and by fertility, mortality and migration experience.

54. Most noteworthy is the growth anticipated in the working-age population 15-64 years old, with its important implications for employment and capital requirements. In the less developed regions this stratum is expected to increase, according to the medium variant projections, by 145 per cent between the years 1965 and 2000. This increase, which amounts to about 1,800 million persons, constitutes an additional demand for employment and occupational training which has to be given serious consideration by the planners, together with the problems of the underemployment and unemployment of the existing labour force. On the other hand, the pro-

SOURCE: United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

Note: The totals for the world, developing and more developed regions in the year 2000 have been adjusted to take into account the discrepancies between international immigration and emigration assumptions.

jections indicate that this group would increase by only 42 per cent in the developed countries within the same period.

55. Equally important is the growth of the school-age population between ages 5 and 14. If the assumptions of the medium variant turn out to be true, this group would, by the year 2000, virtually double its 1965 total in the developing regions. Considerable regional variations may occur in the growth of this group; whereas the number of school-age population may increase no more than one fourth in East Asia, the corresponding figures for Africa and Latin America may approximate 180 and 150 per cent, respectively. The educational needs arising from these anticipated increases, which amount to about 570 million in the developing regions as a whole, will have to be studied carefully, together with the questions of achieving full enrolment and of improving the quality of the present education. It will be noted in table XV.5 that in the developed countries the increase in the size of this group anticipated in the projections is only 46 million in the thirty-five years under consideration.

56. The most rapid growth is implied in the projections of the old-age group (65 years and over), in the less developed as well as the more developed regions. It should be noted, however, that although the growth of this group is particularly rapid in the less developed regions (more than 200 per cent during the projection period), it constitutes only 5 or 6 per cent of the total population increase. On the other hand, the increase of about 80 per cent in the size of this age group in the more developed regions is particularly significant since it constitutes about 18 per cent of the total population increase.

57. Special interest attaches to trends in the female population of reproductive age. In the developing regions as a whole, the number in this group, according to the medium variant, can be expected to increase by 140 per cent between 1965 and the year 2000, and in Africa, South Asia and Latin America, increases of about 170 per cent were likely. Such rapid growth in the numbers of women in the fertile ages implies that there will be large increases in the absolute numbers of births, even if fertility rates decline. In contrast to the high growth rates foreseen for this group in developing regions, the average increase during the same period was expected to be only about 35 per cent in the developed regions.

58. The above data support the common view that world population trends for many years to come will be decisively influenced by trends in the developing regions. The crux of the population problem which will face the world in the coming years lies in the association of persistent poverty, illiteracy, underemployment and technological retardation with rapid growth of numbers in these regions. Available information also shows how difficult it is to achieve rapid economic development and bring about significant changes in the structure of the population under conditions of rapid population growth. Under such circumstances, those aspects of economic development and population structure and distribution which normally tend to induce a change in reproductive behaviour and reduce fertility may have only limited effect. However, a much more fruitful solu-

tion would lie in combining rapid economic growth and structural changes in the population with a rapid decline in fertility. Structural changes and changes in reproductive patterns may be mutually supporting and may speed up the demographic transition in the developing countries.<sup>77</sup>

59. Demographers, economists, sociologists, and the members of other disciplines cannot yet claim to have defined unequivocally the basic causal relationships in the disquieting association of poverty and retardation with unremitting rapid growth of numbers in the developing regions. Nor can they claim to have clarified what this association portends for the future of the economically disadvantaged nations and the world as a whole. Some of the implications, though, can be spelled out clearly enough. One which deserves particular mention is a need for increased international sharing of resources because of disproportions in population growth between the "have" and the "have-not" nations, and from opposite disproportions in the growth of income and wealth.<sup>78</sup> Above all, the unity of the world in respect to future population trends should be emphasized; a unity which, although comprised of many diversities,<sup>79</sup> still represents the destiny which the whole world must share.<sup>80</sup>

### C. Types of specialized demographic projections

60. In planning for social and economic development, neither population nor any socio-economic factor is regarded as an independent variable. Demographic changes partly determine social and economic changes, and the latter, in their turn, influence the population changes. In this complex of interacting factors, which constitutes the development process, it is very difficult to know explicitly the mutual relationships between numerous variables. This methodological problem, together with the lack of data in the necessary detail, is a serious handicap in the integration of demographic projections with other socio-economic projections into a comprehensive national plan. Attempts are already being made,<sup>81</sup> and the work in this field is enhanced by the recent development of simulation models.

<sup>77</sup> For a detailed elaboration which takes into consideration available projections of the economically active population, urban-rural population and agricultural and non-agricultural population see Macura, "Demographic prospects for the next thirty years" (1971).

<sup>78</sup> Durand, "A long-range view of world population growth" (1967), pp. 7-8.

<sup>79</sup> For a discussion of these diversities see: Macura and El-Badry, "Diversity or uniformity of demographic problems ..." (1968).

<sup>80</sup> Macura, "Demographic prospects for the next thirty years" (1971), p. 42.

<sup>81</sup> See, for example, Orcutt *et al.*, *Micro-Analysis of Socio-Economic Systems* ... (1961); Hyrenius, *New Techniques for Studying Demographic-Economic-Social Interrelations* (1965). For a summary of the results of an attempt to prepare comprehensive projections of the population by sex and age groups and by economic structure, as well as projections of households, see Yugoslavia, Institut Društvenih Nauka, *Demografska kretanja i projekcije* ... (1968).

61. In spite of the serious handicaps, independent work started in the late 1950s on projections of population by its socio-economic characteristics. Theoretically, the number of social and economic groupings of the population can be very large, depending on the size and composition of the national population and its geographic, residential, cultural, ethnic and economic diversity. In practice, however, a limited number of categories of population have come to be nearly universally recognized as of special importance in demographic and socio-economic analyses, and consequently in the collection and tabulation of census and population sample survey data.<sup>82</sup> These categories include classification of the population (a) by economic activity (or labour force) status, and for the economically active, their occupation and industry attachment; (b) by rural and urban residence, and within the urban, by city-size classes; (c) by agricultural and non-agricultural livelihood; and (d) by educational attainment, school attendance or literacy status. Attention has lately been given to projections of households and families in view of their importance as living units, consumption units and, in some cases, also production units.

62. Labour force, rural-urban, school enrolment, or projections of other socio-economic categories all involve projecting a part or section of the population of a country rather than the total population. This gives rise to rather distinctive conceptional and methodological problems. Definitional aspects become very important in determining the size and limits of the group or category being measured and projected. Comparability over time of the definitions used within a country affects the measurement of past and future trends, and problems of international comparability arise if definitions of the population group or category differ among countries. Secondly, the size and composition of the population group changes not only through births and deaths occurring within the group, but also by the entry or departure of persons into or from that group through acquiring or losing the group's definitional characteristics. Thus, for example, changes in the urban and rural population of a given country are produced not only by births and deaths occurring within these population sectors, but also, and very importantly, by internal migration between these sectors, by reclassification of previously rural localities into urban (as a result of population growth and achievement of urban size as administratively defined), or by annexation of hitherto rural areas within the administrative limits of a given city. Similarly, changes in the labour force of a country are produced not only by the size of the cohorts first entering the labour force (which are affected by past birth and age-specific death rates as well as current labour force participation rates), but also by withdrawals or retirements from and re-entries into

the labour force as well as losses to the labour force occasioned by deaths.<sup>83</sup>

63. The remainder of this section contains a brief summary of the methodology used in preparing projections of the types discussed above. Some of the major findings of available projections on a world and regional basis are also presented.

# 1. LABOUR FORCE

64. With the emphasis on planning for economic development which appeared in the period following the Second World War, the need for manpower projections became increasingly evident. Both projections of manpower supply, which are concerned with the numbers of persons likely to be available for work at future dates, and projections of manpower demand, which relate to the number of jobs likely to be offered in different sectors of the economy, are important in this connexion. Only manpower supply projections, which are based on the projections of total population by sex and age, are discussed here. Projections of manpower demand are not demographic projections but are based on expected trends in production and worker productivity; they are less widely available than supply projections, since the detailed types of data required in their preparation are frequently lacking.<sup>84</sup>

65. Some of the early efforts to provide projections of manpower trends consisted of no more than projections of population in the working ages, which were taken as the equivalent of the labour force.<sup>85</sup> Since nearly all

<sup>83</sup> For a discussion of conceptual problems associated with these types of projections, including brief guidelines as to data required and useful classifications of characteristics, see United Nations, *General Principles for National Programmes ...* (1965). See also Muhsam, "Projections of urban and rural population, economically active population ..." (1967).

<sup>84</sup> On the methodology of both manpower supply and demand projections, see United Nations, *Manual V: Methods of Projecting the Economically Active Population* (1971); Johnston, "The integration of supply and demand projections of labour force" (1969); Vimont, *La population active ...* (1960), deuxième partie; Bloch and Praderie, *La population active dans les pays développés* (1966), chap. 12. On the methodology for preparing manpower demand projections, see also Vimont, "La prévision de la demande de main d'œuvre" (1969); and his "La prévision des besoins en main d'œuvre ..." (1967); United States, Bureau of Labor Statistics, *The Forecasting of Manpower Requirements* (1963); Urquidí, "Problemas relativos a la previsión ..." (1967). For examples of projections of manpower demand, see Netherlands, Centraal Planbureau, *Een verkenning der economische toekomst-mogelijkheden van Nederland ...* (1955); ———, *De Nederlandse economie in 1970 ...* (1966); France, Commissariat général au Plan, *L'équilibre économique en 1961 ...* (1957), pp. 91-96; United Arab Republic, Institute of National Planning, *Manpower Planning in the United Arab Republic* (1966); Puerto Rico, Committee on Human Resources, *Puerto Rico's Manpower Needs and Supply* (1957); Organisation for Economic Co-operation and Development, *Education, Human Resources and Development in Argentina* (1967), chap. 20; ———, Mediterranean Regional Project, *Country Reports: Greece* (1965), pp. 44-47; Beckerman et al., *The British Economy in 1975* (1965), chap. 7; United States, Bureau of Labor Statistics, *Patterns of U.S. Economic Growth ...* (1970); Rogiers, "Les prévisions de la population active et de l'emploi ..." (1965); Scoville, "The occupational structure of employment ..." (1969).

<sup>85</sup> Such was the case with the early projections compiled by the Organisation for European Economic Co-operation which defined working-age population as consisting of males 15-64 years and

(Continued on next page)

<sup>82</sup> See, for example, United Nations, *Principles and Recommendations for National Population Censuses* (1958); and ———, *Principles and Recommendations for the 1970 Population Censuses* (1969).

men between the ages of 25 and 54 years of age participate in economic activities in all countries, whatever their level of development, trends in the numbers in this age group closely parallel those of economically active males of the same ages. Activity rates for men above and below these ages, however, and of women throughout the working ages, fall considerably short of the potential; they vary greatly among countries and change over time. In many countries also, participation by persons above or below normal working ages in economic activities is far from negligible. Trends in the working-age population alone are therefore inadequate to reflect likely future changes in the labour force.

66. The technique for projecting the labour force which has gradually come into general use involves the projection of trends in sex-age-specific activity rates and the application of these rates to the projected population in each sex-age group. In the simplest variation of this method, it is assumed that the sex-age-specific activity rates remain constant in the future at the levels observed in a recent census or survey; thus, all the changes shown in the labour force are due to the growth and changing sex and age composition of the population.<sup>86</sup> It has been observed, however, that in actuality these activity rates rarely remain constant, but rather follow certain typical patterns, at least in the case of males. It has, therefore, become increasingly common in preparing projections to allow for future changes in activity rates. Sometimes changes observed in age-specific activity rates between two dates in the past have been extrapolated by mathematical formulae.<sup>87</sup> Where comparable trend data are not available, target activity rates for the terminal date of the projection have sometimes been borrowed from another country, or group of countries, at a higher level of development, or from a more developed region within the country for which the projection is being prepared.<sup>88</sup> In some cases assumptions as to future changes in activity rates of particular age groups have been based on such factors as projected school attendance trends, prospective social measures affecting retirement, and in the case of women—judgements concerning probable changes in marital status and fertility or in social customs and

attitudes.<sup>89</sup> For certain countries quite refined projections have been prepared, including separate projections of the female labour force by marital status, and for women with and without young children.<sup>90</sup> Projections of the labour force have sometimes been made separately for urban and rural areas, in view of the markedly different patterns of labour force participation in these areas.<sup>91</sup>

67. More complex techniques of projecting activity rates by cohorts have been applied in some projections.<sup>92</sup> According to this method, age-specific activity rates for

<sup>89</sup> For example, the adoption of legislation establishing an additional obligatory school year, and new regulations concerning age at retirement, were among the factors taken into consideration in setting assumptions concerning future activity rates in projections prepared for Austria for the period to 1980. See Hansluwka, "Vorausberechnung der berufstätigen Bevölkerung Österreichs ..." (1964). In France, activity rates for persons under 25 years of age have been derived after first projecting trends of school attendance at each age. Calot *et al.*, *Projections démographiques pour la France* ... (1970), p. 36. See also France, Premier Ministre, *Les besoins en emplois nouveaux* ... (1961), pp. 17-20; Rogiers, "Les prévisions de la population active et de l'emploi ..." (1965). In projecting the female non-agricultural labour force in Poland it was assumed that the effects of factors tending to increase activity rates (for example, improvements in professional qualifications and a decline in fertility) would more than offset those tending to reduce participation (for example, a rise in school attendance and increase in the proportion married). Frenkel and Józefowicz, "Z badań nad prognozą ..." (1965). Other projections which allow for changing activity rates in certain sex-age groups in response to envisaged trends in socio-economic variables include: Tilak, "The future manpower situation in India ..." (1963); Bolle, "Bevölkerung und Arbeitskräftepotential ..." (1965); Organisation for Economic Co-operation and Development, *Demographic Trends 1965-1980* ... (1966); Bourgeois-Pichat, "Perspectives sur la population active européenne" (1953); and Fourastié, "La croissance des classes jeunes ..." (1956).

<sup>90</sup> For example, in preparing recent projections for the United States, trends in activity rates have been projected separately by marital status, and for married women with and without young children. See Travis, "The U.S. labor force: projections to 1985" (1970); Cooper and Johnston, "Labor force projections for 1970-80" (1965). In some other projections, constant activity rates have been assumed for different marital status categories. See New Zealand, Department of Statistics, *New Zealand Population and Labour Force Projections* ... (1968).

<sup>91</sup> This method was used in projecting the female labour force of the Philippines, and both the male and female labour force in the main working ages in Chile. See, respectively, United Nations, *Population Growth and Manpower* ... (1960); Sadie, "Población y mano de obra de Chile ..." (1969), pp. 39-40. For other applications see Jones, "A projection of the labour force in Malaya" (1967); and Chellawani, "Population trends and labour force in India ..." (1958). Trends in activity rates have sometimes been projected separately for more developed and less developed regions of a country. See the labour force projections for Czechoslovakia in Srb and Kučera, "Obyvatelstvo v produkčním ..." (1957).

<sup>92</sup> Cohort methods have been used, for example, in projecting the female labour force of the United Kingdom, the United States, the married female labour force of Australia, certain age groups of the female labour force in France, and the agricultural labour force in France. See, respectively, Beckerman and Sutherland, "Married women at work in 1972" (1963); Beckerman, "The future growth of national product" (1965); Durand, *The Labor Force of the United States* ... (1948); Australia, Commonwealth Treasury, *Projections of the Work-Force* ... (1965); Calot *et al.*, *Projections démographiques pour la France* (1970), pp. 38-39; and Febvay, "La population agricole française ..." (1956); Pressat, "La population agricole en France ..." (1957). Tabah has applied matrix calculation as a technical aid in projecting the labour force when a large number of variables which affect labour force size are to be taken into account. See his "Représentations matricielles de perspectives de population active" (1968).

(Footnote 85 continued)

females 15-59 years. Organisation for European Economic Co-operation, *Demographic Trends in Western Europe, 1951-1971* ... (1956).

<sup>86</sup> For examples of projections based on constant activity rates, see: Organisation for European Economic Co-operation, *Demographic Trends, 1956-1976, in Western Europe and in the United States* (1961); Netherlands, Centraal Bureau voor de Statistiek, "Berekeningen omtrent ..." (1961); Tunkelo, "Aktiivinen väestö vuosina 1951-71" (1957); Camisa, "Aspectos demográficos de la población económicamente activa ..." (1970); Strömmer, *Väestönkehitys ja työvoimavarat* ... (1959), pp. 70-72.

<sup>87</sup> See, for example, Durand, *The Labor Force in the United States* ... (1948), pp. 237-250; Bancroft, *The American Labor Force* ... (1958), pp. 176-182.

<sup>88</sup> See, for example, Livi Bacci and Pilloton, *Popolazione e forze di lavoro* ... (1968); Ducoff, *Human Resources of Central America* ... (1960), pp. 46-47; Elizaga, *Proyección de la población masculina* ... (1963), p. 5.

future dates are calculated from observed or estimated activity rates for the same cohort at an earlier date, with the amount of change in the activity rate of the cohort usually being estimated on the basis of past trends. Thus, the method has the advantage of taking into account the previous history of labour force participation of each cohort; this technique may be particularly useful for projecting female activity rates, since the likelihood of a woman's being in the labour force at an older age is related to her activity status at younger ages.<sup>93</sup>

68. Although they are not very common, further refinements have sometimes been made in projections of labour supply to take into account the interaction between activity rates and the general state of the economy, or the prospective demand for labour. In some developing countries where the supply of labour is expected to greatly exceed demand, conditions of unemployment and underemployment may discourage some marginal groups in the potential labour force from seeking work. On the other hand, in some developed countries where manpower shortages are foreseen for the future, the existence of plentiful job opportunities may stimulate an increase in activity rates among certain groups in the population. Labour force projections prepared for Belgium and the United States of America, for example, have taken into account expected trends in employment in the different sectors of the economy, and the assumptions regarding the participation rates of certain segments of the population have been modified in the light of the projections of labour demand.<sup>94</sup> In some socialist countries of Eastern Europe, special studies have been made of the characteristics of the inactive population so as to assess the reserves which might be drawn into the labour force to meet manpower demands.<sup>95</sup>

69. Until recently labour force projections were prepared mainly for individual countries to meet specific planning needs of governments. The last decade, however, has seen the development of a number of labour force projections for geographical groupings of countries, for major regions, and finally for the world as a whole.<sup>96</sup> The latter projections, while necessarily somewhat crude, call attention to outstanding features of manpower trends in major parts of the world and are useful for broad analyses of manpower problems. The most comprehensive of such projections have been those recently developed by the International Labour Office for the world and twenty-four geographical regions to the year 1985.<sup>97</sup> The

population projections used as a basis for the labour force projections are the United Nations medium projections as assessed in 1968.<sup>98</sup>

70. The projections of the labour force were based on estimated sex-age-specific activity rates for each country for 1950 and 1960. For countries lacking such data, values were estimated on the basis of patterns existing in the same geographical region or in selected countries in other regions having similar demographic, economic and social conditions. For projecting the activity rates to 1985, models were developed, based on analyses of labour force structure and activity rates in various countries at different points in time and at different stages of economic development. Thus, it was assumed that the activity rates for a particular country in the future would follow patterns of change observed in other countries at similar stages of their development.<sup>99</sup>

71. As shown in table XV.6, the world's total labour force was estimated at about 1,380 million persons in 1965; it may have risen to over 1,500 million by 1970 and may approach 2,000 million by 1985. In the fifteen-year period between 1970 and 1985, nearly 500 million persons are expected to be added to the world's labour force, according to these projections. The great bulk of this increase will be accounted for by the growth of population in the working ages. Expected changes in activity rates, which have less impact, will tend to reduce labour force numbers, as seen below. The validity of the labour force projections is thus greatly dependent on the projections of total population in the working ages.<sup>100</sup>

72. Of the projected increase of about 460 million in the world's labour force between 1970 and 1985, 375 million, or more than four fifths, is expected in the developing regions. The proportion of total labour force growth accruing to the developing regions is expected to show a rising trend, from 79 per cent in 1970-1975, to 83 per cent in 1975-1980, and 84 per cent in 1980-1985. This trend is explained by the fact that rates of labour force growth are expected to rise slightly in the developing regions and to decline slightly in the more developed regions.

73. The 1970s, designated as the Second United Nations Development Decade, may see an expansion of 285 million in the world's labour force—231 million in the developing regions, and 54 million in the more developed regions. Of these expected additions, 178 million are in Asia, 33 million in Africa, 26 million in Latin America, 18 million in the USSR, 15 million in North America,

and some principal regions to the year 1975 appeared in International Labour Office, "Projections of population and labour force" (1961).

<sup>98</sup> United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

<sup>99</sup> International Labour Office, *Labour Force Projections ...* (1971), part V, pp. 4-6. For a more detailed description of the methodology see ———, *Labour Force Projections ...* (1971), part VI.

<sup>100</sup> It may be noted that short-run projections of working age population depend only on mortality trends (except where migration is an important consideration), since the age groups concerned are the survivors of cohorts already born at the time of preparation of the projections. Projections for longer periods in the future are more subject to error, since they are affected by the assumptions of future fertility trends which are more difficult to estimate.

<sup>93</sup> For arguments supporting a cohort approach to projecting the economically active female population, see Dubrulle and Gontier, "Les désirs d'activité professionnelle des femmes mariées chargées de famille" (1969).

12 million in Europe and 2 million in Oceania. Such figures give a rough indication of the numbers of new employment opportunities which will be required to absorb additions to the labour force.

74. While these increases in labour force numbers appear very great, it is to be noted that the growth in the labour force has been lagging behind the growth in population. Thus, whereas the world's total population is estimated to have been increasing at about 2.0 per cent annually during the latter half of the 1960s,<sup>101</sup> the corresponding rate for the labour force was only 1.7 per cent. If the declines in fertility which have been assumed to begin in many developing regions in the 1970s occur, the changes in age structure which follow will result in a narrowing of the gap between the rate of labour force and total population growth. Thus, the projections show the total population growth rate for the world as a whole stabilized at 2.0 per cent in the period to 1985, while the rate of growth of the labour force would rise to 1.9 per cent annually by 1980-1985.

75. The world pattern, as described, largely reflects the main features of trends in the less developed regions, where the labour force growth rate is shown to rise from 2.0 per cent annually in 1965-1970, to 2.1 per cent in 1975-1980, and 2.2 per cent in 1980-1985. On the other hand, the total population growth rate in these regions shows a slight decline from 2.5 per cent annually in 1970-1975 to 2.4 per cent during 1980-1985. A decline in the labour force growth rate can be expected only some fifteen years after the onset of fertility decline, when the smaller birth cohorts reach working age.

76. In contrast to the high rates of growth shown for the developing regions, the labour force is expected to grow at only about 1.0 per cent annually in the developed regions—a trend closely paralleling that of the total population. The very low rate of growth of Europe's labour force—0.5 to 0.6 per cent in 1970-1980 is particularly striking.

77. Table XV.7 shows the projected trend of the male and female age-specific activity rates in the developing

TABLE XV.7. PROJECTIONS OF AGE-SPECIFIC ACTIVITY RATES FOR MALES AND FEMALES, FOR THE WORLD'S DEVELOPING AND MORE DEVELOPED REGIONS: 1960-1980

Region, sex and age (years)	1960	1970	1980
Developing regions

<sup>101</sup> See table XV.1.

and more developed regions of the world. A downward trend in activity rates is shown for school-age youths and for older workers of both sexes. The age groups mainly affected are those under 20 and 65 years and over in both the developing and developed regions. The projected decline in activity rates for young persons anticipates the greater emphasis on education in national development policies, including the extension of compulsory education and longer average duration of schooling at all levels in response to the growing demand for better educated and more highly trained workers. The projected decrease in activity rates of the older workers, on the other hand, anticipates a continued expansion of social security coverage and retirement schemes, as well as declines in the relative importance of agriculture in the course of economic development.

78. For women between 25 and 54 years of age, projected trends in activity rates differ in the developing and more developed regions. In the latter, a further modest rise in activity rates is shown, whereas a decline appears in the activity rates in the developing regions, apparently resulting from the expected continuation of the shift away from agricultural employment and the consequent curtailment in the numbers of unpaid family workers.

## 2. URBAN AND RURAL POPULATION

79. The demand for urban and rural population projections has become progressively more intense in recent years. Economists, sociologists, business firms, public administrators, and planners find increasing need for urban and rural projections in theoretical analyses of economic and social development as well as in a wide diversity of practical applications.<sup>102</sup> Urban and rural projections are essential for the efficient planning of future investments by both governments and enterprises. Very often such projections are required in considerable detail at subnational levels. A review is made below of some of the types of methods and assumptions which have been used in developing urban and rural projections. Finally, some United Nations projections of urban and rural population in world regions and major areas are provided to illustrate broad trends which may be expected in both the developing and the developed regions.

80. The techniques currently used to project urban and rural population may be classified as either demographic or extrapolatory.<sup>103</sup> In demographic approaches, explicit consideration is given to the three components of demographic change (fertility, mortality and migration) in both urban and rural sectors. Since the calculations are usually made by individual sex and age groups, the final presentation of results will generally include sex and age detail for both the urban and the rural population at

future dates. In extrapolatory approaches, the basic calculations are more often made on the basis of data for total urban and rural population and the results include only urban and rural totals at future dates. However, various prorating techniques have come into use by which sex and age compositions can be derived from the projected urban and rural totals.<sup>104</sup> A fourth source of change, the reclassification of rural localities as urban, as discussed above, must also be considered.

81. In demographic approaches, the estimation of total population is often aggregative; that is, the urban and rural population are projected independently and the total population is then obtained as the sum of the projected urban and rural populations. Sometimes, however, it may happen that information pertaining to the rural sector is insufficient for the purposes of projections. In such cases, the urban population may be projected by demographic techniques and the rural population obtained by subtraction of the urban population from a previous projection of the total population.

82. In extrapolatory projections, the approach is usually distributive rather than aggregative. A previous projection of total population is accepted at the outset as given, and the projection of urban and rural population is derived from a projection of the future distribution of the total population between its urban and rural segments. Such projections may be based upon assumptions relating to the future rise in the percentage of urban population or on assumptions relating to the relative growth rates of the total population and its urban and rural sectors. In these approaches, the underlying factors of fertility, mortality, migration and urban reclassification are not explicitly considered.

83. Projections of urban and rural population by demographic techniques have been based on a variety of assumptions concerning future trends in each of the demographic components of change.<sup>105</sup> The most sophisticated approach is the cohort-component (cohort-survival) method. This technique is used in countries where sufficient data are available, though there are wide differences in the formulation of assumptions with regard to fertility, mortality, and migration.<sup>106</sup> Urban-rural differentials with respect to both fertility and mortality are generally greater in the developing countries than in the more developed countries. In many developed countries where low over-all mortality rates prevail, the error stemming

<sup>104</sup> See, for example, Grauman, "Population estimates and projections" (1959), pp. 567-569; United Nations, *Population Growth and Manpower* ... (1960); Benítez Zenteno and Cabrera Acevedo, *Proyecciones de la población de México 1960-1980* (1966); and Cataldi, D., *La situación demográfica del Uruguay* ... (1964).

<sup>102</sup> For example, it has been suggested that the distinction between urban and rural areas is so fundamental in population projections that it would be desirable to retain the urban-rural classification, whenever possible, not only in projections of total population but also in projections of labour force, school-age population and school attendance, population by educational level, and households and families. United Nations, *General Principles for National Programmes* ... (1965), pp. 4-5.

<sup>103</sup> A survey of techniques in current use is available in Siegel, "Some principles and methods of projections ..." (1967).

<sup>105</sup> The following are examples of projections made by demographic techniques: Hartman, *Alueellinen väestö* ... (1964); Roberts, "Provisional assessment of growth ..." (1963); Greece, Hypourgeion Syntonismion, *Demographikai exeliseis en Helladi* ... (1962); Pallós, "Területek népességének távlati alakulása ..." (1966); Podyachikh, "Population projections in which allowance ..." (1967); United States of America, Bureau of the Census, *Projections of the Population of Metropolitan Areas: 1975* (1969); Silverio, *Proyecciones de la población urbana y rural de Venezuela* ... (1964); and various other monographs in Series C of the Centro Latinoamericano de Demografía.

<sup>106</sup> Conference of European Statisticians, *Methods and Uses of Projections of Urban and Rural Populations* ... (1971), pp. 5-6.

from the use of the average national mortality pattern in both the urban and the rural component projections is relatively small<sup>107</sup> and such an approach can often be justified.<sup>108</sup> Rather little is known about urban-rural mortality differentials in the developing countries. The studies reviewed in chapter V, section E, suggest that, on balance, mortality is likely to be somewhat higher in rural than in urban areas, owing mainly to the greater concentration of medical facilities and health services in the latter.<sup>109</sup> Moreover, in rural areas characterized by dispersed or very small village settlements, the peasant may be unable to take proper precautions with regard to drinking water and sanitation. In isolated areas, the peasant population may be subjected to the ravages of sickness and disease caused by drinking foul water and the absence of sanitation facilities.<sup>110</sup>

84. In developed countries, as shown in chapter IV, section F, fertility has generally been found to be higher in rural than in urban areas, although the differences have narrowed since the Second World War. Evidence concerning urban and rural differentials in the developing regions is less clear and there is need for controlled studies using comparable standards of measurement. In Latin America, at least, it has been rather well confirmed that rural fertility is higher than urban fertility by any standard of measurement.<sup>111</sup>

85. The problem of developing projection assumptions with regard to fertility has been approached in several ways. Although rather complex experimental techniques have been tried in some European countries where data are good,<sup>112</sup> relatively less complicated methods have more often been utilized in actual practice. One of the procedures followed in estimating expected fertility trends is to develop projection assumptions by comparing the past trends of rural and urban populations with the over-all fertility trends of the country. This can be done

<sup>107</sup> See, for example, evidence reviewed in chapter V, section E.

<sup>108</sup> This approach has previously been used in some European projections. *Ibid.* It has also been used in projections for the United States of America. See United States, Bureau of the Census, *Projections of the Population of Metropolitan Areas: 1975* (1969). In recent Soviet projections, however, separate sets of survival ratios were applied in the urban and rural projections. Pobedina, "The use of electronic computers for population projections" (1967).

<sup>109</sup> In addition to the sources cited in chapter V, see also Arriaga, "Components of city growth ..." (1968), pp. 244, 250. In many developing countries under-registration of deaths may be more severe in rural than in urban areas.

<sup>110</sup> Dickinson, *The Population Problem of Southern Italy ...* (1955), p. 24. See also the discussion in Benko, "Rural planning in Poland" (1966), pp. 370-381, concerning the difficulties encountered in providing services and utilities, including water supply and sanitation, to small rural villages.

<sup>111</sup> Carleton, "Fertility trends and differentials in Latin America" (1965).

<sup>112</sup> Such as extrapolation of urban and rural age-specific rates by means of analytical trends or graphic methods; age-specific rates derived from levels of gross reproduction rates projected separately for urban and rural areas; or derivation of assumed age-specific fertility rates on the basis of detailed analyses of past and present fertility patterns and levels in urban and rural areas. Sometimes survey data concerning the intentions of married couples with regard to the future number of children which they desire or expect are taken into consideration. See Conference of European Statisticians, *Methods and Uses of Projections of Urban and Rural Populations ...* (1971), p. 7.

by means of the general fertility rate,<sup>113</sup> but somewhat better results were obtained in European countries with the use of age-specific rates.<sup>114</sup> The convergence or divergence of the trends can provide valuable information in predicting future urban-rural fertility differentials, especially if coupled with careful socio-economic analysis.

86. Special problems arise in connexion with the fertility behaviour of rural-to-urban migrants, particularly in areas where the level of rural-to-urban migration is rather high.<sup>115</sup> In recent projections for the Soviet Union, it was assumed that the fertility of rural-to-urban migrants would be similar to the fertility of the existing urban population, which was generally lower than the fertility of the rural population in the same area.<sup>116</sup> The projected total population computed under these assumptions was appreciably lower than it might have been according to a distributive projection. However, it was later observed in the Soviet Union that the birth rate among rural-to-urban migrants is actually higher than it is for native urban residents. Moreover, it was found that a substantial part of the natural increase in the urban population is provided by migrants from rural areas.<sup>117</sup> No general conclusions were drawn from the studies reviewed in chapter VI, section B, as to how the fertility of rural-urban migrants is likely to differ from that of the native urban population. Some of these studies showed higher fertility among migrants than among natives; others showed lower fertility among the migrants; and still others showed no significant difference. It is clear that the selection of projection assumptions with regard to the fertility of rural-to-urban migrants calls for careful evaluation of available evidence in the light of the unique circumstances prevailing in any individual country. There is need for more controlled studies which take into consideration possible differences in the age-specific fertility patterns of rural-to-urban migrants and urban natives and also fertility differences by length of stay in cities. Some further discussion of these issues appears in chapter VI, section C.

87. Where knowledge of detailed urban-rural mortality and fertility differences is lacking, it has sometimes been assumed that the crude rate of natural increase (the

<sup>113</sup> Such an approach was followed in United States projections for metropolitan areas. The general fertility rate was determined for each area by comparison with the national rate. It was then assumed that the factors producing fertility differentials between the areas would gradually disappear within fifty years, and that by the year 2010, each area's general fertility rate would be equal to the national rate. Starting with each area-national ratio in 1960 and assuming the ratio will reach unity by 2010, the ratios for the intermediate years to 1975 were obtained by linear interpolation. United States of America, Bureau of the Census, *Projections of the Population of Metropolitan Areas: 1975* (1969), pp. 7-8.

<sup>114</sup> Both approaches have been used in Europe. See Conference of European Statisticians, *Methods and Uses of Projections of Urban and Rural Populations ...* (1971), p. 7.

<sup>115</sup> *Ibid.*, pp. 14-16.

<sup>116</sup> Podyachikh, "Population projections in which allowance ..." (1967). Also Pobedina, "The use of electronic computers for population projections" (1967). It was also assumed in the calculations that when a community is reclassified from the rural to the urban category its reproduction rate changes at the same time from rural to urban.

<sup>117</sup> Perevedentsev, "Migratsiia naseleniia ..." (1970), p. 34.

excess of the crude birth rate over the crude death rate) may be approximately equal in both urban and rural areas.<sup>118</sup> This approach was taken in recent projections of urban and rural population in Morocco and Tunisia.<sup>119</sup> Some supporting evidence with regard to this issue can be found in chapter VI, section C.

88. The question of migration assumptions is the most difficult problem with regard to urban and rural projections. Age composition is an obvious consideration, as the motivations which underlie rural-to-urban migration are related to occupational, educational, and other socio-economic factors which are selective by age. But the particular nature of the age-selective process varies greatly among areas and also within a single area over time. There is also the very great problem of distinguishing between permanent and temporary rural-to-urban migration, and the definition of the permanent and temporary categories varies from country to country. In view of the difficulties in forecasting the number and composition of migrants, the assumptions taken with regard to migration for urban-rural projections are often rather mechanical.<sup>120</sup> Net rural-to-urban migration trends are sometimes assumed to remain stable at a given level, which is usually that of an average level at the starting date of the projection period. This approach may be appropriate in some countries where levels of urbanization are not as yet high. In countries where recent data show a diminishing trend of rural-to-urban migration, these trends are sometimes projected into the future. In this approach, the age composition of migrants is usually assumed to be constant. In other countries, especially in those countries where the level of urbanization is already high, the net rural-to-urban migration rates are assumed to decrease, gradually approaching the zero level.<sup>121</sup>

89. Where statistics are deficient, it is sometimes not unreasonable to assume that the number of future migrants from rural to urban areas will be in a constant ratio to the level of natural increase in rural areas. In other words, rural population excesses resulting from annual additions through natural increase may be offset in some degree by a compensating pattern of annual departures by rural inhabitants to urban settlements. Such an approach was used in projections for Tunisia.<sup>122</sup> A few examples of the ratio between rural out-migration and rural natural increase in different areas are discussed in chapter VI, section C.

<sup>118</sup> A discussion of the relative contributions of natural increase and migration to urban growth appears in chapter VI, section C.

<sup>119</sup> See Dubois, "Essai de perspective démographique pour le Royaume du Maroc" (1959); and Seklani, "Villes et campagnes en Tunisie ..." (1960).

<sup>120</sup> Conference of European Statisticians, *Methods and Uses of Projections of Urban and Rural Populations* ... (1971), p. 12.

<sup>121</sup> Such approaches have been used upon occasion in European countries, Conference of European Statisticians, *Methods and Uses of Projections of Urban and Rural Populations* ... (1971), p. 12. Migration assumptions based on past trends have been used in United States projections. See United States of America, Bureau of the Census, *Projection of the Population of Metropolitan Areas: 1975* (1969).

<sup>122</sup> Seklani, "Villes et campagnes en Tunisie ..." (1960), pp. 507-511. Alternative projections were made by projecting two different ratio constants.

90. In centrally planned economies, the level of urban migration can be estimated by reference to the number of planned or expected job opportunities in cities. Recent projections of urban and rural population for the Soviet Union have been based upon regional development plans. The volume of migration for the period covered by the projections was determined by the planning agencies on the basis of the plans for the distribution of productive investments and the plans for supplying the corresponding manpower.<sup>123</sup> By contrast, in developing countries where the scope of planning is still limited, the flow of migrants to cities often far exceeds the actual number of urban employment opportunities.

91. In contrast to the demographic projection approaches discussed thus far, the extrapolatory approaches do not utilize separate assumptions concerning fertility, mortality and migration.<sup>124</sup> The ratio method is one of the most frequently used extrapolatory techniques.<sup>125</sup> In this approach, the percentage of urban population is projected to increase according to some schedule which may be derived by extrapolation of past trends or by analogy with the experience of other countries. The rural population is then obtained as a residual. If projections of labour force engaged in agriculture are available, it is sometimes possible to project the percentage of rural population by assuming some relationship between the percentage of population residing in rural areas and the percentage dependent on agriculture. The urban population is then obtained as a residual.<sup>126</sup>

92. A variety of growth rate assumptions may be used as a basis for simple extrapolatory projections of urban and rural population. Depending on circumstances prevailing in individual countries, there may be reason to believe that fairly accurate projections can be obtained by assuming a constant rate of growth of urban population based on past experience, with the rural population obtained as a residual; or conversely, by assuming a

<sup>123</sup> Podyachikh, "Population projections in which allowance ..." (1967).

<sup>124</sup> Extrapolatory techniques were used, for example, in the following sources: Benítez Zenteno and Cabrera Acevedo, *Proyecciones de la población de México 1960-1980* (1966); Chasteland, *Projections de la population de Téhéran* (1966); Etherington, "Projected changes in urban and rural population in Kenya ..." (1965); United Nations, Economic Commission for Latin America, *Statistical Bulletin for Latin America*, vol. 2, no. 2 (1965), pp. 9, 199-200; Centro Latinoamericano de Demografía, *Boletín demográfico*, año 2, vol. 3 (1969), pp. 3, 8-9; Hama, "Kinki 6-fuken ni okeru ku-shi-cho-son ..." (1967); and his "Nihon jinko no zoka ..." (1970); Pickard, *Metropolitanization of the United States* (1959); Gómez Barrantes, *Estimaciones de población para Costa Rica* ... (1967); United Nations, *Population Growth and Manpower* ... (1960); ———, *World Housing Conditions and Estimated* ... (1965); United Nations, Economic Commission for Asia and the Far East, "Population growth and problems of employment ..." (1961); Venezuela, Oficina de Análisis Demográfico, *Proyección de la población urbana y rural de Venezuela* ... (1964).

<sup>125</sup> Applications of the ratio method in urban and rural projections can be found in the following sources: Davis, *World Urbanization 1950-1970, vol. 1: Basic Data* ... (1969); Gómez Barrantes, *Estimaciones de población para Costa Rica* ... (1967); Zobel, *Proyecciones de población para la República de Guatemala* ... (1967).

<sup>126</sup> This approach was used in United Nations, *Population Growth and Manpower* ... (1960); and Ducoff, *Human Resources of Central America* ... (1960).

<sup>a</sup> Urban population defined as that of "densely inhabited districts" according to the census.

constant rate of rural population growth and obtaining the urban population as a residual. Recent projections in Kenya have been made by assuming a constant urban growth rate.<sup>127</sup> The constant rural growth rate technique was followed in recent projections for Mexico and for many other Latin American countries.<sup>128</sup>

93. Recent United Nations projections of urban and rural population to the year 1985 are shown in table XV.8.<sup>129</sup> According to these projections, the world will

<sup>127</sup> Etherington, "Projected changes in urban and rural population in Kenya ..." (1965).

<sup>128</sup> Benítez Zenteno and Cabrera Acevedo, *Proyecciones de la población de México 1960-1980* (1966); United Nations, Economic Commission for Latin America, *Statistical Bulletin for Latin America*, vol. 2, no. 2 (1965), pp. 9, 199-200; Centro Latinoamericano de Demografía, *Boletín demográfico*, año 2, vol. 3 (1969), pp. 3, 8-9.

<sup>129</sup> A modification of the growth rate techniques was used in these projections. It was assumed that the difference between the urban growth rate and the rural growth rate would remain constant. For many countries the growth rate difference of the base period (1950-1960 and 1960-1965 depending on the available data) was

be about 44 per cent urban by the year 1985 (table XV.9). There will, of course, remain large differences in the level of urbanization among major areas of the world. Europe, Latin America, Northern America, Japan and the USSR will probably all be more than two thirds urban. Australia-New Zealand will be nearly 90 per cent urban. By contrast, Africa and Asia will be only about one third urban.

94. Although the level of urbanization in Africa and Asia is still quite low, these areas will, nevertheless, contain substantial urban populations. Asia alone may contain an urban population of close to 1,000 million, or more than 40 per cent of the world's urban population in 1985. By that date Asia's urban population is projected to be nearly as great as the urban population of the entire world in 1960.

projected into the future. In other countries an alternative growth rate difference was assumed on the basis of comparison with other countries. For earlier United Nations projections of urban and rural population see United Nations, *Growth of the World's Urban and Rural Population ...* (1969).

SOURCE: Based on United Nations, *Monthly Bulletin of Statistics*, November 1971 (1971), table B-II.

<sup>a</sup> Urban population defined as that of "densely inhabited districts" according to the census.

95. The highest growth rates of urban population have been calculated for Africa, Asia, and Latin America. Annual rates of urban growth between 4 and 5 per cent per year are expected for Asia and Latin America throughout the projection period and rates around 5 per cent are expected for Africa. By contrast, the annual rates of urban growth expected during the various decades of the projection period are only about 2 per cent for Northern America and 1.5 per cent for Europe.

96. The share of the world's rural population that will probably be claimed by Africa and Asia is even more overwhelming than the very large share of urban population in these areas. Whereas Africa and Asia together may contain about half of the world's urban population by 1985, these areas will probably contain more than 80 per cent of the world's rural population. The rural population in Africa and Asia is expected to continue growing by substantial amounts, while absolute declines are expected in the rural population of Europe, the USSR, Northern America and Japan in all decades of the projection period.

### 3. AGRICULTURAL POPULATION<sup>130</sup>

97. Since agriculture constitutes the largest sector of the economy in most developing countries, estimates and projections of the agricultural population are essential for the preparation of development plans. Such data are needed specifically for calculating the *per capita* gross domestic product arising from agriculture—an important indicator of the degree of agricultural development. Moreover, these data provide the basis for calculating requirements for food and other agricultural commodities in the agricultural segment of the population, and hence, for deriving estimates of the marketable surplus of agricultural products.

98. Most European countries obtain information in their population censuses on the population dependent on the different branches of economic activity, and thus

<sup>130</sup> Unless otherwise noted, the discussion in this section is drawn from Food and Agriculture Organization of the United Nations, "Methods and assumptions for projections of agricultural population" (1969).

TABLE XV.10. PROJECTIONS OF POPULATION DEPENDENT ON AGRICULTURE FOR MAJOR AREAS OF THE WORLD: 1965-1985

SOURCE: Data provided by the Food and Agriculture Organization of the United Nations. For a different regional classification of these projections, see Schulte, Naiken and Bruni, "Projections of world agricultural population" (1972).

Note: The totals for the world, developing and more developed regions have been adjusted to take into account discrepancies between international immigration and emigration assumptions.

obtain a direct measure of the agricultural population, consisting of persons economically active in agriculture and their dependants.<sup>131</sup> Such census data are, however, much less frequently available for countries in other continents.

99. Owing to the paucity of data on the agricultural population, it is often necessary, before preparing projections of agricultural population, to estimate the size of this population in the base year. This step is particularly required in preparing world and regional projections, since estimates prepared on a common base are needed for all countries, including those for which census data are lacking or deficient.

100. There are three principal means of obtaining such estimates: (a) from the information on farm population collected in agricultural censuses; (b) based on the ratio of agricultural labour force to the total labour force; and (c) based on observed variations of the ratio between agricultural and rural population in certain countries at different stages of economic development.

101. With respect to the first method, the few data available on both farm population and agricultural population suggest that, for the developed countries at least, there are considerable differences between the two. On the other hand, these differences appeared to be somewhat less for the few developing countries for which comparisons could be made. In applying the second method, it is usually assumed that the ratio of agricultural population to total population is equal or nearly equal to the ratio of the agricultural labour force to the total labour force. These two ratios will, of course, be equal if the dependency ratio in the agricultural sector is equal to that in the non-agricultural sector. Available data indicate that the difference between these two dependency ratios is not large, particularly in developing countries. The third method derives from the observation that the ratio of agricultural population to rural population is

inversely related to the level of economic development, as measured by *per capita* income. Data for a limited number of countries suggest that this ratio tends to fall between 20 and 50 per cent in high-income countries, 70 to 100 per cent in low-income countries and 50 to 70 per cent in countries at an intermediate income level.

102. One obvious method of projecting the agricultural population involves the extrapolation of past trends, but there are only a few countries for which the needed data are available in reliable form. Furthermore, such a procedure implies that future economic development in the agricultural sector will follow the same pattern as in the past, an assumption not consistent with the increased efforts of governments toward economic development.

103. A second method is to base the projections of agricultural population on past trends in the rural population, which are available for a larger number of countries. Simple extrapolation of past trends in the rural population can be expected to lead to over-estimates, however, since rural population may grow somewhat less rapidly than in the past, and the ratio of agricultural to rural population is likely to decrease with economic development. The Food and Agriculture Organization of the United Nations (FAO) has attempted to work out correction ratios which could be applied, based on analyses of observed decreases in the rate of growth of rural population, and in the ratio of agricultural to rural population, in countries that have already experienced such trends.

104. A method which FAO has used extensively is that of linking the projections of agricultural population with those of the agricultural labour force, since, as noted above, the ratio of the agricultural population to the total population appears to be closely correlated with the ratio of agricultural labour force to total labour force. Therefore, projections of the latter ratio may provide a reasonable basis for projecting the agricultural population. This method has been used in preparing a recent set of projections of agricultural population, the results of which for the world and major regions are summarized in table

<sup>131</sup> For a discussion of some of the problems of measuring the agricultural population see Dovring, "Labor force composition..." (1964), p. 34.

XV.10.<sup>132</sup> The projections of agricultural population were closely linked with projections of the economically active population in agriculture prepared by the International Labour Office.

105. The preparation of agricultural population projections on a national basis has been confined to a few developed countries. Some of these projections have been derived by more refined techniques than those discussed above, based on probable future trends in factors which influence the size and distribution of the agricultural population, for example, taking into account labour requirements by the size of holdings in relation to cultivation patterns and techniques of agricultural production.<sup>133</sup> The world-wide set of projections prepared by FAO, however, has necessarily had to rely on simpler techniques.

106. Table XV.10 presents projections of agricultural population for the major areas of the world from 1965 to 1985.<sup>134</sup> The table indicates the anticipated downward trend in the percentage of the agricultural population, particularly in the more developed regions. More important, however, is the anticipated increase in the total agricultural population in the less developed countries which is expected to take place despite the downward trend in its percentage of total population. According to the projections, the less developed regions can expect their agricultural population to increase by 214 million, or 13 per cent, during the decade of the 1970s, while the more developed regions would have a decrease of 27 per cent during the same period. This increase in the less developed regions, though considerably slower than that of their total population, derives its significance from the fact that it will take place in the sector of the population that is poorest, least educated, and living under the least advantageous health conditions.

#### 4. EDUCATION

107. In addition to estimates of future school-age population which are provided by projections of total population by sex and age, the development of educational planning, in recent years particularly, has indicated the need for more detailed and comprehensive educational projections which include school enrolment and output

by level and type of education and projections of total population by educational attainment.

108. Various countries have made projections of educational enrolment and output, either within the framework of educational planning or in other contexts such as comprehensive and regional development plans and human resources plans. Very detailed educational projections are made in countries with centrally planned economies.<sup>135</sup> Projections of enrolment and output are also common phenomena in other developed countries.<sup>136</sup> In some developing countries work of this type has gradually been expanding.<sup>137</sup> Projections of school-age population and school attendance are part of a comprehensive study on population and manpower growth in the Philippines (1957-1977).<sup>138</sup> A similar study also was made for Central America and Mexico.<sup>139</sup> Projections for various Latin American countries prepared at the Latin American Demographic Centre (CELADE) concentrate mainly on the school-age population and enrolment in the first and second levels of education, though for some countries projections of university graduates, requirements for teachers and classrooms, and expenditures per pupil are also included.<sup>140</sup>

109. A frequent approach in enrolment projections is to extrapolate past trends in enrolment rates and apply the projected rates to a projected sex-age distribution of the population.<sup>141</sup> In some instances, enrolment rates have been projected on the basis of analytic studies relating changes in enrolment rates to changes in other socio-economic variables. Changes in socio-economic composition may be allowed for, to some extent, by separate projections of rates for the component categories, such as urban and rural population.<sup>142</sup>

110. There are several regional experiments in educational planning which include a variety of projections. One is the African Educational Development Programme sponsored by the African Governments and UNESCO.<sup>143</sup>

<sup>135</sup> Nozhko, *Methods of Estimating the Demand for Specialists* ... (1964).

<sup>136</sup> Belgium, Conseil National de la Politique Scientifique, *Rapport sur la croissance des populations étudiantes* (1961); Borrie and Dedman, *University Enrolments in Australia* ... (1957); Watson, Quazi and Kleist, *Ontario Secondary School Enrollment Projections* ... (1970); Pressat, "Croissance des effectifs scolaires ..." (1958); United States of America, Bureau of the Census, *Summary Demographic Projections* (1968).

<sup>137</sup> See, for instance, Nadarajah, *Projections of the School-Going Population of Ceylon* ... (1961); Khan, "A demographic approach to educational planning in Pakistan" (1969); Amine-Zadeh, "Impact de la croissance démographique en Iran ..." (1967).

<sup>138</sup> United Nations, *Population Growth and Manpower* ... (1960).

<sup>139</sup> Ducoff, *Human Resources of Central America* ... (1960).

<sup>140</sup> For examples of different kinds of projections see Peláez and García, *Panamá* ... (1965); Gutiérrez Roldán, *Proyección de la población de Chile* ... (1963); Mellon, *La enseñanza primaria en la República Dominicana* ... (1966); and Centro Latinoamericano de Demografía, *República de Guatemala, Volumen 1* ... (1965), pp. 47-67. Some of the projections were prepared separately for urban and rural areas.

<sup>141</sup> See, for instance, UNESCO, *Projections à long-terme de l'éducation au Laos* (1965).

<sup>142</sup> United Nations, Economic Commission for Latin America, *Some Aspects of Population Growth in Colombia* (1962).

<sup>143</sup> United Nations, Economic Commission for Africa and UNESCO, *Final Report, Conference of African States* ... (1961).

<sup>132</sup> Food and Agriculture Organization of the United Nations, data to be published.

<sup>133</sup> Projections of the agricultural population of Sweden to 1980 have been based on some of these considerations. See Norborg, *Jordbruksbefolkningen i Sverige* ... (1968), pp. 228-229. For recent projections of the agricultural population of France see Locoh, "La population des ménages agricoles ..." (1970); for earlier projections of the male agricultural population see Febvay, "La population agricole française ..." (1956). Projections of the agricultural labour force, which often serve as a basis for projections of agricultural population, have been prepared, for example, by Pressat, "La population agricole en France ..." (1957).

<sup>134</sup> Earlier projections of agricultural population to 1985 for specific developing regions appear in Food and Agriculture Organization of the United Nations, *Provisional Indicative World Plan* ... (1970), p. 23; for projections to the year 2000 for some of these regions see Organisation for Economic Co-operation and Development, *The Food Problem of Developing Countries* (1968), p. 70. Concerning future prospects of agricultural population in developing regions, see also Dovring, "The share of agriculture in a growing population" (1959).

TABLE XV.11. PROJECTIONS OF SCHOOL ENROLMENT IN THE ECAFE REGION, <sup>a</sup> 1964-1980

Level of education	1964	1970	1975	1980

SOURCE: UNESCO, *An Asian Model of Educational Development* ... (1966), table 19.

<sup>a</sup> Countries participating in the "Karachi Plan" (see text). Included are Afghanistan, Burma, Cambodia, Ceylon, China (Taiwan), India, Indonesia, Iran, Republic of Korea, Laos, Malaysia, Mongolia, Nepal, Pakistan, the Philippines, the Republic of Viet-Nam, Singapore and Thailand.

<sup>b</sup> Enrolment as a percentage of corresponding age groups, that is, first level, ages 6 to 12; second level, ages 13 to 17; third level, ages 18 to 21.

A similar programme initiated in Asia<sup>144</sup> (referred to as the "Karachi Plan") stimulated studies and educational projections which resulted in the preparation by UNESCO of the comprehensive study known as the "Asian model".<sup>145</sup> It attempted to visualize in quantitative terms the prospects of educational development until 1980, to illustrate the interrelationship of the main factors involved in educational development, and, finally, to draw attention to the important implications for educational development that become evident when specific data are examined systematically and quantitatively. The model covers a wide variety of aspects of educational developments. Besides projections of school enrolment and output (by grades), teacher stock and requirements, and enrolment in teacher-training institutions, it deals also with literacy and adult education and the financial implication of this projection. Countries participating in the Karachi Plan were divided into three groups, taking into account their actual and projected demographic, educational, economic and social conditions. School enrolment projections for the combined groups of countries are shown in table XV.11.

111. Projections of population by educational achievement or categories relevant to manpower requirements are confined mainly to developed countries. An example is the projection of educational levels of the Italian

population, worked out by SVIMEZ (Associazione per lo Sviluppo dell'Industria nel Mezzogiorno). The study gives a set of demographic projections related to anticipated growth of the economy and education. Among other aspects the projection covers (a) population by sex and age; (b) labour force by sex and age; (c) occupational structure of the labour force and (d) student population and educational output.<sup>146</sup>

112. Elaborate educational projections have also been made by the Organisation for Economic Co-operation and Development (OECD). These projections are part of the comprehensive studies and projections aimed at assessment of future requirements in manpower in relation to anticipated economic development. One OECD regional study was the Mediterranean Regional Project, which included educational projections for 1960-1975 for the six countries of Greece, Italy, Portugal, Spain, Turkey and Yugoslavia.<sup>147</sup>

113. As is evident even from this brief review, considerable progress has been achieved in the development and application of methods for making educational projections. In this process the work of UNESCO has played an important role of leadership in developing

<sup>144</sup> UNESCO, *Final Report, Meeting of Ministers* ... (1963).

methodological manuals,<sup>148</sup> and in the preparation of country and regional studies.

114. Educational planning will undoubtedly increase the demand for educational projections in forthcoming years and there is clearly a need to further develop methodology in this field. Among the questions calling for research are those pertaining to the influence upon enrolment of the labour force status and the family status of the individual and the relationship between rates of enrolment in higher education and the educational and occupational status of parents.<sup>149</sup>

115. There is also a need for developing the cohort approach to enrolment projections, which would give entries and separations along with the projected enrolment, by age and sex. The development of accession and withdrawal probabilities and of "tables of school life" should facilitate the application of this method. The future distribution of the population by educational attainment is obviously correlated with the future occupational pattern and it will be useful, therefore, to pursue the study of educational and training requirements for workers belonging to different occupations.<sup>150</sup>

116. It is widely accepted that educational projections cannot be merely extrapolations of past trends, but that they need to reflect changes resulting from new requirements and educational goals. While, as mentioned above, this makes the task of preparing educational projections much more complex, it contributes to making such projections more viable and responsive to the real and emerging conditions in both the developing and developed countries.

## 5. HOUSEHOLDS AND FAMILIES

117. A growing number of countries have found it desirable to have projections of the number of households or families, since they, rather than individuals, are the primary units of consumption, and information on their numbers and characteristics has great relevance for many kinds of economic and social planning. Examples include the fields of housing and social welfare. Around 1970, projections of households or families had been prepared for at least twenty-three countries.<sup>151</sup> In the United States of America, for example, the first series of household projections were prepared in 1937,<sup>152</sup> and new

projections have regularly been made whenever new data from a census or national sample survey became available.

118. For fifteen of the twenty-three countries, household projections have been prepared by the "headship rate" method,<sup>153</sup> while for the remaining eight countries, either simple mathematical extrapolation,<sup>154</sup> or highly complex methods—for example, employing various multi-decremental life tables—have been used.<sup>155</sup> The "headship rate" method is the one most widely used in developed countries having the required statistical data. As explained in chapter X, the "headship rate" denotes a ratio of the number of heads of households or families, classified by sex, age and sometimes by marital status, to the corresponding categories of population. In projections based on this method, headship rates for the population categories mentioned above are often assumed to remain constant,<sup>156</sup> although it is realized that for many regions, changing rates would present a more realistic picture of future trends.<sup>157</sup> To obtain the household or family projections, projected headship rates are applied to the population projections by sex and age, and in some cases by marital status.

119. The United Nations has prepared provisional projections of households by the headship rate method for the world and 24 regions for the period 1965-1985. These projections are summarized in table XV.12. The future levels of headship rates were estimated by developing regional models based on data from countries within the region or from countries outside the region having a similar demographic situation, and by multiple regression analyses between sex-age-specific headship rates and economic and social factors—mainly, the pro-

<sup>148</sup> The most recent manual is United Nations/UNESCO, *Estimating Future School Enrolment in Developing Countries* ... (1966). This manual contains detailed methodological case studies estimating future school enrolment for Colombia, 1961-1981, for the Philippines, 1965-1980, and for the Sudan, 1962-1971, as well as examples of projections made in various more developed countries. Earlier publications on methodology include: Jacoby, *Methods of School Enrolment Projection* (1959); Goldstein and Swerdloff, *Methods of Long-Term Projections of Requirements for and Supply of Qualified Manpower* (1967); UNESCO, International Institute for Educational Planning, *Manpower Aspects of Educational Planning* ... (1968).

<sup>149</sup> See, for instance, Conger, "College and university enrolment projections" (1962).

<sup>150</sup> Tilak, "Some problems in projecting the economically active population" (1967).

<sup>151</sup> United Nations, *Manual VII: Manual on Methods of Projecting Households and Families* (1973).

<sup>152</sup> United States, National Resources Committee, *The Problems of a Changing Population* ... (1938).

<sup>153</sup> The following are examples of projections based on the "headship rate" method. United States of America, Bureau of the Census, *Illustrative Projections of the Number of Households* ... (1958); Pressat, "Un essai de perspectives de ménages" (1959); Cullingworth, *Housing Needs and Planning Policy* (1960); the Netherlands, Central Directorate of Housing and Building, *Monograph on the Housing Situation in the Netherlands* (1964); Tamásy, "Projections of families in Hungary ..." (1967); Japan, Institute of Population Problems, *Zenkoku todofuken-betsu setaisu no shorai suikei* ... (1966).

<sup>154</sup> For examples of projections based on simple mathematical extrapolation, see Dousa, "Problémy zjstovani perspektivni skladby domacnosti" (1959); Sentić and Breznik, "Demografska kretanja i projekcije u Jugoslaviji" (1964).

<sup>155</sup> For a discussion of some of the more complex methods see Brown, "Analysis of a hypothetical stationary population ..." (1957); Glass and Davidson, "Household structure and housing needs" (1951); Illing, *Population, Family, Household and Labour Force Growth to 1980* (1967).

<sup>156</sup> Examples of such projections include: United States of America, National Resources Committee, *The Problems of a Changing Population* ... (1938), p. 25; Calot, "Perspectives du nombre des ménages ..." (1964); Walkden, "The estimation of future numbers of private households ..." (1961); Belgium, Institut National du Logement, *Estimation des besoins en logements* ... (1965).

<sup>157</sup> The following projections have assumed changing headship rates: United States of America, Bureau of the Census, *Illustrative Projections of the Number of Households* ... (1958); Cullingworth, *Housing Needs and Planning Policy* (1960); Japan, Institute of Population Problems, *Zenkoku todofuken-betsu setaisu no shorai suikei* ... (1966); Schubnell, "Statistical ascertainment of households and families in the census ..." (1969); Calot et al., *Projections démographiques pour la France* ... (1970).

TABLE XV.12. PROJECTIONS OF THE NUMBER OF HOUSEHOLDS FOR MAJOR AREAS AND REGIONS OF THE WORLD, 1965-1985

SOURCE: *Demographic Aspects of Households and Families* (to be issued as a United Nations publication).

portion of the male labour force engaged in non-agricultural activities, *per capita* income, labour force participation rates and marital status composition. In general, the projected headship rates are shown to increase moderately over time.

120. According to the medium variant projections, as shown in table XV.12, the number of households in the world as a whole, estimated at 725 million in 1965, will increase to 1,174 million by 1985, an increase of 62 per cent. This is faster than the rate of increase of the population, since a declining trend in average size of household is projected. Thus, whereas the average household is estimated to have had 4.54 persons in 1965, this figure is expected to gradually decrease, and to reach 4.20 by 1985.

121. Average household size is shown to decrease in the future in most of the major regions as a result of the expected world-wide fertility decline. However, the projections show an increase in average household size in some regions of Africa, as well as in South Asia up to

1975. In Africa this increase results from the fact that fertility is not expected to decline in most regions until after in the century. Moreover, the anticipated continuous declines in mortality in all regions can offset the effects of fertility decline when the latter is not of great magnitude.

122. The table also shows that there is likely to be a trend towards a convergence of average household size in the different regions. By 1985 the range of projected averages is narrower than it was initially in 1965. This is mainly a reflection of the trend towards convergence with respect to fertility, mortality and nuclearization of the family (see chapter X).

123. Despite the larger average household size in the developing regions, which means that the number of households relative to the population is lower than in the developed regions, the sheer magnitude of the growing numbers of households in the developing regions is impressive. The absolute number of households is expected to grow much faster in the developing than in the developed regions, and consequently the share of the world's

households in the former regions will increase—from an estimated 60 per cent in 1965 to about 65 per cent in 1985. The expansion in the number of households is expected to amount to 15 to 16 per cent during each five-year period from 1970 to 1985. It is easy to foresee how prevailing housing shortages may be further aggravated by such growth.

124. In addition to projections of the total number of households, demands have been growing for more detailed types of projections by household composition. These include projections of households of different sizes, that is, projections of one-person, two-person households etc. Such projections are useful for planning in such areas as housing, social development, the production and distribution of consumer durable goods, and the like. Such planning is likely to become even more important in the future. Few such projections have been prepared thus far, however, owing to the paucity of pertinent data and the inadequacies of existing methodology.<sup>158</sup> Projections of this kind thus remain essentially at an experimental stage and await the development of more elaborate techniques.

#### 6. THE NEED FOR A CO-ORDINATED SYSTEM OF DEMOGRAPHIC PROJECTIONS

125. The broad view of the field of demographic projections considered in this section points out the mutual interrelations that exist between the dynamic factors producing changes in the over-all size and sex-age composition of a country's population and the changes occurring within specific socio-economic sectors of that population.

126. As has been observed, the principal influence by far in changes in the size of the labour force is exerted by changes in the size and sex-age composition of the total population. Changes in the size of the population of school-age is, of course, an important factor in the changes in school enrolment, although many factors of a legal, economic or political policy nature intervene to determine the actual size of the student population at various levels of education. Conversely, the differential patterns and trends in fertility and mortality as between the rural and urban components of a country's population are a determinant of the changes that occur in the size and sex-age composition of a country's total population. There are also interdependencies of varying degrees between some of the above-discussed socio-economic categories of population. For example, changes in school enrolment for grades above a certain level, or changes in the average number of years of school completed by school-age youths can produce certain corresponding changes in

their labour force participation rates and therefore in the size of the labour force. Likewise, changes in marriage rates or in the average age of marriage exert an influence either on labour force participation rates or school attendance rates, in addition to the effect on family or household formation and ultimately on changes in fertility rates. There are also certain reciprocal relationships between the agricultural population, the rural population and the economically active population.

127. These and other interrelationships among the sectoral components or socio-economic categories of the population point up the need for a co-ordinated system of demographic projections that are reconcilable with a common set of total population projections by sex and age.<sup>159</sup> In addition, there is, of course, the necessity of maintaining consistency among projections of the labour force, school enrolment and families or households which are based on total population projections by sex and age in combination with appropriate participation and headship rates specific for sex and age. Projections of the population dependent on agriculture should be internally consistent with corresponding projections of the agricultural labour force on the one hand, and with the rural population on the other.

128. The usefulness of a co-ordinated system of demographic projections which reflects the effects of the strictly demographic variables on population size and sex-age composition and the effects of economic and social factors on occupational structure, urban-rural distribution, educational level etc. is illustrated in a recent study by Macura. Utilizing available projections of population in functional age groups and of population structures, in terms of broad economic sectors and urban-rural distribution, the author examined the multidimensional interactions of alternative levels of economic development and population growth projected to the end of this century. The analysis illustrated the difficulties of achieving rapid economic development and bringing about significant changes in population structure under conditions of rapid population growth. At the same time it also suggested the need for rapid economic growth in order to bring about population change.<sup>160</sup>

129. Work on total population projections by age and sex is much more advanced methodologically than the other types of demographic projections, although further progress is desirable, particularly in modifying and updating model life tables, developing the cohort approach in projecting fertility, and studying the factors influencing future trends of international migration. Improved projections of urban and rural population, based on the component technique, call for the development of better measures of rural-urban differentials in fertility and in mortality, better measures (both direct and indirect) of internal migration and of the short and long range effects of migration selectivity on patterns of fertility and mortality.

<sup>158</sup> For examples of such projections, see Brown, "Analysis of a hypothetical stationary population ..." (1957); Glass and Davidson, "Household structure and housing needs" (1951); Tamásy, "Projections of families in Hungary ..." (1967); Schubnell, "Statistical ascertainment of households and families in the census ..." (1969). The United States of America, Bureau of the Census has prepared projections of the number of households by various family types, such as husband-wife type households, single-member households and others. See United States of America, Bureau of the Census, *Projections of the Number of Households ...* (1968).

<sup>159</sup> As indicated in other chapters, the interrelationships on which a co-ordinated system of projections is based have not yet been sufficiently studied, so that the projections themselves cannot be expected to be completely satisfactory at the present stage.

<sup>160</sup> Macura, "Demographic prospects for the next thirty years" (1971).

130. In terms of model development, more research needs to be focused on the influence of various levels of educational attainment on fertility and mortality differentials within the urban and rural environments, respectively. The results of such research used in conjunction with projected levels of educational attainment would help improve the efficiency of the model used for population projections. The suggested research would also help to determine to what extent rural-urban differences in fertility and mortality are due primarily to educational differentials rather than to "urbanism" or "rurality" *per se*.

#### D. The use of demographic projections in planning

131. In the shaping of national development strategy—at the policy-making levels and in planning—it is increasingly recognized that many demographic variables have to be considered in conjunction with economic and social variables. While these demographic variables are influenced by prevailing economic and social conditions, the latter are in turn influenced by population growth and structure. Because of their complexity, these interrelationships between demographic, economic and social factors are not easy to study and are not yet well understood. For planning purposes, the need for studying the relation of population size, density, growth and structure to available resources, levels of development and economic growth have been particularly stressed. In addition, it is important to have information concerning the size and growth of population components such as the child population, the school-age population, the working-age and old-age population and other population segments which are directly related to the functioning of the national economy, or which require specific social services.<sup>161</sup>

132. Improved knowledge of the interrelationships of various demographic and other factors is essential in order to provide a firm basis for different types of demographic projections. These projections are needed at every step of national and regional planning, since the population of a country is both the producer and consumer of goods and services. Hence, population trends play a major role in determining the size and composition of the labour supply, as well as the volume and composition of consumption needs.<sup>162</sup>

133. Although the importance of demographic projections for development planning is widely recognized, current planning techniques do not adequately allow for demographic considerations as integral components of economic and social development. Macura has noted that the existing economic models usually comprise population and labour force variables, either explicitly or implicitly, but with a rather limited scope.<sup>163</sup> On the other hand, demographic models and projections are often limited to population variables in the narrow sense—generally

fertility, mortality, and the size and sex-age structure of the population.<sup>164</sup> These limitations can be expected to be gradually overcome with the improvement of data and basic knowledge needed for the development of comprehensive models.

134. In view of the interdependence between demographic variables and economic and social development, the results of population projections based on purely demographic analyses sometimes have to be modified to take account of the probable effects of the development plan.<sup>165</sup> The preparation of such modified projections requires close co-operation between demographers, planners and the varied institutions engaged in development planning.<sup>166</sup>

135. Demographic projections of various kinds have applications in planning both at the national and regional levels. Estimates of future total population are essential at the first step of planning when general targets of development are set out.<sup>167</sup> One of the principal targets of an economic development plan is an increase in income, which is not independent of the rate of population growth. If the plan assumes an increase in the aggregate income, the corresponding change in *per capita* income—and consequently of the level of living—will obviously depend on the growth of population. If the target is to increase *per capita* income, one needs to know the future size of the population in order to estimate the aggregate quantity of national income that has to be produced.<sup>168</sup>

136. The principal kinds of demographic projections which have been developed in recent years have been discussed in earlier sections of this chapter. They include projections of the population by sex and age, projections of labour force, urban and rural population, agricultural and non-agricultural population, school enrolment, and households and families. The roles and uses of different kinds of demographic projections in each of the principal sectors of planning are discussed below.

#### 1. INDUSTRIAL DEVELOPMENT

137. Manpower projections are of particular importance in the process of development planning, since they measure the future employment needs of the population, and full employment is often considered among the primary development targets.<sup>169</sup> Along with measures of

<sup>168</sup> On the role of the rate of population growth in target setting, see, for example, United Nations, Economic Commission for Asia and the Far East, *Programming Techniques ...* (1960), pp. 12-13.

<sup>169</sup> United Nations, Economic Commission for Asia and the Far East, "Economic development and planning in Asia and the Far East" (1955), p. 34. In the less developed countries, because of the large backlogs of unemployment and under-employment which frequently exist, planning goals often cannot aim at full employment, but may have more modest goals of providing employment  
(Continued on next page)

economic factors, labour force projections provide the basis for estimating future economic growth in general and in manufacturing and related industries in particular. Classified by such characteristics as sex, age, educational level, occupation and industrial sector, they may be matched against projections of labour demand in order to assess probable surpluses or shortages of different types of labour. Such analyses permit corrective measures to be taken, for example, through adjustments in employment plans, or in educational and training programmes.<sup>170</sup> Information on the availability of various kinds of skilled labour, which can be estimated from educational and training programmes, is usually of special importance for development planning.<sup>171</sup>

## 2. AGRICULTURAL DEVELOPMENT

138. Projections of the size and sex-age composition of the total population are used in calculating prospective food demands, based on the nutritional requirements of different population groups. Food production goals set on the basis of such projections have implications for various other aspects of planning, such as investment in agriculture and related sectors, the training of workers and the application of new techniques. Closely related are estimates and projections of the agricultural labour force and its demographic characteristics. These are needed for formulating measures to raise agricultural productivity and for shifting surplus workers to the non-agricultural sector. In addition, projections of total agricultural population, including both workers and dependants whose main sources of livelihood is in the agricultural sector, are needed for estimating the adequacy of income in this sector and assessing the extent of agricultural overpopulation. Projections of agricultural population also permit the calculation of the marketable surplus of agricultural production.<sup>172</sup>

## 3. EDUCATION

139. School enrolment projections for the different educational levels, derived by applying forecasts of enrolment ratios to the population projections of school-age population, provide the basis for developing adequate teacher training programmes, as well as plans for school

and college construction.<sup>173</sup> These projections are also indispensable for estimating the cost of the educational system; the higher the ratio of the projected school-age population to the total population, the greater the need—other things being equal—for teachers, classrooms, books etc.<sup>174</sup> Planning in the education sector involves not only providing basic facilities to meet the demands of the cohorts of school-age population, but also calls for improvements in quality and changes in types of education to equip the future labour force with the skills required by an industrializing economy.<sup>175</sup> Long-term projections of manpower requirements are thus desirable for educational planning, while shorter-term forecasts of manpower needs are basic to vocational training programmes.<sup>176</sup>

## 4. HEALTH

140. Population projections provide the means for more accurately anticipating demands for various types of medical facilities, such as hospital beds and health care units, and for specialized medical and health personnel.<sup>177</sup> As medical needs vary markedly with age, and to some extent with sex, the sex and age composition of the future population is particularly pertinent.<sup>178</sup> Different health programmes have to be developed for young children—the group hardest hit by disease—for workers in particular occupations and industries,<sup>179</sup> and for aged persons, who constitute an increasing proportion of the population in many countries.<sup>180</sup>

141. The planning of other programmes closely related to health conditions, such as sanitation services, including

<sup>172</sup> For a discussion of the role played by demographic factors in planning for food and agricultural development, see United Nations, *Report of the Interregional Seminar* ... (1969), pp. 20-23; —, *Current Status and Development of Demographic Studies* ... (1969), pp. 19-24. See also Food and Agriculture Organization of the United Nations, "Methods and assumptions for projections of agricultural population" (1969).

<sup>173</sup> See, for example, United Nations, *General Principles for National Programmes* ... (1965), p. 22; United Nations/UNESCO, *Estimating Future School Enrolment* ... (1966), pp. 10-11; United Nations, *Science and Technology for Development* (1963), vol. 6, p. 41.

<sup>174</sup> Sauvy has noted that "Fortunately, the increasingly widespread practice of making population forecasts makes it possible to calculate several years ahead, on the national scale, the number of pupils covered by compulsory education and the number of teachers in certain hypothetical cases. Although local contingencies consequent on internal migration remain, school building plans can be drawn up with some assurance, and an unexpected increase in the number of pupils can no longer qualify as an excuse." water supply and sewerage, has to rely on data obtainable from population projections for small areas.<sup>181</sup>

## 5. HOUSING

142. The rate of population growth in urban and rural areas, and more particularly, changes in the number and size of households or families, are essential data for estimating future housing needs.<sup>182</sup> Household or family projections give an indication of the number of new dwelling units which must be provided during a given time to house the population according to any given standard of accommodation; additional units may be required to make up for existing shortages and to replace dilapidated dwellings.<sup>183</sup> Projections of changes in household or family composition by sex, age and marital status provide important information for calculating needs for housing units by type and size.<sup>184</sup> Besides estimates of

graphic indicators helping to determine ..." (1967), pp. 431-437; Steigenga, "The contribution of demography ..." (1969), pp. 124-126.

## 6. REGIONAL AND URBAN DEVELOPMENT

143. Since rates of population growth and the composition of the population are not identical in different regions of a country, planning for the development of different areas requires separate demographic projections for subnational areas.<sup>185</sup> Projections for urban and rural areas, which take into account differences in natural increase and the rate of rural-to-urban migration, are particularly valuable owing to the substantial differences in economic and social conditions between such areas. Local projections for small areas may also be required for such purposes as the planning of housing projects, school construction, the location of industrial plants, provision of adequate hygienic and sanitary installations, transportation, and the like.<sup>187</sup>

## Chapter XVI

### DEMOGRAPHIC CONSIDERATIONS IN PLANNING

1. In general terms, planning may be described as the rational process whereby the best manner for achieving certain goals with the available means is identified and defined. Economic and social planning may thus be said to involve the translation of the general objectives of economic and social policy into a set of consistent, quantified targets and the selection and determination of the measures and means necessary to achieve those goals. Planning, while not providing by itself a solution to problems, determines through a systematic analysis how the general policy objectives, adopted following an examination of alternative policies, can be fulfilled, taking into account the limited amount of resources and other constraints which the policy-makers have to face.

2. This chapter broadly examines the role of demographic factors in planning for economic and social development. The sections of the chapters are concerned with demographic considerations in economic planning, in planning for selected social sectors—education, health, housing—and in regional planning; and with family planning in so far as such policies are an integral part of planning and plans.<sup>1</sup> Although some general comments on planning are included, the chapter is not concerned with the methodology and organization of planning, the implementation and evaluation of plans or with the techniques for projecting demographic variables needed for planning.<sup>2</sup> It is only incidentally concerned with strictly economic considerations in planning and, therefore, does not discuss extensively those aspects which figure prominently in the economic literature on the subject. Finally, no systematic coverage of existing economic and social plans has been attempted; only selected and a limited number of plans have been discussed to illustrate the variety of approaches in dealing with demographic factors in economic and social planning. In discussing these aspects a distinction is made, as is customary in much of the literature, between the centrally planned economies, the developed market economies and the developing market economies, even though such a classification rests more on practical considerations than on appropriate scientific criteria.

3. A wide diversity exists with regard to the approaches, the scope and the importance assigned to planning. Planning on a systematic scale is a relatively recent phenomenon. It was initiated in the USSR shortly after the revolution of 1917 when the transition to and the

establishment of the socialist system, with its collective ownership of the predominant part of the productive capacity of the economy, made comprehensive planning imperative.<sup>3</sup> In the Eastern European countries, planning is more recent and has its beginnings in most cases with the establishment of the socialist system after the Second World War.<sup>4</sup> In this period, planning also became increasingly important in the developed private enterprise or market economies, especially those of western and northern Europe.<sup>5</sup> The rapidly growing importance of planning in recent times, however, has been mainly attributed to the need felt by the economically less developed countries, many of which gained independence in this period, to promote their economic growth and social advancement.<sup>6</sup> Planning has thus emerged as a tool of policy in countries differing widely not only in their economic and social systems, but also in their stages of development.

#### A. Approaches to planning and the role of population

4. The approaches to and methods of planning differ substantially, as Myrdal and others have noted, according to the prevailing level of development and the institutional framework.<sup>7</sup> A number of writers have discussed the specific differences in this respect. In the economically less advanced, as opposed to the more developed countries, the major issues in planning, it is asserted, revolve

<sup>3</sup> For the origins and development of planning in the USSR, see among others, Strumilin, *Ocherki sotsialisticheskoy ...* (1959) and his *Planning in the Soviet Union* (1957), pp. 14-25; Sorokin, *Planirovanie narodnogo khoziaistva SSSR ...* (1961); Cherkovets, *Planomernost sotsialisticheskogo proizvodstva* (1965); Bor, "The organization and practice ..." (1965); Kursky, "Development of forms ..." (1966); Dobb, *Soviet Economic Development ...* (1966), chaps. 4-13.

<sup>4</sup> For the development of planning in some Eastern European countries, see Rakowski, *Zagadnienia planowania ...* (1955); Marczewski, *Planification et croissance économique des démocraties populaires*, tome 1 ... (1956); Brus, *Ogólne problemy ...* (1961); Vergner, "Economic planning ..." (1965); Jelic and Orthaber, "Some characteristic features ..." (1965); Wellisz, *The Economies of the Soviet Bloc ...* (1966); Seth, *Theory and Practice ...* (1967), pp. 234-294.

<sup>5</sup> For a discussion of the background to planning in these countries, see Myrdal, *Beyond the Welfare State ...* (1960); Wellisz, "Economic planning ..." (1960); Shonfield, *Modern Capitalism* (1965); Bjerve, *Planning in Norway ...* (1959).

<sup>6</sup> United Nations, *Planning for Economic Development ...* (1963), p. 1; United Nations, Economic Commission for Asia and the Far East, "A decade of development planning ..." (1961).

<sup>7</sup> Myrdal, *Beyond the Welfare State ...* (1960), chap. 8; United Nations, *Planning for Economic Development ...* (1963), pp. 2-3; Jelic, "Some problems ..." (1965); Caire, *La planification ...* (1967), p. 33; Tinbergen, *Lessons from the Past* (1963).

<sup>1</sup> Policies and measures affecting fertility are discussed more generally in chapter XVII.

<sup>2</sup> The techniques of population projections and other aspects related to them are discussed in chapter XV.

around the acceleration of the rate of development, higher levels of income and productivity and the diversification of the economy. The most crucial factor in this connexion is often thought to be the scarcity of resources and in most, though not all, of these countries the stepping up of the rate of capital formation occupies a central place in planning. In the more developed countries, with a high productive capacity, the level of capital formation, according to these writers, does not constitute a special problem. A high rate of economic growth, while also a basic goal in planning, is often subject to the fulfilment of other conditions—such as full employment, a balance-of-payment equilibrium, a certain measure of price stability and, in some cases, the reduction of income inequalities among social groups or geographical areas.<sup>8</sup> Differences in the institutional framework, such as the different forms and extent of ownership and control over the means of production in the centrally planned economies as compared with the market economies, have also been stressed in explaining basic differences in planning. In the former, it has been noted, planning is comprehensive and centralized, with most targets being translated into guiding principles, which become binding for the different sectors, branches and industries. In the market economies, however, plans are mainly intended to provide coherent targets for production and investment, but, except for the public sectors, the decisions of the individual enterprises can only be indirectly influenced.<sup>9</sup>

5. Despite these differences in approaches and methods, the planning process as such has certain common traits. Actual planning techniques are based as a rule on models which contain the elements entering into planning.<sup>10</sup> Among the elements of planning, a basic distinction is that between the targets of the plan—that is, the objectives stated in quantitative terms—and the means or instruments, both quantitative and qualitative, needed and available for attaining the targets. Other elements that writers have distinguished, apart from targets and means, are the data, constraints or exogenous variables

<sup>8</sup> Mahalanobis, "Some observations ..." (1953); United Nations, *Planning for Economic Development* ... (1963), p. 3; United Nations, Economic Commission for Latin America, *Analyses and Projections of Economic Development*, I ... (1955), p. 1; United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1962*, part II ... (1965), chap. 1, p. 5.

<sup>9</sup> United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1962*, part II ... (1965), chap. 1, p. 3; Sevaldson and Trzeciakowski, "Construction and application ..." (1967); Strumilin, *Planning in the Soviet Union* (1957), pp. 4, 12. Planning in the centrally planned economies is sometimes referred to as "direct" or "imperative" planning, whereas in market economies it is supposed to be "indirect" or "indicative". See United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1962*, part II ... (1965), chap. 1, p. 3; Bénard, "Problèmes et instruments ..." (1958); Fourastié et Courthéoux, *La planification économique en France* (1968), pp. 112-116; Black, "The theory of indicative planning" (1968). Recent literature, however, suggests a trend towards a narrowing of these differences between planning in the socialist and the market economies. See, for instance, Sevaldson and Trzeciakowski, "Construction and application ..." (1967).

<sup>10</sup> United Nations, "Use of models ..." (1961), defines models as "an organized set of relationships that describes the functioning of an economic entity, whether it be a household, a single industry, or a national economy, under a set of simplifying assumptions". Many other definitions have, however, been suggested and used.

which must be considered as given by the planning authorities and which reflect certain technical, behavioural and institutional parameters. They may include natural resources and climate, technical processes, international factors and certain other characteristics. Finally, there are the structural relationships; these describe the behaviour and structure of society and specify the interdependence between the variables and factors involved in the planning process and the limitations and constraints which the policy-maker must take into account.<sup>11</sup> It has also been noted, however, that although conceptually the distinction between these different factors and elements of a plan is clear, the dividing line between them may shift with the premises and actual conditions of planning.<sup>12</sup>

6. Planning involves a wide range of issues and activities and, consequently, plans or programmes may exhibit large differences in scope and content. Although no simple classification of planning and plans exists, differences in types and forms of planning are generally acknowledged. In this manner a distinction is sometimes made between economic planning and planning for social development. In recent years, regional planning has emerged as an important category. However, a classification of plans along these lines is, according to many writers, only partially valid. Different types of plans can be considered independent of each other only to a limited extent. Thus, the interdependence of economic and social development and planning has been increasingly recognized and stressed.<sup>13</sup> Likewise, regional planning is no longer viewed as an isolated activity, but has come to be considered and dealt with as an integral part of planning at the national level.<sup>14</sup>

7. Another distinction often made is that between general plans or programmes, sectoral plans, and pro-

<sup>11</sup> Tinbergen, *On the Theory of Economic Policy* (1952), pp. 3-5; Chenery, "Development policies ..." (1958); Strumilin, *Planning in the Soviet Union* (1957), pp. 12-13; Bjerve, *Planning in Norway* ... (1959), chap. 2; United Nations, "Use of models ..." (1961); Horvat, "Methodological problems ..." (1962); Boudeville, *Les programmes économiques* (1965), pp. 20, 25-26; Tinbergen, *Economic Policy* ... (1967), pp. 4-5; Sevaldson and Trzeciakowski, "Construction and application ..." (1967).

<sup>12</sup> Weststrate, *Economic Policy* ... (1959), p. 7, noted, for instance, that in most plans it is possible to discern two orders of objectives: the ultimate aims and the subsidiary goals, which often have a certain instrumental value. On the different roles—as targets, instrument, and exogenous variables—of different factors, including institutional characteristics, under different conditions, see Chenery, "Development policies and programmes" (1958); United Nations, Economic Commission for Asia and the Far East, "A decade of development planning ..." (1961); United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1962*, part II ... (1965), chap. 2, p. 1, chap. 4, p. 1; United Nations, Economic Commission for Europe, *Macro-economic Models* ... (1967), pp. 13-14.

<sup>14</sup> United Nations, Economic Commission for Europe, "Problems of regional economic planning ..." (1965).

jects. Usually, it is asserted, the first step in planning is the determination of the general rate of development which a country seeks to attain, and general programming provides a framework for the possible development of the economy in terms of the most important aggregate variables, such as national output or income; consumption, savings and investments; imports and exports.<sup>15</sup> The concept of sector used in planning varies widely and includes both planning for the economic and for the so-called social sectors. Planning for economic sectors has been said to involve the determination of the planned level and composition of output and the productive resources required to achieve these targets. In its simplest form, such sectoral planning is based on a differentiation among only a few strategic sectors, ignoring the interrelations between sectors. The more complex sectoral plans distinguish a large number of sectors and stress the interrelations and complementarities between industries, branches or sectors, frequently through the use of input-output analysis or inter-industry relations.<sup>16</sup> Projects, finally, refer to the smallest units considered in programming, such as the establishment of a single industry or factory, the construction of a road or bridge, or the production of determined goods and services.<sup>17</sup> Despite these differences in the various types of plans and programmes, many authors have stressed their interdependence. Different types of plans, it is asserted, are linked in a number of ways by virtue of the interrelations which exist between the over-all growth or development of the economy and that of its constituent parts. Comprehensive planning, which encompasses all the factors which play a role in economic growth and social advance and extends to all facets of these processes, including regional planning, will therefore be necessary, it is held, in order to ensure the consistency of the various plans with each other and with total resources.<sup>18</sup>

<sup>16</sup> United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic Development* ... (1960), p. 19; United Nations, *Planning for Economic Development* ... (1963), p. 8. The United Nations study, "Use of models ..." (1961), noted that the subdivision of the economy into a large number of sectors is primarily of importance to countries which have already achieved a certain degree of development and hence have a substantial volume of inter-industry transactions.

<sup>17</sup> United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic Development* ... (1960), p. 33; United Nations, Economic Commission for Latin America, *Manual on Economic* ... (1958), pp. 4, 9-12.

<sup>18</sup> Tinbergen, *The Design of Development* (1958), pp. 20-21; United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic Development* ... (1960), p. 19; Chenery, "Development policies ..." (1961); United Nations, *Planning for Economic Development* ... (1963), pp. 8-9, 27-29; Flecha, *Técnica de planificación económica* (1966), pp. 40-42. In connexion with the different types of plans, a distinction is sometimes made: "planning from below", where plans are made first for individual enterprises or goods and then aggregated, or "planning from above", where the formulation of a general programme constitutes the first step in planning. Tinbergen, *Central Planning* (1964), p. 16; United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic*

8. Plans differ not only as regards their contents and scope, but also in the planning period, that is, the time over which the given objectives and targets are supposed to be reached. As far as the plan duration is concerned, a threefold classification has developed: long-term or perspective plans, medium-term plans, and short-term plans. Long-term plans may cover a period of from one to three decades; medium-term plans have a duration varying between three and seven years and short-term plans are mostly formulated for a period of from one to three years.<sup>19</sup> Ideally, it has been argued, planning must be conceived of as an integrated system of long-term, medium-term and short-term plans.<sup>20</sup>

9. The role of demographic factors in planning derives from their nature as both determinants and consequences of economic and social progress. The population and its functional subgroups as both consumers and producers play a basic role in determining economic and social development. The size, growth, composition and the distribution of the population are considered basic in determining consumption aims and, especially through the working-age contingent, production and employment goals. The same factors are also involved in all those sectoral plans which concern certain segments of the population, such as children, youth, working adults, the retired and the elderly, urban and rural population and so forth. The demographic variables relevant to planning thus include: population size and growth as well as its components; sex-age structure; spatial distribution of the population, internal migration and urbanization; and international migration. In addition, demographic factors may be considered as consequences of planning since they can be expected to undergo change as a result of the planned development process. Mortality, fertility, population growth, composition and distribution all may be affected by the planned development, either directly or indirectly. Specifically, if a population policy is part of development planning and implementation, a changed rate of population growth or a different regional distribution may be seen as one of the targets of the plan. Even in the absence of an explicit population policy, the economic and social changes resulting from planning are likely to have their effect on virtually all demographic factors mentioned.

10. The necessity to consider the nature of demographic variables in planning as both determinants and conse-

*Development* ... (1960), p. 87; United Nations, Economic Commission for Latin America, *Analyses and Projections of Economic Development*, I ... (1955), p. 18.

<sup>20</sup> United Nations, *Planning for Economic Development* ... (1963), p. 7; Seth, *Theory and Practice* ... (1967), pp. 98-99. A relatively recent practice which can ensure the continuity of plans of different duration is that of introducing "rolling plans", which are medium-term plans with another year being added as each year is completed.

quences has been widely recognized.<sup>21</sup> Nevertheless, in practice, the incorporation of demographic variables in the plans of most countries is less than complete, owing to a number of reasons. Planning, it has been noted, cannot take adequately into account demographic variables in the absence of reasonably accurate demographic data and the determination of their role in models for programming.<sup>22</sup> Another obstacle is the as yet limited understanding of the interrelationships between demographic, economic and social variables. While such knowledge has been improving, further advances would enable the planner to take into account both the implications of prospective population trends for economic and social conditions and the effects of the latter upon demographic variables.<sup>23</sup> As has also been noted before, the current planning techniques and demographic models do not permit the integral treatment of demographic variables in planning. On the one hand, the existing economic models and planning procedures do not make allowance for a more detailed consideration of demographic factors; on the other, the demographic models seem to be limited to population variables in a narrow sense.<sup>24</sup> In many countries, however, planning is only a recent phenomenon and the lack of integration of demographic variables in their plans is the result of the limited experience in planning rather than of the failure to recognize the importance of population factors for planning.

## B. Demographic considerations in economic planning

11. As noted, the first step in comprehensive economic planning is usually the formulation of the general programme, or plan. Based mainly on mathematical models of the economy formulated in terms of the main aggregate variables, the general programme is said to provide the framework for translating the major objectives of planning into basic targets and makes it possible to assess the feasibility of these goals in terms of the available resources and existing constraints.<sup>25</sup> The objectives of the general programmes are based primarily on political considera-

tions, value systems and so forth. Although it has been recognized that such objectives, therefore, may vary according to national circumstances, many writers have stressed common elements. Plans of this type, they assert, are generally concerned with determining the possible or desired rates of growth of income, product or consumption, the division of the national product among consumption, investment and exports, as well as the expected or required volume of domestic savings, imports and foreign financial assistance.<sup>26</sup> Basically, two approaches to formulating a general programme have been distinguished. The first, which has been referred to as "explanatory" by Perroux, is based on a study of past trends, including a diagnosis of the national economy, and an analysis of the feasible and probable future changes. An over-all survey of this nature provides the planning authorities with an assessment of the growth potentialities of the economy and the efforts required to attain given rates of development. In the second approach, described as "normative", first the targets of economic development in terms of national income, production, or other variables are set and subsequently the conditions for attaining such objectives are examined.<sup>27</sup>

12. It has also been recognized, however, that general programming in setting the over-all rate of development provides a less than complete picture of that process. Development implies, in addition, changes in the composition of the demand for goods and services, the supply of factors of production and their productivity, the structure and the degree of diversification of the economy, and so forth. It is for this reason that planning by sectors is considered a necessary complement of general programming.<sup>28</sup> It is argued that, whereas general programming—by determining the main economic variables—provides a test of consistency of sectoral and partial plans,<sup>29</sup> the latter in turn make it possible to detect obstacles to growth and to determine the conditions for a "balanced" or "proportionate" expansion of all sectors.<sup>30</sup>

<sup>23</sup> United Nations, *Seminar on Evaluation and Utilization of Population Census Data in Asia and the Far East* ... (1961), p. 5.

<sup>24</sup> See chapter XV, sections C and D.

<sup>25</sup> Tinbergen, *The Design of Development* (1958), pp. 9-10; Mahalanobis, "Some observations ..." (1953); United Nations, Economic Commission for Latin America, *Analyses and Projections of Economic Development*, I ... (1955), p. 3; United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic Development* ... (1960), p. 8; United Nations, "Use of models ..." (1961). Models involving the main macro-economic variables are usually referred to as aggregate models. A typical aggregate model might include (a) technical equations, principally the production function which determines output or product as a function of one or more inputs; (b) behaviour and institutional equations, such as consumption or saving functions, import and export functions etc.; and (c) balances, equations or "constraints" which specify the necessary relations between different variables, such as the equality of total resources and total expenditures.

<sup>26</sup> Tinbergen, *The Design of Development* (1958), p. 19; United Nations, "Use of models ..." (1961); United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic Development* ... (1960), p. 8.

<sup>27</sup> For a discussion of the first approach, see United Nations, Economic Commission for Latin America, *Analyses and Projections of Economic Development*, I ... (1955), p. 3. For the second approach, see United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic Development* ... (1960), p. 81. See also United Nations, Economic Commission for Asia and the Far East, "A decade of development planning ..." (1961); Caire, *La planification* ... (1967), pp. 238-295. Perroux, *Les techniques quantitatives* ... (1965), pp. 33-34, commented that, theoretically, planning requires models of both the first (explanatory models) and second types (normative models).

13. Demographic considerations are involved in the planning process in a number of ways. Most obvious is the effect population growth and size have in setting the general rate of development, but major implications derive also from the nature of population as both consumers and producers in planning decisions. With the recognition of the importance of demographic factors in this context and with the progress in the techniques of planning, recent literature has to an increasing extent emphasized the importance not only of the size and growth, but also of the structure and composition of population.<sup>31</sup> Therefore, plans of production, consumption, investment, distribution and so forth should, it has been asserted, be closely connected with population factors.<sup>32</sup>

14. Even though general programmes can have a number of objectives, the increasing of the levels of living of the population occupies a central place in most plans. Whether formulated in terms of income or other indicators of levels and conditions of living, such as consumption or employment, these objectives must take into account the size of the population as a basic factor. It has been noted that increases of income—the most common objective in planning—and population growth are linked as fundamental determinants of levels of living and that, mathematically speaking, trends in population can play as large a role in determining *per capita* income as trends in production.<sup>33</sup> Given the targets of economic growth in terms of *per capita* income, population growth will determine at what rate total income or product should increase to attain such targets.<sup>34</sup> Even where targets are set in terms of growth of total income, the population factor, it has been pointed out, determines whether such growth is sufficient to absorb the effects of an expanding population on levels of income.<sup>35</sup> It is because of this linkage between growth of income and growth of population that the regulation of population growth is considered an important means for raising income and levels of living in a number of countries where the growth of population is so high as to jeopardize the chances of attaining the desired levels of living within the foreseeable future.

15. Whereas population growth thus sets a lower limit to the general rates of development, the actual rate which can be planned is limited basically by the available productive resources. In many developing countries, it is frequently held, capital is the scarce factor and constitutes the main bottleneck to rapid economic growth.<sup>36</sup> Where

the major constraint to planning is the level of investment, planning will often proceed in function of a so-called "capital-centred" model of the Harrod-Domar type in which the growth of income is considered a function of the rate of net capital formation and the marginal capital-output ratio.<sup>37</sup>

16. Planning in terms of a capital-centred model does not take explicitly into account demographic factors and one of the criticisms against this approach is that such a model ignores the contribution to production of all factors except capital. Nevertheless, it has been shown that even in capital-centred planning, demographic factors cannot be ignored. In the first place, the growth of population determines the lower limit of investment needed to maintain the existing levels of income. The higher the rate of population growth, the larger these so-called demographic investments have to be. In order to assure an increase in income, productive investments must thus increase at a rate substantially in excess of the rate at which population grows. In the second place, the upper limit of investment is determined by the minimum acceptable share of consumption in national income, which will depend at least in part on demographic factors such as population growth and composition.<sup>38</sup> In the literature on planning, little attention has been given to an additional factor in this connexion, that is, the effects of demographic factors on the patterns and structure of investment. Since a growing population requires large outlays for investments which are not directly productive, such as those in housing, schools, transport and communications, urban facilities and so forth, it will tend to raise the capital-output ratio and thus the required rate of capital formation needed to attain the pre-determined goals.<sup>39</sup>

17. Demographic factors are explicitly incorporated into the planning process where employment is a basic goal of economic policy or where because of serious employment problems planning targets are set primarily in terms of employment creation.<sup>40</sup> Since they are the

(1960), p. 6; International Labour Office, *Employment and Economic Growth* (1964), pp. 125-126; United Nations, *World Economic Survey, 1964*, part I ... (1965), p. 64.

main determinants of the number of potential producers, the size and sex-age composition of the population occupy an important place in "employment-centred" planning. In this type of planning the growth of total population and labour force are usually taken as a point of departure and the plans themselves are based on projections of these variables over the planning period. A simple model of this type would estimate total product as a function of the projected working population and assumptions regarding product per worker, where the latter may be based either on what economic growth is desired in terms of *per capita* income,<sup>41</sup> or on what the possible future trend of output per worker is.<sup>42</sup>

18. Despite the basic differences between capital-oriented and employment-oriented planning, in practice plans formulated on the basis of either of these approaches will often take into account the implications for the other factor. Thus "capital-centred" planning will usually involve some consideration of the consequences for employment of the planned development and, likewise, the assessment of the implications of employment targets for investment is as a rule undertaken in "employment-centred" planning. As a result of such analysis, plan objectives are often modified or adapted to make allowance for their effects on employment or capital formation in, respectively, capital-oriented and employment-oriented planning.<sup>43</sup> In view of the possible conflict between maximizing levels of income and levels of employment, the importance of an approach to planning integrating both aspects has been stressed in a number of writings.<sup>44</sup>

19. The role of demographic factors varies in the planning of different sectors. In the case of planning for consumer goods and investment goods sectors, population in its role as consumer is thought to affect both the distribution between the consumer goods sector and the investment goods sector as well as the composition of demand with respect to each of them. In more general terms, the view has been stressed that, apart from changes in tastes, the demand for consumer goods depends basically on population trends and the level and distri-

bution of income.<sup>45</sup> In literature on the subject, it has also been noted that given the growth of total income, the effect on total consumer demand and its composition may be quite different depending on whether the growth of total income takes the form of a higher *per capita* income or the same *per capita* income for an increasing population.<sup>46</sup>

20. Similar considerations hold for planning for the industrial sectors—agriculture, manufacturing, construction etc.—the purpose of which has been described as the determination of the type and rate of development of each sector in accordance with the targets for consumption, investment and external trade within the limits set by the available resources and the existing economic structure.<sup>47</sup> The needs of the population, as determined by its size and composition, are considered important in determining the demand for various goods and services and for setting targets for specific sectors. Nevertheless, in most cases where population is explicitly incorporated into sectoral planning models, total population only is taken into account.<sup>48</sup> The role of demographic factors has been stressed, especially in the case of agriculture and foodstuffs. Together with the level and distribution of income, population growth and composition—the latter to make allowance for different nutritional or different population groups—are important in determining the future needs and demand for food.<sup>49</sup>

21. Demographic factors are also important in plans for industrial sectors which are concerned with employment considerations. Since increases in over-all productivity can be attained either through productivity increases in individual sectors or through the transfer of labour from less to more productive sectors, changes in the structure of the labour force and its diversification become important.<sup>50</sup> The importance of structural changes in the economy, its implications for employment and the role of demographic factors in this process have been stressed particularly in the case of the developing countries, where this process of industrialization is a key to development.

<sup>41</sup> Since the relation between total and working population is known, the level of product per worker can be derived from the desired level of *per capita* income.

## 1. THE CENTRALLY PLANNED ECONOMIES

22. Planning in the modern sense which, as noted above, emerged with the establishment of the Soviet Union as the first Socialist State, occupies a central place in the development of the socialist countries. Given the ultimate goal of the creation of communism, planning under socialism, as the selection and execution of a strategy of development which will lay the material and technical bases for communism, has several distinctive features. Economic planning is thus considered one of the prime tasks of government and implies a centrally directed and comprehensive system of management of the economy and its active projection.<sup>51</sup> To that end the socialization of all sectors and the social ownership of all means of production is thought to be essential.<sup>52</sup> Planning under socialism, as opposed to conditions existing under capitalism, thus would, according to Lenin, replace the anarchy of production of the former by a planned organization of the social process of production in order to guarantee the welfare and full employment of all members of society.<sup>53</sup>

### (a) *Planning and the role of population*

23. Although the common goal of planning in socialist countries is the creation of communism, specific goals and objectives depend on the stage of development which the country has attained. This is in accordance with Marxian theory, which holds that the mode of economic organization, and hence economic policy, corresponds to the stage of development of the society's material powers of production. Despite this and other differences, planning in the centrally planned economies has certain basic premises in common, which also distinguish it from planning in the non-socialist countries. Since the means of production are predominantly publicly owned, planning in the socialist countries has been called "direct"—as opposed to that in the market economies where it is "indirect"—in the sense that the central authority has the disposition over the preponderant share of national resources and available to it the machinery for economic administration and control at all levels.<sup>54</sup> Moreover, in the centrally planned economies the attainment and maintenance of full employment is a basic principle and fundamental premise of planning. Finally, because the demand for and the supply of consumption and production goods are directly planned, production in these economies, unlike that in the private enterprise or mixed economies, cannot be limited by an insufficient effective aggregate demand.<sup>55</sup> Growth of production and develop-

ment, it has been noted, are thus determined by the supply of factors and the level of national income by the full employment of productive capacity.<sup>56</sup>

24. Among the premises of planning in the centrally planned economies an important place is occupied by the "objective economic law of planned proportionate development of the national economy". As one of the economic laws of socialism, it implies the need for proportionality and determinate priority relationships between different elements and aspects of planning such as between production and consumption goods, industrial and agricultural output etc.<sup>57</sup> In the actual planning process, the "balance" method is used to ensure the maintenance of the necessary proportions in the development of the economy and the consistency between plan requirements and resources. These balances, as devices used for the purpose of co-ordinating and reconciling interdependent indicators, play an important role in determining the links and obtaining the consistency between the basic economic factors, comprising aggregate plans as well as all sectors of the economy. The system includes balances of the material components of production, consumption and accumulation; balances of natural resources; fixed assets; productive capacity; balances of production, distribution and final utilization of national income, as well as manpower balances.<sup>58</sup>

25. Such balances are used in the formulation of the development plan which usually takes place in various stages. In view of the complexity of the planning process, which encompasses a large number of aspects, and the need for co-ordination of the whole plan, the central planning organ prepares, as a rule, first a general model or quantitative framework which contains certain over-all figures including tentative output targets; levels of consumption; availability of equipment and raw materials; labour force and employment and so forth. More detailed sectoral analyses are also prepared and, in a final stage, a consistent plan with respect to both aggregate and sectoral indicators is prepared through successive approximations.<sup>59</sup>

26. Demographic considerations play a role in formulating the strategy of development as well as in the preparation of plans in the centrally planned economies. As a general principle it is taken for granted that the rate of growth of national product will surpass sub-

<sup>59</sup> United Nations, *Planning for Economic Development* ... (1963), pp. 32-33.

stantially the rate of population growth.<sup>60</sup> More specifically, population enters into the planning process in its capacity as both consumer and producer. Demographic projections are used to assess the changes likely to occur in the total population and its segments. From these projections and the *per capita* indicators and standards of consumption for the main functional population groups, consumption requirements are derived, which in turn are confronted and reconciled with the capacity of the consumer goods industries.<sup>61</sup> It is in this context that demographic factors are also introduced in the more general problem of the determination of the proper ratio between investment and consumption and the production of producer and consumer goods.<sup>62</sup>

27. Labour resources and labour productivity are considered the main determinants of the rate of economic expansion, and demographic analyses provide the basis for deriving estimates of the population of working age and in the labour force. This is done by means of manpower balances. The system of manpower balances includes balances of labour reserves which show the state and changes of these reserves during the planning period and especially the manpower balances proper, which establish labour requirements, reconcile them with labour resources and determine the distribution of labour in accordance with the given objectives. The balance of labour resources is derived from demographic data and thus indicates the total population of working age, the active population, and the distribution of labour by sectors. From the number of workers in the productive sector and the estimated productivity of this labour the volume of the national product is derived.<sup>63</sup>

#### (b) *Demographic considerations in economic plans*

##### (i) *An over-all view*

28. Major economic and social changes have been condensed in the centrally planned economies within a relatively short period.<sup>64</sup> The strategy of development in the Soviet Union and the other Eastern European socialist countries<sup>65</sup> responded, especially in the early phases of their development, to the then existing conditions of low productivity, low levels of industrialization and high unemployment. Planning, therefore, emphasized

accelerated industrialization and rapid structural change and, since capital was the scarce factor, increases in the rate of investment figured prominently in the early plans of all these countries.<sup>66</sup> Nevertheless, even in the earlier plans and more so in the later ones, the plans contemplated substantial increases in the production of consumer goods<sup>67</sup> which outpaced population growth.

29. Capital accumulation also was essential and decisive in absorbing the available labour force and for ensuring the full employment of the working population. The transfer of the surplus agricultural population to more productive industrial activities, the absorption of the urban unemployed and underemployed and the increase of labour force participation rates, especially that of females, not only eliminated unemployment, but made possible the achievement of high rates of increase in national product, even with relatively small increases in capital per worker. This absorption of labour force reserves during the early long-term plans in the Soviet Union and those of the Eastern European countries was made possible, it is asserted, through the effective methods of economic control introduced as a result of nationalization and land reforms.<sup>68</sup>

30. As far as demographic considerations were concerned, planning during this period stressed the employment aspect. In the Soviet Union visible unemployment was ended in the course of the First Five-Year Plan (1928-1932) through the industrialization and collectivization of agriculture. Although some underemployment still persisted, the same result was achieved in most Eastern European countries in the early 1950s.<sup>69</sup> Thus, whereas during the early plans the rapidly growing demand for industrial labour could be satisfied relatively easily by incorporating the existing labour reserves into the production process, later, however, labour shortages appeared when large-scale collectivization barely added to the non-agricultural labour supply, the supply of new labour began to decline and urban bottle-necks in housing and services also developed while the demand for labour continued to be high.<sup>70</sup>

31. Once full employment had been attained, high rates of economic growth could no longer be sustained

<sup>69</sup> Shortages of manpower in Eastern European countries existed or manifested themselves early in the German Democratic Republic and, especially, in Czechoslovakia, but in 1950 labour shortages also began to make themselves felt in the other countries. United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1957* (1958), chap. 7, pp. 48-50; ———, *Economic Survey of Europe, 1962*, part II ... (1965), chap. 2, p. 15.

<sup>70</sup> Marczewski, *Planification et croissance* ... (1956), vol. 1, pp. 202-204; United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1959* (1960), chap. 3, pp. 3, 6; ———, *Economic Survey of Europe, 1962*, part II ... (1965), chap. 2, p. 15; ———, *Economic Survey of Europe, 1968* (1969), chap. 3; Litvyakov, "Economic and social factors ..." (1967).

through the use of existing labour reserves. Economic growth came to depend to an increasing degree on increased efficiency and the rate of expansion of the supply of labour which, *inter alia*, led to an increased emphasis on such factors as the sex and age composition of the population, its educational levels and the skills and quality of the labour force.<sup>71</sup> The situation which planners in these countries had to face thus changed considerably: there were large gains in industrial strength and development and the manpower reserves had dwindled. In addition, the rate of population growth had decreased notably.<sup>72</sup> As a consequence of the smaller birth-rate during the war, the comparatively smaller population in the late 1950s and early 1960s became a limiting factor in the growth of employment and production. In most countries, annual increases in the size of the working-age population became smaller and remained below those of the total population, thus resulting in a higher dependency burden.<sup>73</sup>

32. With few exceptions—Albania, Bulgaria, Romania and Poland (the latter because of an expected high increase of young adults between 1960 and 1965)—the centrally planned economies, in formulating their plans for the first half of the decade, had to face the possibility of relative labour shortages. In the course of the Seven-Year Plan (1959-1965) of the German Democratic Republic, the working population was expected to decline by 4 per cent due to the effect of war losses, low post-war birth-rates and mass emigration. Increases in activity rates and further declines in agricultural employment became predominant factors in the expansion of the working force in Czechoslovakia and Hungary. In the former, about half of the expected increment in the labour force was to be recruited among women and the desired growth of the industrial labour force would depend on a decline of agricultural employment by 20 per cent. In the latter country, it was estimated that more than two thirds of the planned increase in the working population would come from the increased employment of marginal labour and an additional increase in the industrial working population would be obtained through a 15 per cent decrease in agricultural employment. In the Soviet Union, the already high share of women in the total working population, the relative decline in the number of students completing their education owing to the expansion of compulsory ten-year schooling, and the slow rate of increase of the working population were some of the factors responsible for an estimated decline of 6 to 7 per cent in the working force between 1958 and 1965.<sup>74</sup>

<sup>74</sup> United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1959* (1960), chap. 3, pp. 3, 7-11.

33. The plans for the period 1966 to 1970 also suggested in many cases smaller relative increases in the industrial labour force than in previous periods. Such was the case in Czechoslovakia, Hungary and Poland. Data on the rise of output and productivity in the Soviet Union indicate an increase of the order of 11 to 12 per cent in industrial employment or half of that for the years 1960 to 1965. In Romania, the estimated increase in industrial employment was 23 to 24 per cent as against 34 per cent in the preceding years. Only in Bulgaria did the plan foresee a somewhat faster expansion of industrial employment than in the period before. The transfer of manpower from agriculture to non-agricultural sectors was also expected to slow down everywhere. In Czechoslovakia, Poland and Hungary, the plans foresaw a virtually unchanged agricultural labour force, whereas the decline of 4 per cent in the Soviet Union and of 19 per cent in Bulgaria represented a decrease in the rate of transfer in comparison with earlier periods.<sup>75</sup>

34. The changing demographic trends had various implications for planning. Being among the factors which determine the supply of labour, population size growth and structure became a more prominent factor in planning. Their importance was further strengthened by virtue of the fact that, since with industrial development the relation between investment and consumption became increasingly stabilized and plans stressed a more rapid growth of consumer goods production, population in its role as consumer became more relevant for planning.<sup>76</sup> The downward trend in population growth and especially the working population, together with the other factors mentioned before, constituted in principle an obstacle to rapid economic growth, either limiting the rate of expansion or increasing excessively the capital-output ratio.<sup>77</sup> In addition, because of the emerging shortages of labour, the prevailing employment policy of attaining a global equilibrium between the supply of and the demand for labour had to be supplemented by a much more differential approach, with an increased emphasis on education and vocational training and the reconciliation of specific manpower resources with specific requirements.<sup>78</sup> In more general terms, due in part to the limited contribution of the size of the labour force to further expansion, recent plans in the countries laid an increased emphasis on higher productivity through higher investments, better equipment and organization, the development of skills and so forth.<sup>79</sup> Nevertheless, in most of

the countries, net domestic product was expected to grow more slowly than in the previous period.<sup>80</sup>

(ii) *Selected countries*

35. The basic considerations in the First Five-Year Plan (1928-1932) of the Soviet Union<sup>81</sup> were the industrialization of the country, the socialist reconstruction of the rural areas and the strengthening of the socialist sector in the country's economic system.<sup>82</sup> At the same time, the directives for preparing the plan found the disproportion between the size of the working population and the possibilities of its economic utilization one of the main difficulties to be solved.<sup>83</sup> As a result of the rapidly growing demand of industry for labour, unemployment, however, had virtually disappeared in the early 1930s and, in fact, during this period some shortages of skilled labour and of specialists developed.<sup>84</sup> The Second Five-Year Plan (1933-1937) continued to emphasize industrial development to make possible the transformation of the entire economy on the basis of modern technology and technical reconstruction, but foresaw a considerably slower growth in the industrial labour force than during the first plan period.<sup>85</sup> The Fifth Five-Year Plan (1951-1955)—after the Third Five-Year Plan (1938-1942), interrupted by the war, and the Fourth Five-Year Plan (1946-1950), which was mainly a reconstruction plan—contemplated a high rate of increase of industrial production, but foresaw only a relatively small increase in the industrial working force while stressing increased labour productivity. The plan also foresaw a narrowing between the rates of growth of production of capital and consumer goods.<sup>86</sup> The slowing down of the growth of the active population, combined with limited possibilities of further transfer of workers from agriculture, had several implications. The Sixth Five-Year Plan (1956-1960) stressed technical progress

and higher labour productivity as well as an increased emphasis on the rational distribution and most efficient utilization of the labour force.<sup>87</sup> The slow natural increase in the working population would apparently be a long-term phenomenon: the Twenty-Year Development Plan (1960-1980) assumed an increase in the working population of 40 per cent, but a considerable part of this increase would be caused by rises in the over-all activity rates through the reduction of household duties and the liquidation of individual farming plots.<sup>88</sup>

36. The relevance of demographic factors for planning broadened during the 1960s as the production of consumer goods was given an increasingly prominent place in the plans. The Seven-Year Plan (1959-1965) stated as one of its objectives the proposal to meet the requirements of the population in the most important foodstuffs and to provide the population with a wide assortment of high-grade foods.<sup>89</sup> Reporting on the directives for the Eighth Five-Year Plan (1966-1970), Kosygin noted that even though farm output had increased since the five-year plans had been initiated, this growth was inadequate to meet fully the increased demand due to population growth and higher purchasing power. More generally, a rapid expansion in the production of consumer goods and a doubling of the output of those producer goods on which the production of agriculture, light and food industries, housing and trade depended was planned for this period.<sup>90</sup>

37. The first plan (1946-1949) of Poland had as its main objectives the reconstruction of war damage, the nationalization of important industries and land reform, but the chief aim was raising the standard of living of the working masses above the pre-war level. Consequently, increases in levels of consumption and in the share of the latter in total income were planned and the output of production goods was to be determined by the requirements for the production of consumer goods.<sup>91</sup> The basic task of the Six-Year Plan (1950-1955) was the establishment of socialism in Poland and the development of the capital goods industries was seen as a basic condition for creating the technical basis for socialism. The increase in industrial output would depend to a large extent on the growth of the industrial labour force and the plan predicted an increase in employment outside agriculture of around 60 per cent, or over two million people.<sup>92</sup> The Five-Year Plan (1956-1960) concentrated chiefly on the improvement of levels of living; its purpose was to raise real wages in the cities, to increase substantially the *per capita* income of the agricultural population and to remove or, at least, mitigate economic disproportion

tions. Nevertheless, for the later years of the planning period allowance was made for an increase in investments needed to ensure full employment of a rapidly growing population.<sup>93</sup> Thus, whereas, on the one hand, population growth and the rise in standards of living led to a strong emphasis on the production of consumer goods, especially in the first years of the plan, the growth of the population, on the other hand, and particularly the working force and the need to maintain full employment called for a higher level of investments towards the end of the planning period.<sup>94</sup> The Five-Year Plan (1961-1965), while stating the need for investment policy to be guided by the principle of technical progress, particularly in the heavy and the engineering industry, also stressed the necessity of making investments to increase employment even at the cost of technical progress. Population growth, especially in the working-age group, was one of the main reasons causing an increase in investment above the levels of previous periods.<sup>95</sup> The very high increase of young adults during the plan period was thought to have a number of repercussions for employment, the structure and mobility of the labour force, vocational training, and housing and educational needs.<sup>96</sup>

38. The First Plan (1947-1948) of Czechoslovakia noted the existence of labour shortages as a limit to the rate of development of the economy. It contemplated among the measures to alleviate such shortages the redistribution of workers from administration to industry, the incorporation of women, pensioners and young persons into the labour force and the use of labour reserves in the countryside.<sup>97</sup> The main consideration in the First Five-Year Plan (1949-1953) was the development and transformation of the economy, with emphasis on industrialization. The increase in the levels of living, as the chief aim of the plan, was based primarily on an increased productivity of labour. It was the latter which would make the main contribution to economic growth, since the labour force would increase only little—5.6 per cent—over the planned period. Population growth, which in general was considered the chief source of labour-force growth, would, it was estimated, make only a limited contribution to the latter's expansion during the planning period, in view of the fact that the new entrants would be drawn largely from the small generations born during the depression years. Apart from population growth, the plan relied on increased employment of women and of persons with reduced capacity, re-immigration, and the utilization of labour in backward regions through creation of employment opportunities there as additional sources of labour supply. Since the number of young persons was declining, the requirements of indus-

trial production for young skilled entrants could not be met and all production sectors had to make provision for the selection and training of workers already employed in those sectors.<sup>98</sup> For the period of the Second Five-Year Plan (1956-1960) only a relatively small increase in employment—some 7 per cent—was expected and increasing reliance had to be placed on raising the number of women and aged persons in the labour force.<sup>99</sup> The Third Five-Year Plan (1961-1965) included among its tasks the increase of productivity, which was the main factor and fundamental source of economic growth. Population growth was apparently inadequate to provide the needed new workers. Employment was to increase by 420,000 persons, approximately half of whom would be recruited from married women. In addition, agricultural employment was expected to decrease by 20 per cent, contributing to a larger shortage of agricultural labour and a deterioration in the age structure and qualifications of the rural labour force.<sup>100</sup>

## 2. THE DEVELOPED PRIVATE-ENTERPRISE AND MIXED ECONOMIES

39. Planning in the developed market economies is a relatively recent phenomenon. The first attempts at planning in these countries were the reconstruction plans in the early post-war years. One important factor in the subsequent spread of planning was the realization that the automatic market mechanism was incapable of ensuring stable economic growth and full employment, as was demonstrated in the severe depression of the 1930s. Because of the experience during these years and the development of new theoretical ideas concerning the manipulation of income, the maintenance of full employment and the welfare state, the maintenance of such conditions came to be increasingly considered as the responsibility of the central authorities, leading to an increased role of government in the economic sphere and, in turn, to the need for planning. The growing preoccupation, not only with short-term fluctuations, but with medium and long-term economic development, reinforced this trend and widened the horizons of planning in these countries. Even though a number of the developed market economies have no formal planning at all or engage in planning activities only on a very limited scale, plans as a guide for economic and social development are acquiring increasing importance in many of these countries, as well as in the developing countries.

### (a) Planning and the role of population

40. As noted before, the framework within which planning takes place and its goals differ considerably, depending on institutional and economic conditions. Planning in the developed private-enterprise and mixed

economies, as compared with that in the centrally planned economies, reflects necessarily the fact that most economic decisions in the former are in private hands and that government, while exercising control over the public sector, can influence only indirectly the course of action in private sectors. Economic plans under these conditions are mainly directed towards guiding and co-ordinating public policies and towards supplying production and investment targets without supplanting the decisions of the private sector, although consultations between the government and the private sector in plan preparation are becoming the practice in an increasing number of countries.<sup>101</sup> Differences also exist between planning in the developed market economies and the developing countries, especially as far as the objectives of planning are concerned. Whereas in the developing countries the increase in levels of income is of necessity the predominant objective, the plans of the developed market economies place much more emphasis on a broad range of goals and the balance between them. This is reflected in the nature of planning in these countries. In the developing countries it is an important tool for the transformation of the economy and society, but in the more developed countries it is rather a means of maintaining and stimulating a balanced economic growth and social development.<sup>102</sup> To these differences should be added those emanating from demographic trends. Whereas the developing countries must contend in their planning with the problems created by a rapid population growth and the predominantly unfavourable characteristics associated with it, in the developed countries, on the contrary, when demographic trends impose constraints on economic growth, they do so mostly not because population increases too fast, but because it does not increase rapidly enough.

41. In general, the main purpose of planning in the developed market economies has been described as the maintenance of the full utilization of the expanding volume of economic resources that arises out of technological progress and population growth.<sup>103</sup> More specifically, with regard to the industrialized countries of Western Europe, it was observed that Governments appeared to have the same basic objectives of full employment and a high rate of growth of national income in the context of a balance-of-payment equilibrium and domestic price stability, with most plans mentioning in addition the desirability of reducing income differentials among social groups and geographical areas.<sup>104</sup>

42. Since in most of the developed market economies population growth is low or moderate, demographic factors are thought to constitute in principle much less of an obstacle to economic growth than in those developing countries where population is increasing rapidly and

exerts a growing pressure on already scarce resources. In the developed market economies, however, population plays a role in planning precisely because its increase is slow. Demographic considerations, under these circumstances, will be relevant mainly where planning personal and "social" consumption and, especially, output, in so far as it is determined by the increase of the working population, are concerned. Since the rate of savings and levels of capital formation are already relatively high in these countries, significant increases in the share of investment, which are crucial in planning in the developing countries, do not constitute a major issue in the industrialized countries. Capital formation can thus be viewed largely as a dependent variable related to final consumer demand, while the latter can be determined on the basis of population growth and structure and levels of income.<sup>105</sup> To the extent that capital formation as well as land, which plays a relatively minor role, is not acting as a constraint on growth, the latter becomes a function mainly of the expansion of the labour force and the increase in its productivity.

43. Demographic factors may thus enter into the planning models of the developed market economies in various ways. Where demand is considered the crucial factor, such a model might take as its starting point the prospective levels of private and public demand at the end of the plan period which provide a basis for setting production targets for final consumer goods and services. Balances of labour supply and demand, of saving-investment and of international trade are then the constraints on income maximization.<sup>106</sup> Alternatively, in a supply-oriented model, estimates of the future working population and assumptions about possible changes in activity rates can be used to forecast the labour force. The estimates of the labour force, combined with certain hypotheses concerning the growth of labour productivity, yield an estimate of future output from which the values of other variables can be derived.<sup>107</sup>

#### (b) *Demographic considerations in economic plans*

##### (i) *An over-all view*

44. Generally speaking, population has not been a major factor in setting planned levels of consumption. In most plans, consumption was considered mainly a function of disposable income or, in long-term models where investment is a function of economic growth, consumption was derived as a residual.<sup>108</sup> Nevertheless, in some plans, such as that of Norway for the period 1962-1965, private consumption was mainly derived from a relationship incorporating population and product or income as explanatory variables.<sup>109</sup> On the whole, how-

ever, much more important was the role of demographic factors in setting levels of output.

45. Although in the post-war period some countries were facing employment problems due to the destruction caused by the war, conditions of underemployment which had emerged during the past (such as in Italy), or a relatively high population growth (such as in the Netherlands) in general, a slow rate of growth of the labour force has been the dominating demographic factor in the plans of these countries. Projections of the labour supply occupied an important place in planning and estimates of the future supply of labour as a function of population growth and activity rates figured prominently in a number of plans, such as the different French four-year plans and the Netherlands' long-term perspectives.<sup>110</sup> The importance of preparing future estimates of labour supply was brought out by the forecasts for Sweden for the 1961-1965 period when it was found, from a confrontation of the estimated labour supply with the demand, based on entrepreneurial plans, that the latter over-estimated the growth of labour resources, which required a downward revision of the employment and an increase in the investment objectives.<sup>111</sup> In Ireland, emigration, not the slow growth of population, was considered responsible, at least in part, for a dampening effect on activity, and the First Programme of Economic Expansion for that country emphasized the urgency of developing an industrial base which, through a rapid expansion of employment in industry, would reduce emigration.<sup>112</sup> The plans of a number of countries, such as Belgium's 1962-1965 programme, Greece's Perspective Development Plan (1960-1969) and the French perspectives, elaborated for the period 1956-1965, among others, took the future growth of the total and working populations as their point of departure and derived from the estimates thus obtained and others for labour productivity the future planned levels of national product, investment, consumption and so forth.<sup>113</sup>

46. The slow natural increase of the population in working ages, apart from constituting one of the most important constraints on setting the rate of economic growth, had other indirect effects on planning in these countries. The scarcity of labour led to an increased emphasis on the quality of the labour force, and many plans discussed vocational training and education and the conciliation of the supply of and the demand for labour force in different occupations, especially those which required more skills and training. Since employment could expand only slowly, increases in productivity became a very important factor in determining the rate of economic growth. However, rapid increases of productivity such as occurred in the early 1960s in many of the developed market economies, it has been pointed out, are likely to create, under conditions of labour scarcity,

heavy strains on the labour market and productive capacity. In order not to intensify such pressures, more moderate increases in productivity must be planned for in subsequent periods, a fact reflected in most plans for the latter part of the 1960s.<sup>114</sup>

47. Another related aspect is the increasing emphasis on determinants of the labour supply other than the growth of the population in working ages. Some plans noted the limited possibilities, in view of the pressure on the labour market, of reducing the hours of work. Other plans incorporated estimates of the effects of changes in activity rates, considering the positive effects of higher levels of female participation and the negative effects of the increase in the number of years of schooling and the decrease in activity rates at the more advanced ages. Increasing attention was also given in the plans to the possibilities of alleviating the problem of the scarcity of domestic labour by means of the immigration of foreign workers and estimates of the volume of such immigrations and their effects on economic growth have become incorporated as basic factors in a number of plans.<sup>115</sup> Finally, since the labour force was growing at such a slow pace, variations in its increase exerted considerable influence on setting the targets in planning. In the beginning of the 1960s optimistic forecasts were based in part on the expected faster growth of the labour force, due to the larger generations born in the post-war years. In addition, since this increase would consist predominantly of young workers, account was taken of the fact that while this would facilitate mobility, it might at the same time aggravate the shortage of experienced and skilled manpower.<sup>116</sup>

#### (ii) *Selected countries*

48. Demographic considerations have occupied an important place in French planning since the First Plan (1947-1951), which was a reconstruction programme for those sectors on which the recovery of the economy after the war depended. The scarcity of manpower was acknowledged to be one of the crucial factors in the development of the economy and the existence of a disequilibrium in the labour market became evident in the course of the Second Plan period (1954-1957). While as a result of the rapid development the demand for labour expanded considerably, the level of natural growth of population implied a slight decrease in the supply of labour, reinforced by the increase in the years of schooling. Only in the last year of the planning period would counteracting forces such as the reduction of unemployment to a very low level, an increase in the age of retirement and in female participation, and higher immigration become effective. Similar conditions characterized the Third Plan period (1958-1961), in which it was foreseen that the working population would remain relatively stable, despite the increase in total population. The plan conse-

quently stressed the importance of increasing productivity under the conditions of a relatively stagnant working population. At the same time, the plan noted, provisions had to be made for the education and occupational training of the large number of young people born after the war who were to enter the labour force in the course of the subsequent plan period.<sup>117</sup>

49. The Fourth Plan (1962-1965) stressed both full employment as a basic objective and the restrictions on growth imposed by the limited supply of labour and by the necessity to maintain the internal and external equilibrium of the economy. Nevertheless, the plan observed that one important change compared with previous years was the higher number of young workers who would be incorporated in the labour force. The relatively high natural increase of the labour force would have a considerable effect on labour force trends and the outlook for growth during the plan period. The tendency towards a decrease of the percentage of active population would be slowed down or halted and the labour force would expand in the plan period by some 3.4 per cent, compared with an increase of barely 1 per cent over the two previous plans. Nevertheless, the scarcity of labour in general and, especially, in certain types of occupations would continue to prevail and not allow, for instance, a decrease in working hours.<sup>118</sup> The Fifth Plan (1966-1970) noted the favourable conditions for growth created by further increases in the number of better-educated young workers. In the course of the plan period, the working population would increase at a relatively modest rate and the rejuvenation of the labour force, while implying the presence of more young workers who had not yet reached their maximum experience, would create also a dynamic climate and a change in mentality favourable to growth. Nevertheless, the scarcity of labour continued to be a restraining factor and special emphasis was placed on attempts to increase investment.<sup>119</sup>

50. Only in few of the developed countries was population growth thought to be an obstacle to economic growth; one such case was the Netherlands in the years following the Second World War. In the face of a rapid growth of the potential labour force, the problem of maintaining full employment, further complicated by the expected increase in the labour force which had lapsed as a result of the war, became an important issue in economic policy. The First Memorandum on Industrialization considered rapid industrialization and the improvement of its regional patterns in order to deal with employment problems in certain areas essential to provide work for the fast-growing population. Even such an industrialization policy was thought to be insufficient and an emigration policy was introduced as an additional measure for promoting full employment. The demographic trends had another indirect effect on planning:

<sup>117</sup> France, *Troisième plan de modernisation* ... (1959), pp. 18-23, 26-29, 79-81.

<sup>118</sup> France, *Quatrième plan de développement économique et social* ... (1962), pp. 1-2, 5-7, 108-114.

<sup>119</sup> France, Commissariat Général du Plan d'Équipement et de la Productivité, *Rapport sur les principales options du V<sup>e</sup> plan* (1964), pp. 21, 26-29, 70-72; ———, *Cinquième plan de développement économique et social* ... , vol. 1 (1965), pp. 5-6, 12; vol. 2 (1965), pp. 5-7.

wage control being the most important policy instrument, in the early post-war period at least, the success of the wage policy was attributed in part to the rapid growth of the labour force, which helped to maintain wage stability through the ample supply of labour.<sup>120</sup> The long-term perspectives for the period 1950-1970, taking as the maximum admissible level of unemployment a figure slightly over 3 per cent, estimated, on the basis of a comparison of the demand for and the supply of labour, the necessary emigration under different assumptions as to the expansion of the economy in general and exports in particular.<sup>121</sup>

51. The medium-term prognosis for the period 1965-1970, however, observed that, despite the high increase of the labour force in comparison with most other European countries, an increasing pressure on the labour market emerged in the period 1955-1965. This shortage of labour force became especially pronounced in the early 1960s even though the working population in that period, due to the post-war birth wave, increased at the high rate of 1.5 per cent annually compared with only 0.7 per cent in the years 1955-1960. As a result of the increasing scarcity of labour, the net balance of emigration changed after 1960 to an immigration balance. The projections of the working population for the 1965-1970 period, which took into account, apart from the natural increase of the population in working ages, the effects of the increased participation of females, the increased years of schooling, and immigration, showed that the share of the working population in the total, which was already very low in comparison with many other developed countries, would further decrease. The projections foresaw, nevertheless, that labour might become somewhat less scarce because of the combined influence of a somewhat possible lower economic growth and continued immigration.<sup>122</sup>

52. The solution of the unemployment problem occupied an important place in the Italian programme for the period 1955-1964, the so-called Vanoni plan. This plan is also noteworthy because it included as objectives not only the reduction of unemployment and underemployment, together with a rapid increase of income, at the rate of 5 per cent, and the elimination of the trade deficit, but also the narrowing of the gap in levels and conditions of living between northern and southern Italy. But the persistence of unemployment and underemployment was seen as the crucial problem which the economy and society had to face. Underemployment, it was asserted, was widespread and, in addition, unemployment, despite rapid economic growth, continued at high levels owing, among other factors, to the more intensive use of labour instead of the use of more labour associated with the productivity increase. The plan set out to attain a reasonable equilibrium between the demand for labour and the need for jobs as determined by the natural increase

<sup>120</sup> Weststrate, *Economic Policy* ... (1959), pp. 19-23; United Nations, Economic Commission for Europe, *Economic Survey of Europe, 1962*, part II ... (1965), chap. 3, p. 3; chap. 5, pp. 23, 25.

of the labour force and the existing unemployment and underemployment. On this basis, and within the framework of the other objectives, the plan estimated that 4 million new jobs would have to be created in the course of the plan period. This figure was reached in the following manner: new workers entering into the labour force—2 million; unemployed at the beginning of the period—1.8 million; underemployed and workers displaced by technical progress—1.7 million. In addition, 800,000 workers were estimated to have emigrated and allowance was made for frictional unemployment of about 700,000 workers at the end of the plan period, representing somewhat over 3 per cent of the active population.<sup>123</sup>

53. The Italian plan for the period 1966-1970, noting the long-term planning aims of the elimination of the major regional and sectoral imbalances, envisaged for the plan period a somewhat lower rate of growth of output than that which actually took place in preceding years, but sufficient to maintain a high level of employment. Other objectives reflected the planning goals set for the long term. Apart from an increase of national income at an annual rate of 5 per cent, the targets of the plan included an increase of social outlays up to 26-27 per cent of resources; an increase of agricultural production of 2.8 to 2.9 per cent annually—releasing some 600,000 labourers from agriculture; and an increase in employment outside agriculture by 1.4 million, of which some 40-45 per cent would be created in the south. This projected increase in employment would absorb the labour force increase as well as those workers displaced by agriculture, leaving a normal level of frictional unemployment of 2.8 to 2.9 per cent of the labour force. The starting point of the labour force estimates used in these targets was the expected population growth. Taking into account the changes in the activity rates due to increased schooling, the changes in female participation rates and the assumption that 300,000 workers would emigrate, the labour force would increase by some 600,000 persons over the plan period. With unemployment at the level indicated before, 800,000 new jobs would have to be created.<sup>124</sup>

### 3. THE DEVELOPING COUNTRIES

54. Planning for economic and social development, although a relatively recent phenomenon in the economically less advanced countries, has undergone a rapid evolution in the course of the last decades or so. In many countries the gaining of independence and the establishment of national governments were a turning point, raising the hopes and expectations of their peoples and giving them the opportunity to set out their own destiny and to formulate their own national economic and social aims. The strongest motivation for planning in the developing world as a whole was the desire to overcome the conditions of poverty and backwardness. Fostering economic and social development and achieving advanced levels of technological progress so as to obtain for their

populations the conditions of living commensurate with human dignity and the individual's development became a primary goal. Through planning, these countries undertook the formidable task of transforming their societies into economically modern and socially forward-looking nations.

#### (a) *Planning and the role of population*

55. Economic policy and planning may encompass in general a wide range of objectives including, among others, a rapid increase in total or *per capita* income, a high level of employment, a relatively stable price level, an equilibrium in the balance of payments, the reduction of marked disparities in prosperity in different regions and a diversified economy.<sup>125</sup> Despite this variety of possible goals, in virtually all of the developing countries the acceleration of the rate of economic growth necessary to overcome the economic stagnation at low levels of income is at the core of economic policy. Based on either past trends or desired future growth, plans set targets primarily in terms of total or *per capita* income even though under certain conditions income targets, it has been argued, may have to take into account other objectives or even be modified because of them. Such may be the case where serious unemployment problems exist and plans must make provision for creating sufficient additional new jobs.<sup>126</sup>

56. In the task of development, Governments and policy-makers have to face formidable obstacles. In a general sense, the rigidity of institutions, political instability, the absence of an adequate administrative capacity and a deficient infrastructure considerably hamper their development efforts. More specifically, the possibilities of attaining given levels of income or employment are limited because of the scarcity of resources. Under certain conditions, scarce natural resources constitute a serious limitation on development and its planning.<sup>127</sup> In recent years the importance of an adequate supply of trained and skilled manpower and human resources for economic development has been widely recognized.<sup>128</sup> None the

less, most development plans stress the low levels and rates of capital formation as the major constraint on planning targets. Although it is generally recognized that it would be an over-simplification to regard economic development as a function of capital formation only and that investment is a necessary rather than a sufficient condition for it, it has also been pointed out that if any one scarce factor associated with under-development should be singled out it would be capital.<sup>129</sup>

57. Raising the levels of capital formation occupies, therefore, a prominent place in the plans of most developing countries. Even so, the lack of capital constitutes in many instances a limit on plan objectives. This is especially the case in employment planning. Employment targets, generally speaking, depend on the level of capital formation and the average investment per additional worker. Given the level of total investments, maximum employment is created when, by means of the use of labour-intensive methods of production, capital outlays per worker are kept at a minimum. For several reasons, however, it is held that the feasibility of such a labour-intensive approach to development is limited. In the first place, it has been argued that the choice of methods of production is limited and that most of them require considerable capital outlays.<sup>130</sup> More specifically, the arguments are that economic development requires many projects which are capital-intensive and have only limited employment effects<sup>131</sup> and that modern technology, developed in the more advanced country where labour is often the scarce factor, is labour-saving rather than capital-saving.<sup>132</sup> In the second place, it has been asserted that in the long run both income and employment would benefit most from the most efficient, that is the capital-intensive, use of a nation's capital resources.<sup>133</sup>

58. Low productivity and under-development are closely interrelated with a structure of the economy in which primary activities dominate as at low levels of income most of the population is engaged in agricultural production to satisfy its basic needs, especially for food. Economic development, with the increased productivity it implies, is caused by and consequent upon simultaneous and interdependent shifts in the structure of employment: from primary to secondary and tertiary activities and, especially within agriculture, from less efficient to more productive activities. As has been pointed out, these changes in the production relations make it possible, on the one hand, by increasing the non-agricultural labour force, to satisfy the increased demand for non-agricultural products associated with higher levels of living. On the other hand, they create the conditions for releasing the necessary labour from agriculture through increases in productivity, while maintaining at the same time production at levels high enough to satisfy the demand for agricultural products.<sup>134</sup>

59. Industrialization in the sense of the structural transformation of the economy thus constitutes a key factor in rapid economic growth and most plans have accepted rapid industrial growth as the central feature of long-term economic growth. The emphasis on industrial development planning responds to the nature of these sectors as the leading ones in economic development as well as to the argument that only industries and the other non-agricultural sectors are capable of absorbing the surplus rural population. In discussions on priorities of development, however, it has also been argued that agricultural development is primary since the rate of industrialization depends fundamentally on the rate of expansion of agricultural production. Not only, it is asserted, is the demand for food at low levels of development more urgent, but, in addition, industrialization requires increased agricultural productivity in order to release labour from the land and to feed the increasing

*ment* ... (1959), pp. 330-333; Mahalanobis, "Some observations ..." (1953) and his *Talks on Planning* (1961), pp. 9 ff., 13 ff., 95, stressed in this connexion, especially, the need for investments in capital goods production. See also Dhar, "Heavy industry ..." (1962) and Banerji, "Growth of investment ..." (1962). For views favouring capital-saving investments and labour-intensive techniques, see Buchanan, *International Investment and Domestic Welfare* (1946), p. 24; Kahn, "Investment criteria in development programs" (1951); Chenery, "The application of investment criteria" (1953); Nurkse, *Problems of Capital Formation* ... (1953), p. 35. Several studies have pleaded for an appropriate blending of capital-intensive and labour-intensive techniques; see, for instance, United Nations, Economic Commission for Latin America, *Economic Development Planning* ... (1961), p. 32; Seth, *Theory and Practice* ... (1967), pp. 104-109. For a general discussion of the issues involved, see also International Labour Office, *Employment and Economic Growth* (1964), pp. 130 ff.; Caire, *La planification* ... (1967), pp. 443 ff.; Singer, *International Development* ... (1964), pp. 75 ff.; Das-Gupta, *Planning and Economic Growth* (1965), pp. 53-54. See also chapter XIII, sections C and D.

non-agricultural population and provide it with the necessary raw materials. Nevertheless, in general, it has been accepted that the planning of both agricultural and industrial development should complement each other in such a manner that the productive capacities of both sectors are utilized to the fullest possible extent.<sup>135</sup>

60. Any effective development plan, therefore, will have to consider the transfer of labour from agriculture into the industrial sectors and formulate employment targets accordingly. Whereas the long-term employment aspect of planning for industrial development is to provide productive work for an increasing labour force, the immediate employment considerations concern the mobility of labour and the efficient absorption of the existing industrial labour force and the additions to it through natural growth and migration. Although the view is found that as a general principle industrial planning should favour labour-intensive development so as to create the highest possible employment, the more general opinion is that industrial development does not require much labour and adds little to employment.<sup>136</sup> The limited employment objectives of most plans for industrial development and their failure in many cases to absorb the existing supply of labour has led a number of experts to stress the importance of providing additional jobs through special programmes, especially in rural areas, whose effect would also be to reduce the excessive inflow of rural labour into the urban labour market.<sup>137</sup>

61. Demographic considerations are involved in a number of ways in planning for economic development. For the past few decades the majority of the developing countries have experienced or are experiencing a significant acceleration in the rate at which their populations grow, as a result of declining levels of mortality accompanied by persistent high levels of fertility, the latter also being the main determinant of the "young" age distribution. Unprecedented high rates of population growth have become typical for the majority, though not all, of the developing countries. An inquiry on the implications of population growth for economic and social development

<sup>135</sup> For the different viewpoints and their discussion see United Nations, *Processes and Problems of Industrialization* ... (1955), pp. 2-3; United Nations, Economic Commission for Asia and the Far East, *Programming Techniques for Economic Development* ... (1960), pp. 19, 30; ———, "A decade of development planning ..." (1965), pp. 46, 54.

<sup>136</sup> United Nations, Economic Commission for Asia and the Far East, "Problems of industrialization ..." (1958); United Nations, *Report of the United Nations Seminar on Industrial Programming* ... (1964), pp. 7-9; United Nations, Economic Commission for Latin America, *The Process of Industrial Development* ... (1965), pp. 42 ff.; Rivkin, "The role and scope of industrialization ..." (1965). See also chapter XIII, sections C and D. It has, however, also been noted that in developing countries a bias towards a more than optimal use of capital-intensive methods of production may exist. International Labour Office, *Employment and Economic Growth* ... (1964), p. 136.

<sup>137</sup> Oshima, "A strategy for Asian development" (1962); International Labour Office, *Employment and Economic Growth* (1964), pp. 132, 156-172; United Nations, *World Economic Survey, 1959* (1960), pp. 124-125; ———, *World Economic Survey, 1964*, part I ... (1965), pp. 66-67; Mahalanobis, *Talks on Planning* (1961), p. 69; Singer, *International Development* ... (1964), pp. 99 ff.

found that "many of the responses from Governments of the developing countries manifest more or less serious concern with the high rates at which the population of their countries is increasing, considering this a serious handicap to economic and social development".<sup>138</sup>

62. High rates of population growth do not imply only the need for income to grow faster in order to gain a rise in levels of living; they also contribute to a deterioration in the relation between population and other resources. With respect to the main components of income, consumption and investment, it has been noted that the rapid growth of population in most of the developing countries makes the primary task of maintaining *per capita* consumption in itself considerable. It also requires large capital outlays, the so-called demographic investments, only to prevent the existing levels of living from declining.<sup>139</sup> In practice, economic growth cannot take place without any growth in *per capita* consumption while future development depends on raising the levels of capital formation. Therefore, the growth of income must surpass that of population by a substantial margin. To these effects of population growth must be added the adverse consequences of the "young" age distribution in the developing countries with its high dependency ratios, which affect savings and productive capacity as well as the composition of investment with a relatively large share of investments that are not directly productive, such as education, health, housing and so forth.<sup>140</sup>

63. Demographic factors are especially prominent in the case of employment planning. Fundamentally, the setting of employment targets must depart from the projected labour-force growth. In many of the countries under consideration where the labour force is expanding rapidly and unemployment and underemployment frequently are already high, planning for full employment meets many obstacles. Even where investments and other resources are allocated in such a manner that they would create the highest possible employment—implying low ratios of capital and land to labour and the use of labour-intensive methods of production—low levels of investment and scarcity of land in many cases preclude the possibility of attaining full or satisfactory levels of employment. Since, as noted, the opportunities for labour-intensive techniques are limited and development plans are generally productivity-oriented rather than employment-oriented, the employment objectives in development planning, it has been observed, are as a rule necessarily limited.<sup>141</sup> Attempts at increasing employment rapidly are further hampered by the fact that although an over-all

<sup>138</sup> United Nations, *Inquiry among Governments* ... (1960), p. 8.

(1969), pp. 55 ff.; United Nations, *World Economic Survey, 1964*, part I ... (1965), pp. 64-65. Several writers have noted that even if capital was allocated so as to create maximum

(Continued on next page)

labour surplus exists, there is a shortage of qualified and skilled manpower; this acts as a constraint on the rate of development as well as on employment expansion.<sup>142</sup> Because the employment generated directly by the planned development remains far short of the increased supply of labour associated with a rapid population growth, a number of plans contemplate special programmes to expand productive employment which would require little additional investment. More jobs can be created, it is asserted, through fuller utilization of existing capacity or by promoting various types of labour-intensive projects.<sup>143</sup>

64. Planning the industrial and sectoral development of the economy is to a considerable extent conditioned by demographic factors. Rapid population growth in developing countries signifies, according to various authors, for various reasons an obstacle to rapid industrialization. To the extent that it depresses income, it will slow down capital accumulation and the expansion of markets for manufactured products. While holding back the development of the industrial sectors, rapid population growth, together with the high income elasticities of demand for food at low and stagnant levels of income, will require large increases in the supply of agricultural commodities.<sup>144</sup>

65. In planning the development of industry and, especially, agriculture, the relationship between population and agricultural land or resources, included in the general programmes, emerges as an important factor. Differences in agricultural density, as has been frequently noted, may affect the development of agriculture as well as the timing and sequence of the industrialization process. In countries where population density and the agricultural labour-land ratio are high, prospects of raising agricultural production through the extension of the area under cultivation or more intensive exploitation of the land already under cultivation are much more restricted than in low-density countries.<sup>145</sup> In countries with high rural density, it is argued, a prerequisite for agricultural development is the transfer of part of the agricultural labour force from the land before any attempts to increase productivity in this sector can be expected to bear fruit. In low-density countries, on the contrary, raising the levels of agricultural productivity is a necessary condition

for the release of labour from the land and for supplying the non-agricultural population with the necessary food and raw materials. Whereas thus in the latter case the increase of agricultural productivity would be a pre-condition for industrialization, in high-density areas planning for industrial development should concentrate primarily on creating additional employment opportunities in the non-agricultural sectors so as to absorb the surplus rural population.<sup>146</sup>

66. Among the demographic factors directly associated with the industrialization process and the planning of industrial development, the occupational and geographical mobility of the population is of crucial importance, the redistribution of the population from predominantly rural-agricultural to urban-industrial areas and occupations is both a condition and a consequence of the development process. Urbanization and industrialization are closely linked to each other. For technological and organizational reasons, the concentration of workers in urban areas is a virtually necessary concomitant of the process of industrial change and the changes in conditions and standards of living; the diversification of the demand and so forth are, in turn, directly related to the urban way of life.<sup>147</sup> However, the experience of the developing countries, in particular, has shown that the two processes are not necessarily balanced. The rapid growth of urban populations, frequently at a rate faster than that warranted by the pace of industrialization, it is held, are a basic factor in the urban employment problems in many developing countries.<sup>148</sup>

67. Within the context of industrial development planning, employment policies have to take into account not only the over-all growth of the labour force, but also its spatial and occupational change. With the large displacements of labour from agriculture to non-agricultural activities, typical of many developing countries, the primary task of employment planning, it has been argued, must be the creation of additional job opportunities in industry and related sectors. Even though in a number of these countries agriculture could conceivably absorb additional workers, any effective industrialization policy must provide, according to this view, for the increase of non-agricultural employment, which would absorb the rapidly growing labour force as well as the underemployed rural labour.<sup>149</sup> Employment objectives formulated on

employment, the available capital resources might still be insufficient to create full employment—see Higgins, *Economic Development* ... this basis, however, would, in the view of others, often clash with the promotion of higher productivity as an essential ingredient of industrialization. In general, it has been asserted that industry can play only a relatively minor part in the direct absorption of the redundant labour force. Modern industrial processes, as noted in the preceding pages, are for the most part highly capital intensive, requiring comparatively little labour and thus have only a limited impact on creating new jobs.<sup>150</sup> The employment problems arising in the course of an industrialization programme, due to high population growth and an excessive inflow of workers in the non-agricultural labour market, have focused attention on the possibilities of creating additional employment through special programmes designed to the expansion of rural jobs, which would also constitute a check on unduly large migrations to the cities. Among the areas considered for action in this respect are: cottage and small-scale industries, rural works programmes, including such works as digging wells, building rural roads, terracing land and so forth.<sup>151</sup>

(b) *Demographic considerations in economic plans*

(i) *An over-all view*

68. The rapid growth of population in the developing countries has been a significant factor in the setting and implications of targets for economic growth both at the international and national level. The proposal for the First United Nations Development Decade suggested a minimum rate of growth of aggregate income of 5 per cent as a goal to be reached at the end of the Decade. Such a growth rate would permit, assuming a continuation of the then prevailing rate of population increase in the developing world, a doubling of the levels of living within a period of 25 to 30 years. The growth rate of 5 per cent annually, however, would not permit a very rapid rate of increase in *per capita* income in those countries where population was growing most rapidly.<sup>152</sup> The action programme for the Second United Nations Development Decade set as objectives for the developing countries a rate of expansion of at least 6 per cent in total and 3.5 per cent in gross product per head. This objective was based on the assumption of a 2.5 per cent average annual increase of population. This rate, being below that actually forecast for the 1970s, suggests the measures each developing country should formulate for its own demographic objectives within the framework of its development plan.<sup>153</sup> In a study discussing the plans of thirty-eight developing countries, it was noted that the high rates of population growth were an important factor in setting high planned rates of growth of domestic pro-

duct, which in no case was below 4 per cent and for the majority was 5 per cent or more.<sup>154</sup>

69. Rates of population growth of the order of 2 to 3 per cent were also at the basis of the high planned increases in total consumption of 4 to 5 per cent. Since at the same time most plans projected high marginal saving ratios, which might prove to be difficult to attain if population growth were to be more rapid than foreseen, the necessary rate of growth of income would be very high.<sup>155</sup> Population growth, together with the high income elasticity of the demand for food—estimated at about 0.8—and the aim to reduce the dependence on imports, accounted for the rapid acceleration in the growth of agricultural production envisaged in most plans. Since in a number of countries agricultural production had failed to keep pace with the growth of population according to the study cited, agricultural plans made to an increasing extent allowance for the influence of demographic factors. Because of the high rates of growth, for instance, an increasing emphasis was placed on agricultural and food production for the domestic market instead of that on export crops.

70. Many of the plans for the agricultural sector also reflected the implications of population density on the planning outlook, particularly for the possibilities of increasing or not the area under cultivation and for capital requirements.<sup>156</sup> While almost all plans reviewed in the study contained targets for the output of industry, the details with which these plans were elaborated varied greatly. Estimates for final and intermediate goods by the main branches of manufacturing industries were normally based on targets for consumer expenditures, as well as on information about the income elasticity for various products and on knowledge of input requirements of other industries.<sup>157</sup>

71. The role of employment planning in development programmes varies widely. In many countries employment has tended to be given a more or less residual role in the actual process of development planning. Where employment targets are formulated, they are frequently relatively modest and plans have considered full employment mostly a long-term objective.<sup>158</sup> The deterioration over the past few years of employment conditions, when in many developing countries the increase in income has far outpaced the rise in productive employment, has suggested the necessity for assigning a higher priority to employment creation than in the past. It is on this basis that proposals have been made for a world employment programme at the centre of which is the principle of development through fuller employment.<sup>159</sup>

<sup>159</sup> International Labour Office, *The World Employment Programme* ... (1969), especially chap. 2.

72. The extent to which employment is an often neglected aspect of planning was indicated in an earlier cited study. Of the thirty-eight countries considered, about two thirds estimated the likely increase in the labour force, but only twelve formulated specific targets for increases in non-agricultural employment and only a few agricultural targets in a systematic manner.<sup>160</sup> According to this study, in those cases where industrial employment estimates were prepared, they were mainly derived from the planned increase in output or investment in the industrial sectors. Most developing countries in their plans have assumed that the rate of increase in non-agricultural employment would substantially exceed the rate of increase of their labour force. In spite of this, the expected increase in the total labour force in almost all countries has been greater than the additional employment opportunities foreseen in the non-agricultural sector so that in the absence of a significant expansion of agricultural employment, the absolute number of unemployed or underemployed would increase over the plan period. The recognition of this limited effect of industrialization programmes has led to an intensified search for employment creation in other fields, including rural areas, through small-scale industries and cottage industries, additional construction activities and so forth.<sup>161</sup>

73. As far as plans were concerned where employment was considered as a distinct target, even though limited by the total resources available, it was found that, generally, the setting of the employment target was guided by the projected increase in the labour force. Of the twenty-six plans for fifteen countries, some of which had reached a fairly high level of development, only two set targets lower than the expected increase in the labour force. But altogether in sixteen plans the projected increase in employment was equal or only slightly above that in the labour force. Even so, in many of these cases plans had to be adjusted or revised or special programmes had to be introduced in order to meet the employment targets. In many instances, it was found, the employment targets would thus not decrease significantly the serious employment gap typical of many developing countries.<sup>162</sup>

#### (ii) Selected countries

74. The role of population in planning the general rate of development was recognized in the early plans of those Asian countries, particularly India, which were among the first of the developing countries to initiate economic planning. In India's pioneering First Five-Year Plan the rate of population growth was included, next to the rate of capital formation and the marginal capital-output ratio, as one of the main factors in estimating possible rates of development. The plan stressed the strategic role of capital formation, but also noted that population growing at a certain rate would require an increase of income at the same rate merely to maintain

existing levels of living, which meant that not only would so much less of the additions to national income be available for ploughing back into investment, but a part of what was ploughed back would be taken up by capital equipment required for maintaining *per capita* income in the subsequent period.<sup>163</sup> The Second Five-Year Plan, noting that although the rate of population growth in India was estimated to be not higher than in some of the advanced countries, stated that the estimated annual growth—of some 4.5 to 5 million persons—represented a large increase in terms of the resources required to maintain even existing levels of living.<sup>164</sup> The acceleration of the rate of growth of population, characteristic of many of the developing countries, according to the Third Five-Year Plan, had substantially affected the performance of the 1950s—despite a large increase in total income, income per head experienced in this period only a moderate increase of 16 per cent—as well as the long-term perspectives.<sup>165</sup>

75. The problem of employment planning received special attention in the plans of India. The First Five-Year Plan, while pointing out the possible advantages of large resources of unutilized or underutilized labour force and the increase of manpower accompanying a growing population, also stressed that in the initial stages of development the scope for directly utilizing such manpower was limited and, whereas the plan contemplated various measures for alleviating the problems of unemployment and underemployment, their elimination in an under-developed country such as India was by its nature regarded as a long-range problem.<sup>166</sup> The Second Five-Year Plan concluded that in the first plan period employment opportunities had not been increasing *pari passu* with the labour force and that, in addition to the 10 million jobs to be created for the expected increase in the labour force in the course of the second plan, a backlog of unemployment estimated at 5.3 million existed. While acknowledging the desirability of introducing employment-creating, labour-intensive techniques, the second plan also argued that the limited choice of techniques and the probable negative effects of the use of labour-intensive

<sup>163</sup> India, Planning Commission, *The First Five-Year Plan* (1952), pp. 12-19.

<sup>164</sup> India, Planning Commission, *Second Five-Year Plan* (1956), pp. 5-7.

<sup>165</sup> India, Planning Commission, *Third Five-Year Plan* (1961), pp. 20-21, p. 750. Provisional results of the 1961 population census showed a population considerably higher—by 7 per cent—than the projections used in the Second Five-Year Plan. In the First Five-Year Plan it was estimated, assuming a continued population growth of 1.25 per cent annually, that *per capita* income could be doubled by 1977. In the long-term perspective prepared at the time of the Second Five-Year Plan, a slightly higher population growth was assumed, but in view of a better than expected performance of the economy in the preceding five years, the doubling of *per capita* income was expected to occur by 1973-1974. However, in the Third Five-Year Plan, earlier population projections had to be substantially revised and a rate of growth of population of 2 per cent was foreseen. Although the original estimates of growth of income were increased from about 5 to nearly 6 per cent annually, the plan stressed that it would be very difficult to fulfil the aim of doubling *per capita* income by 1973-1974, as proposed at the time of the Second Five-Year Plan.

<sup>161</sup> United Nations, *World Economic Survey, 1964*, part I ... (1965), pp. 64 ff.

<sup>162</sup> Hsieh, "Planned rates of employment increase in development plans" (1968).

techniques on savings and investments reduced the possibilities for actually using such measures extensively, the more so in view of the high priority given to capital-intensive heavy industry. The employment targets set out in the Second Five-Year Plan were, therefore, relatively modest: the plan contemplated the absorption of the new entrants into the labour force, as well as relief of some of the existing underemployment, without solving the employment problem.<sup>167</sup> In the course of the second plan period, however, the employment situation suffered a further deterioration, according to the Third Five-Year Plan, and the high rate of population growth, as revealed by the data of the 1961 population census, implied that the employment situation had become increasingly complex. Despite the significant additional employment created in the course of the earlier plans, by the end of the second plan the unemployment backlog had increased to 9 million persons, while a further 15 to 18 million were estimated to be underemployed. In order to prevent a further deterioration, the minimum goal of planning should be to absorb at least the equivalent of new entrants into the labour force. Nevertheless, as a result of the sharp increase of population, the expected number of new entrants—17 million—in the third-plan period was higher than the projected increase in employment—14 million—and a special need existed, therefore, to create additional employment by various other means, such as rural industrialization and rural-work programmes.<sup>168</sup>

76. The role of population in planning development was also emphasized in the national plans of Pakistan. The First Five-Year Plan noted the existence of a serious population problem facing the country and both the pressure of population on other productive resources as well as the impact of the rapid growth of population on development were stressed in the Second and Third Five-Year Plans.<sup>169</sup> However, the lack of population and labour force data at the time the earlier plans were formulated did prevent the incorporation of demographic variables into the plans. One of the main problems created by the rapid growth of population was that of employment. According to the estimates of the Third Five-Year Plan in the 1950s, less than 70 per cent of the labour force increase was absorbed, but a relative improvement took place in the course of the second plan period when employment expanded fast enough to absorb nearly the whole labour force increase of that period.<sup>170</sup> Population growth was an important consideration in the perspective plan for Pakistan (1965-1985), formulated at the time when the Third Five-Year Plan was prepared. While over the twenty years considered, a rate of growth of total

income of 7 per cent annually was considered feasible, the attainment of the proposed increase of *per capita* income of 4 per cent annually was considered very much contingent on the future growth of population. Although population at the time the perspective plan was formulated was assumed to increase by 2.6 per cent annually, planned improvements in health facilities and nutrition were thought to lead to a continued rapid decline of mortality and, unless population growth was checked by a fall in fertility, it was likely to increase to over 3 per cent, thus jeopardizing the increase of 4 per cent annually in *per capita* income.

77. Demographic considerations occupied an important place also in Ceylon's Ten-Year Plan. According to the plan, the continuation of the relative advantage which Ceylon enjoyed in comparison with most of the other countries of the region as a result of a relatively advanced plantation economy would depend to a great extent on the future growth of population.<sup>171</sup> While discussing various implications of rapid population growth for development, the plan emphasized especially the unfavourable effects on investment, since high population growth tends not only to increase consumption needs faster and so reduce the rate of investment, but also requires a high proportion of the available investment resources to be diverted to the social needs arising from population growth, thus limiting the directly productive investments. Unlike the experience of the Western countries, according to the plan, there is no certainty that the decrease in mortality will be followed by a lowering of fertility, as the rapidly growing population may offset the effects of economic growth so that the socio-economic changes, which are a prerequisite for a decline in fertility, will not take place. In Ceylon, the plan states, low levels of development exist alongside chronic unemployment and an excessive pressure of population on land and other resources.<sup>172</sup> Even if the birth rate declined, this would not significantly affect the labour force during the first decade and a half after its onset and rates of economic growth which would be sufficient to raise levels of living substantially then might not necessarily ensure full employment.<sup>173</sup>

78. The implications of population growth and characteristics have also been discussed in the plans of various other Asian countries, although the importance attributed to demographic factors varies greatly. The Second Five-Year Plan of the Federation of Malaya drew attention not only to the consequences of the high rate of population growth—over 3 per cent annually—for the forced pace of economic growth required to keep up only with the increasing needs for goods and services, as well as employment, but also to the high pressure of population on the land and the rural overcrowding.<sup>174</sup> The Third Four-Year Plan (1961-1964) of China (Taiwan) also noted that the high rates of population growth posed a

<sup>167</sup> India, Planning Commission, *Second Five-Year Plan* (1956), pp. 5-6, 26-27, 110-114, 124. For a discussion of employment considerations in India's Second Five-Year Plan and their background, see also Robinson, "India 1955: unemployment and planning" (1965).

serious threat to economic development, but added that an increasing awareness by the general public of the population problem had led to a growing self-restraint, lowering fertility; the high increase of population was therefore expected to slow down in subsequent years.<sup>175</sup> The plans of some other countries of the region, however, took the demographic factors for granted and apparently considered them less serious as obstacles to their development. The Second Four-Year Plan of Burma stated that unemployment had not been as serious a problem in Burma as in such countries as India or Pakistan. However, it recognized the fact that, with the increase in labour force over a longer period, unemployment might become serious and more labour-intensive production methods should be preferred. Nevertheless, even though the rate of growth of population was expected to accelerate, the additional employment to be created according to the long-term objectives would be considerably higher than the requirements resulting from labour force growth.<sup>176</sup> The three-year and five-year plans of the Philippines stressed the employment problems the country faced, but took the high population growth for granted and devoted little attention to demographic aspects.<sup>177</sup> But the implications of population growth for employment and economic development in general, as well as specific aspects, were the subject of a joint study of the United Nations and the Government of the Philippines.<sup>178</sup> The acceleration of the rate of population growth in some of the countries of the region affected the performance of the plan. In the case of Thailand, for instance, the rate of growth of income for the years 1961-1963 was higher than the planned target, but owing to a higher increase of population than expected, the *per capita* growth of income remained below the planned rate.<sup>179</sup>

79. Whereas in Africa some planning activities, especially as regards the funds reserved by the metropolitan areas for the dependent territories, go back to the colonial period, planning underwent a rapid development only during the later stages of this period and particularly after independence was attained. Although the idea of planning has been firmly established in the region, lack of information and data, especially on population, continues to hamper development planning seriously in these countries and many of the plans formulated are only partial.<sup>180</sup> In the First Five-Year Plan (1963-1967) of Somalia it was noted, for instance, that apart from data on product, other statistics—including those on population, birth and death rates, age distribution, immigration and emigration, labour force, employment and unem-

ployment—were either not available or not reliable.<sup>181</sup> In Ethiopia, in the absence of a population census, population estimates for the Second Five-Year Development Plan (1963-1967) had to be based on an old population count and two sample surveys.<sup>182</sup> Population figures, where available, often become very crucial for other estimates even though other data are lacking. In the First National Development Plan (1966-1970) of Zambia, agricultural production targets were derived, for instance, from estimates of the active rural population and levels of consumption.<sup>183</sup> In the case of Ghana, the projected demand for food was based on nutritional standards and population.<sup>184</sup>

80. The Ten-Year Plan of the United Arab Republic, which aimed at doubling real income between 1960 and 1970, noted the problem of unemployment and underemployment and the existence of a labour surplus. In view of the continued rapid growth of population, such underemployment as existed was thought likely to increase, especially in agriculture, which would need to absorb a number of workers much in excess of the estimated requirements. Therefore, the plan provided for additional investments in small enterprises in the non-organized business sectors, and especially for the development of rural areas.<sup>185</sup> The problems posed by the fast acceleration of population growth for economic development and employment were considered in detail in Morocco's Five-Year Plan for 1960-1964. In view of the rapid population growth and the existing backlog of unemployment and underemployment, the problem of the absorption of the labour force was one of the central issues of the plan. The estimated total future employment—based on estimates of net investment and unchanged production techniques distinguishing between the traditional-subsistence sector and the modern-market sector—fell appreciably short of the expected increase in the labour force—the latter was estimated to increase by 90,000 persons annually in comparison with 80,000 new jobs to be created under the programmes envisaged in the plan—and the plan also foresaw the need to take additional measures aimed at increasing employment.<sup>186</sup>

81. Population pressure and growth also had an overbearing influence on the development programmes of Mauritius. The so-called "Meade report" asserted that the future of Mauritius, in view of the limited extension of the island and the predominantly agricultural character of its economy, was dominated by its population. increase in the rate of growth of population since the pre-war period and the existing pressure of the population on the land were thought to have been contributing factors in the decline of levels of living observed at the time.<sup>187</sup> Both the Five-Year Capital Expenditure Plan (1957-1962) and the Five-Year Plan (1960-1965) considered the demographic aspect fundamental for future development. The earlier plan noted that the growth of population was the main problem facing Mauritius in the struggle for development and that, since the decision to solve the problem of overpopulation must be found in the social conscience of the people themselves, in the absence of a response to the existing social conditions, the aim of planning in Mauritius should be, as prospects for large-scale emigration were also considered limited, to delay the effects of high population growth on levels of living.<sup>188</sup> The Five-Year Plan for 1960-1965 proposed, in order to cope with the population problem, to encourage, apart from a diversification of the economy, the growth of new secondary and labour-intensive industries.<sup>189</sup>

82. Ghana's Seven-Year Plan (1963/64-1969/70) affirmed that a growing population presented an opportunity as much as a problem for economic development. Population growth not only implies more needs, but also a higher productive potential through the increase in the working force. However, according to the plan, a sustained stream of productive investments is required to turn this opportunity into reality, while, on the other hand, a young and rapidly growing population implies a high dependency and a heavier burden of savings on the working population. The long-range perspective plan placed special emphasis on the rapid growth of the labour force of the country and the problem of employment. Each year, over 70,000 additional workers would have to be employed, but in the six years between 1955 and 1961 the leading sectors provided work only for some 100,000 additional workers. Although the Seven-Year Plan aimed at substantial improvements in the employment situation, it was also recognized that full employment would only be reached after many years of sustained economic growth.<sup>190</sup>

83. In other African countries, either because population settlement is relatively scarce and no pressure of population on natural resources exists or because population increases at moderate rates, demographic factors are not considered a serious obstacle to economic development. Nigeria's Development Plan for 1962-1968 stated that, although population was growing rapidly, there were still large areas of the country which remained to be opened up and developed. Nevertheless, demographic considerations were not absent from the plan. In setting a lower limit of growth of income of 4 per cent and in determining the investments required to attain this level,

account was taken of the fact that at this rate of economic growth consumption would increase at 2.8 per cent annually, a rate which would hardly exceed that at which population was increasing.<sup>191</sup> In Ethiopia's Second Five-Year Plan (1963-1967), the rate at which population was estimated to grow—2 per cent annually—was viewed as encouraging both from the point of view of the availability of labour force and the extension of the domestic market, the more so since Ethiopia was a sparsely settled country. On the other hand, the plan recognized that under the prevailing levels of income and lack of trained personnel, it would be impossible to provide the population, as one of the most important factors in development, with the desired education, health protection and essential facilities at an early date.<sup>192</sup>

84. The need for a development planning policy in Latin America has been recognized for some time, but most of the earlier plans date back only to the late 1950s or the beginning of the 1960s. The adoption of the "Carta de Punta del Este" signified an important step towards the progress of planning in this region. According to Urquidí, it was generally held that development planning in Latin America should be based on the need to make more efficient use of resources, to stimulate import-substitution activities and to meet basic social needs. The population expansion—the scope of which has only recently been realized—has not so far been a determining factor in such changes, but unless population trends can be significantly altered, they will assume first-rank importance in the future.<sup>193</sup> Much of the discussion on demographic factors in plans for the countries of this region have focused on employment aspects. In the case of Ecuador, a study setting out the bases and guidelines for development planning stressed the implications of population growth for employment and considered the creation of job opportunities as one of the main problems facing the country. Specifically, it proposed that in order to promote fuller employment, public investments should be oriented towards labour-intensive projects. As in many other countries of the region, the problem of insufficient employment and the need to create additional jobs in the non-agricultural sectors were stressed.<sup>194</sup>

85. The development plan for 1963-1966 of Venezuela, while noting the high rate at which population was increasing, took a positive view, in general, of the effects of population growth. While asserting that human resources are the most valuable asset of a nation, the plan also recognized that the creation of sufficient employment opportunities was also among the main tasks of planning. However, the estimates of future growth of the economy, based on historical trends, revealed that despite a high rate of growth of income, employment would expand at a rate only slightly higher than the expected labour force

growth during the plan period. Consequently, the high level of initial unemployment—14.2 per cent in 1962—would decrease only slightly—to 13.7 per cent in 1966—showing that the continuation of past trends would not significantly contribute to the solution of the employment problem. Additional programmes, such as substantial increases in projects for the construction of low-cost housing, training of workers, formation of technical personnel, as well as a higher increase of employment in the service sectors, were expected to reduce unemployment to a more acceptable level of 6.9 per cent by 1969.<sup>195</sup>

86. Colombia's general plan for economic and social development identifies three main demographic problems: the high growth rate of the population; the even more rapid increase of the urban population, especially of the large cities; and the problem of the absorption of the labour force at satisfactory levels of productivity. The rate of economic growth proposed in the plan would not solve the employment problem which, as the result of rapid urbanization, would become especially pressing in the non-agricultural sectors. As areas of public policy contributing to the solution of the problem, the plan suggests the possibility of increasing the economic capacity of the smaller and intermediate cities, thus diverting migration from the large cities, and that of a special effort in the field of education and orientation of the persons about to enter the labour force.<sup>196</sup>

### C. Planning for education, health and housing

87. Planning for education, health and housing forms part of what is often referred to as planning for the social sectors as distinguished from economic planning.<sup>197</sup> However, as has been noted before, the validity of such a distinction and separation between social and economic planning has been questioned and the necessity of integrated planning encompassing both economic and social sectors is being increasingly accepted. It is generally recognized that for balanced social and economic development, the expansion of social services should proceed in some reasonable relationship to economic growth and that, in the allocation of resources, sufficient consideration should be given to the basic relationships between economic and social development.<sup>198</sup>

88. In a general sense, "social planning" may be said to convey two aspects both closely related to economic planning. In the first place, it encompasses social policy

<sup>195</sup> Venezuela, Oficina Central de Coordinación y Planificación, *Plan de la nación, 1963-1966* (1963), pp. 8, 11-12, 55.

<sup>196</sup> Colombia, Consejo Nacional de Política Económica y Planeación, *Plan general de desarrollo económico y social, primera parte* ... (1962), pp. 290-292.

<sup>197</sup> Planning for these sectors, although they are among the most important and most directly affected by demographic factors, does not exhaust the field of social planning. Other "social" sectors include, among others, social welfare and social security, levels of living and income distribution, labour policies and programmes etc.

<sup>198</sup> See the introductory part of this chapter, also United Nations, *International Survey of Programmes* ... (1955), p. 7; ———, *Report on a Co-ordinated Policy Regarding Family Levels of Living* (1957), p. 18; ———, *The United Nations Development Decade* ... (1962), pp. 2-3.

as part of development planning as a whole, which establishes social norms with respect to the allocation and utilization of resources and the distribution and use of the society's output and wealth. In the second place, it involves sectoral planning of what are usually referred to as social services such as education, health, housing and so forth.<sup>199</sup> In practice, planning covers both economic and social aspects and most plans include goals and objectives which are at the same time both economic and social: higher levels of living; high or full employment; the distribution of income and so forth.<sup>200</sup> Economic and social aspects are also closely related where the planning of social sectors is concerned. Not only does planning for these sectors contribute directly to improvement in the quality of life, which is the ultimate goal of development, but many of the social objectives are also important factors in promoting economic development.<sup>201</sup> It is for these reasons that social change and economic strategy have become recognized as both forming part of a single strategy of development.<sup>202</sup>

89. Even though in practice planning is concerned with both economic and social aspects, no over-all conception and theory of balanced social and economic growth and development exists and the integration and co-ordination of the economic and social fields in plans is in many instances still far from complete and the same holds for the social sectors considered by themselves.<sup>203</sup> Where a conflict between more strictly economic objectives and social objectives exists, priority has often been given to the former, partly, it is argued, because of the necessity to attain certain economic goals before social objectives can be reached.<sup>204</sup> The view is sometimes also found that in social planning priority should be given to those programmes that have the most direct effect on productivity.<sup>205</sup> As a result, allocations for development in the social sectors may tend to take the form of

<sup>199</sup> Twelfth International Conference of Social Work, "Report of the pre-conference working party to the Twelfth International Conference of Social Work" (1965).

<sup>200</sup> United Nations, *Report on the World Social Situation* ... (1961), pp. 82-86; United Nations, Economic Commission for Africa, "Some problems of social development planning ..." (1962); United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963); Tinbergen, "Social aspects ..." (1965). The interrelation between social and economic aspects is especially close in community development planning, which combines social projects, such as education and health, with economic ones, such as agricultural development.

<sup>201</sup> United Nations, *Report on the World Social Situation* ... (1961), pp. 33-34, 85; ———, *Planning for Economic Development* ... (1963), p. 17; United Nations, Economic Commission for Africa, "Some problems of social development planning ..." (1962).

<sup>205</sup> United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963).

residual financing where these sectors are considered only after the claims of economic sectors have been established.<sup>206</sup> The lack of a theory of balanced economic and social development is in part responsible for such conditions, but the formulation of such a theory encounters various obstacles. In the first place, the influences of different economic and social factors upon each other are only incompletely or poorly understood and, secondly, no objective or rational common bases exist for measuring and comparing economic and social development in general or social planning in its different aspects.<sup>207</sup> The absence of well-defined methodologies and criteria is reflected in the techniques employed in social planning.

90. Most methods and techniques of social planning depend on an analysis or establishment of requirements. An exception to this, however, is the cost-benefit analysis, the purpose of which is the measurement of the economic benefits of social planning. As the name indicates, cost-benefit analysis attempts to determine what the benefits and costs of a certain project are and to compare these with those of other projects. Although in the case of social sectors one of the most difficult problems is that of measuring the benefits, in a number of cases this has not proved to be impossible and cost-benefit analysis has received increasing attention in the context of social planning.<sup>208</sup> Among the planning techniques relying on requirements is that based on the principle of complementarity. This method is based on the complementarity which exists between many factors in the economic and social fields and focuses on what implications the primary objectives of planning have for other variables which are considered instrumental for the former. It thus determines the targets in one sphere required to meet certain objectives in another sphere of planning. The best-known example of this technique is found in manpower planning, where the labour force according to qualifications and skills required to attain certain levels of output is determined.<sup>209</sup> Both these methods do not, however, establish in a specific manner what should, in general, be the planned levels of the various social variables and sectors. To determine the latter, requirements in development

planning can be approached from the social perspective: instead of establishing targets derived from economic requirements, it is possible to set social targets and to determine what economic resources are required. This method is extensively used in sectoral planning in the social fields.<sup>210</sup>

91. In so far as plans for the social sectors imply the assessment of social needs, a first step is the setting of standards for the individual or group. The fixation of standards involves a number of problems. Among these are the questions of what standards should be selected—in the case of education, for instance, literacy, compulsory primary school attendance etc.—what levels should be set, and over what period they should be reached. Various criteria can be used as far as the last problem is concerned. Some minimum level of social advance is necessary as a prerequisite to economic growth, but there is no absolute criterion what this level should be. Apart from setting standards in a relatively arbitrary manner, one method is to derive standards from a comparative analysis of development patterns within the total context of economic and social development. An alternative method is to derive standards from the practices of other countries presently at the same or a similar level of development or from the past experience of presently more developed countries.<sup>211</sup>

92. Demographic considerations are relevant in planning for the social sectors in so far as plans for these sectors aim directly at fulfilling specific needs of the population and much of the demand for these services is intimately related to population and demographic considerations. As far as the sectors here considered are concerned, educational needs vary with age and are concentrated, except for adult education or literacy campaigns, mostly in what are referred to as the school-going ages. Future educational needs will depend a great deal on the absolute increase and relative importance of the population in these ages, taking into account also the needs for education of different types and levels within this group. In health planning, mortality is itself one of the main components and, in addition, health provisions must reckon with such factors as sex, age, fertility and area of residence as well as over-all population trends. Likewise, housing needs must be formulated mainly on the basis of the family unit, the size, composition and growth of which is, in turn, to a great extent determined by such demographic factors as fertility and mortality, sex-age composition, and population growth. Together with the standards adopted, these demographic factors will determine the planning targets. Once standards in terms of the population or its functional age-groups have been set, the needs of the whole society can be derived

<sup>206</sup> However, it has also been pointed out that the possible conflicts between social and economic considerations in development programmes exist only in the short run and that in the long run the objectives of both economic and social programmes are identical. United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963) and ———, *Problems of Social Development Planning* ... (1964), p. 67.

<sup>207</sup> United Nations, *Report on the World Social Situation* ... (1961), p. 38; United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963).

<sup>208</sup> United Nations, Economic Commission for Africa, "Some problems of social development planning ..." (1962); United Nations, Economic Commission for Asia and the Far East, *Problems of Social Development Planning* ... (1964), p. 65; Tinbergen, "Social aspects ..." (1965). See also especially United Nations Research Institute for Social Development, *Cost-Benefit Analysis of Social Projects* ... (1966). Closely related to cost-benefit analysis is the comparative cost analysis which, estimating the cost involved in a given project, compares it with the present or future cost of not dealing with the problem under consideration.

<sup>210</sup> United Nations, *Report on the World Social Situation* ... (1961), p. 36; United Nations, Economic Commission for Africa, "Some problems of social development planning ..." (1962); United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963).

<sup>211</sup> United Nations, *Report on the World Social Situation* ... (1961); United Nations, Economic Commission for Africa, "Some problems of social development planning ..." (1962); United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963).

from the expected future population growth and trends in its composition. Having calculated the global amount of services needed, the requirements in terms of resources needed can be compared with the available resources.

93. Population projections as an element in determining the future needs play an important role in the planning of these sectors. Estimates of future total population and its different contingents are fundamental requirements as a basis for planning in these sectors. In addition, even outside the specific context of target-setting, demographic projections deserve special attention in setting and determining the goals of development. In this connexion, projections may be used to determine what, given different goals, the over-all implications for planning are and the result, especially if implying an undesirable state of affairs in the future, can become in itself a major factor influencing policy decisions. Likewise, alternative projections can serve the same purpose as guides for determining objectives and targets.<sup>212</sup>

#### 1. EDUCATIONAL PLANNING AND DEMOGRAPHIC CONSIDERATIONS

94. Educational planning has come to be increasingly recognized as of fundamental importance in planning for development and growth. In this connexion two major aspects of an approach to educational planning are usually distinguished. The first is based on the premise that a certain level and content of education provide the individual the opportunity to develop his potentialities to the highest possible degree, by itself one of the main objectives of development and social well-being. Education, however, also constitutes an essential pre-condition for economic growth as far as the latter is a function of not only material but also of human resources. Through the improvements in skills, knowledge and training as well as by developing attitudes conducive to economic change and progress, education plays an important and, according to many, even a crucial role in economic development.<sup>213</sup> Traditionally, education has been considered mainly as a form of social consumption and it is

only in recent decades that the approach to education as investment in human resources has emerged and become widely accepted. The recognition that economic progress depends to a large extent on the development of human skills and training has not only had a profound effect on educational planning, but has also brought about large changes in planning for social and economic development in general. One of these changes has been the progressive integration of educational programmes into the whole planning process.<sup>214</sup>

95. Among the basic issues concerning educational programmes in integrated planning is the problem of the priority of educational as compared with other economic and social planning objectives and that of priorities within the educational plans themselves. With the increased emphasis on education as a factor in economic and social development in general, the traditional view that expenditures on economic development should take precedence over those in social services, including education, has weakened. However, there are a large number of competing needs which lay a claim upon limited resources besides education and since education absorbs an important part of public and private resources, the problem of allocation of resources between education and these other development needs has become prominent.<sup>215</sup> No clear criteria exist, either, for determining priorities within educational plans themselves. Among the issues involved in this decision-making process is the choice between more or less emphasis on different types and levels of education, between a larger quantity or higher quality of education, between satisfying the needs for education of one group or segment of the population or another, and so forth. Whereas decisions on such questions vary from country to country, the predominant view is that in the allocation of the resources for education, high priority should be given to the education and formation of trained and skilled personnel.<sup>216</sup>

96. As far as educational planning itself is concerned, a number of different approaches exist. With certain variations the following categories are often distinguished. The "social method" of educational planning is based on educational needs in terms of the current demand for education at different levels and involves the projection

<sup>212</sup> United Nations, Economic Commission for Africa, "Some problems of social development planning ..." (1962). The population projections needed for planning the different sectors have been discussed in detail in chapter XV, section D.

<sup>213</sup> United Nations, *The United Nations Development Decade* ... (1962), p. 7; United Nations Educational, Scientific and Cultural Organization, *Conference of African States* ... (1967); Parnes, "Manpower analysis in educational planning" (1964); Vaizey, *The Economics of Education* (1962); Harbison and Myers, *Education, Manpower and Economic Growth* ... (1964). In addition to these and other factors, the role of education in reducing levels of fertility and population growth in developing countries and the consequent improved outlook for economic and social development under these conditions have been stressed by several authors. See, for instance, United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963); Vaizey, "Demographic considerations ..." (1967).

<sup>214</sup> United Nations Educational, Scientific and Cultural Organization, *Conference of African States* ... (undated), pp. 9 ff.; ———, *Meeting of Ministers of Education* ... (1962), p. 8; Phillips, "Economic and social aspects ..." (1962); Schultz, "Investment in man ..." (1959); Sauvy, *La montée des jeunes* (1959), pp. 104-105.

<sup>216</sup> Phillips, "Education and development" (1964); Lewis, "Education and economic development" (undated); Harbison, "The process of educational planning" (undated) and his "Human resources and development" (1964); Anderson and Bowman, "Theoretical considerations ..." (1967).

of these needs in function of the population increase, its age-distribution, long-term national goals and so forth. The "aggregate method" attempts to relate educational needs to some criterion of the society's demand for education based on norms or patterns found in other countries. The "education-output ratio" method, comparable to the capital-output ratio approach in economic planning, relates the stock of educated people and the changes in education at different levels directly to national output and its increase. The "manpower approach" is founded on the links between education and economic growth which exist through the knowledge and skills of the labour force. Finally, the "human resources approach" attempts to integrate education with other factors in human resources formation—such as measures in the field of manpower, employment, training and health—into development planning.<sup>217</sup>

97. These different approaches to educational planning have in practice led to a great variety of educational programmes depending on which factor was considered to be of most importance. Despite this lack of uniformity, attempts have been made to determine the aspects to be covered in comprehensive national planning. Phillips lists the following steps: projection of the future size and demographic composition of the population by single years up to 24 years and for a period of 15 to 20 years; the setting of a social standard or social minimum of education and a target date for attaining it; the study of long-term plans or projections of the economy by sectors and subsectors; the determination on the basis of these projections of the requirements for manpower and its desired occupational structure; the translation of occupational requirements into educational components; the review of targets based on social standards or occupational demand in order to take into account such factors as switches and turnover during schooling; geographical adjustment; effects of the increased supply of education on the demand for it; the need for formal education not considered in the preceding steps; requirements of adult education; and literacy campaigns. Subsequently the quantitative and qualitative changes required in the educational system and process and its implications for teacher training, school construction and so forth have to be determined. Once the total cost of these and other provisions has been established, planners have to be confronted with the available resources and the educational requirements arrived at have to be adjusted to fit into the over-all plan. Finally, according to Phillips, studies of incentives required for guiding

students into particular studies and school-leavers into occupations as required by the demand for labour should form part of the planning process.<sup>218</sup>

98. While practices may differ, educational planning, it is held, should for several reasons be preferably medium or long-term planning. First, the educational process itself extends over a long period and for its planning to be co-ordinated at the different levels, a long-term time perspective is necessary. Secondly, changes in the educational system may in many instances take a considerable period; in particular, the training of teachers may often take a number of years and, therefore, should be planned well ahead. Finally, it has been argued that investments in education are often "lumpy" and for that reason do not lend themselves easily to short-term planning.<sup>219</sup>

99. Population composition affects educational needs and capacity and, therefore, planning for education in a number of ways. The higher the fertility, at given levels of mortality, the larger is the population of school age relative to the total population and that of working age. Thus for stated standards of schooling, educational systems are proportionately more expensive in countries with high fertility than in those with low fertility, not only because the proportion of those in need of education is higher, but also since the working population, which has to support the former, will tend to be relatively smaller.<sup>220</sup> Raising the levels of education may have the additional effect of reducing or eliminating the participation of the school-age population in economic life, thus increasing the cost of education while limiting the capacity to pay for it.<sup>221</sup> Finally, a young age structure implies with equal pupil-teacher ratios and equal educational attainment the need for a larger number of teachers per thousand population than in the case of an old-age composition.<sup>222</sup> Apart from the age structure, the population's sex distribution occupies an important role in educational planning because of the often large differentials in school attendance and levels of education of each of the sexes. In many developing countries the proportions of boys and girls attending all levels of schooling differ substantially and even in many developed countries female enrolment, especially at higher levels of education, remains considerably below that for males.<sup>223</sup> The need for eliminating such inequities, where they exist, requires the considera-

<sup>218</sup> Phillips, "Education and development" (1964) and his "Economic and social aspects ..." (1962).

tion of the sex distribution in formulating educational plans.<sup>224</sup>

100. The rate of population growth may have both direct and indirect implications for educational planning. High growth of population, and of the school-age population in particular, causes a rapid expansion of educational requirements. To the extent that high rates of population increase are associated with a young age distribution providing for education of the school-age population places a heavy burden on resources. The combination of high fertility, low or declining mortality and rapid population growth in many developing countries, it has been noted, constitutes, both through the age distribution effect and the rate of growth of the school-age population, a limiting factor in setting educational targets.<sup>225</sup> Variations in the rate of population growth, especially those which result in "bulges" in the age distribution, may also present considerable problems where educational planning is concerned. Especially in the case of compulsory primary education, such effect may be important, it is asserted, because teachers' training frequently starts even before the birth of the children they have to teach. Post-primary education would be less affected since a longer period would be available for it to adapt itself to such population surges and at these levels enrolment rates and not the number of potential students are the main determinants of needs. The latter argument would also hold where primary education is not compulsory or is less than complete.<sup>226</sup>

101. The geographical distribution and settlement of population have an important bearing. Differences in density, the degree of concentration and patterns of settlement of the population have considerable effects on educational attainment.<sup>227</sup> These differences may be partly due to the impact of the economic, social and cultural environment on schooling, as exemplified in the case of urban and rural areas. Rural schools are often handicapped because of inadequate facilities, poor staffing and insufficient equipment and materials as well as by the lack of incentives for education on the part of the population. On the other hand, density and settlement by themselves may be a direct factor in formulating objectives for education. A low density of population and its spread over large areas may, because of the costs involved, often seriously restrict the planned expansion of education in such areas.<sup>228</sup>

102. Demographic factors play a major part in the process of educational planning itself. Especially for

<sup>224</sup> United Nations, *Asia and the Far East Seminar on Population* ... (1957), pp. 27-28; United Nations Educational, Scientific and Cultural Organization, *An Asian Model* ... (1966), pp. 100 ff.; *Conference of African States* ... (undated), p. 6.

planning, education in general population growth and structure are fundamental. The starting point is as a rule the preparation of projections of the future size and demographic composition of the population and of the population in school-going ages, up to 24 years, by single years for a period of 15 to 20 years. On the basis of these latter projections and targets, determined by a social standard or minimum, to be reached at a certain date, future educational requirements are established. Since targets are as a rule set for the different levels of education, these projections, taking into account expected wastage and drop-outs, provide pyramids of educational expansion at different times during the planning period. The educational pyramids are in turn the point of departure for formulating specific programmes within the educational plans such as those for the training of teachers for different educational levels, for the construction of school buildings during the different phases of the plan and so forth. The general picture of educational development thus obtained can then be evaluated in terms of cost and capacities and, where necessary, modified to allow for insufficient resources, bottle-necks in certain programmes etc.<sup>229</sup>

103. Whereas demographic projections thus are an integral part of educational planning, their direct influence on the scope of educational plans depends on the nature of the plans. Where programmes of compulsory education exist and are actually implemented, the problem of estimating needs and setting targets is uniquely demographic and determined by the number and distribution of the population of school-going age. If the entire school-age population does not receive education, as is usually the case for all levels of education in the developing countries and for secondary and higher education in the more developed countries, both demographic factors and social and economic criteria on which standards for education are based will determine the expansion of education.<sup>230</sup>

104. The relevance of demographic factors for manpower planning is more indirect since, involving the formulation of future manpower requirements for economic development, economic considerations play an important role. No generally accepted methodology for the planning of manpower exists, but one approach frequently found consists of the determination of the manpower requirements in terms of different occupations in accordance with the long-term economic projections. These requirements, established on the basis of surveys, past trends or changes in productivity, are then translated into their educational components. The resulting projections of the educational demand have to be compared with the projected supply as based on the projections of the size and growth of population and existing or desired trends in rates of school enrolment and attendance. After the necessary adjustments, the quantitative changes required to meet the estimated demand at the different educational levels can then be assessed.<sup>231</sup>

(Continued on next page)

105. Unlike in most other spheres of planning an international, regional approach to educational policies and development has emerged and regional policy statements and goals for educational development have been formulated for the world's major regions. Regional targets calling for universal primary education and sharp increases in secondary and higher education by the target dates were set by the ministers of education of Asia, Africa and Latin America, and these targets were widely accepted by individual nations. The "Karachi plan" for Asian countries called for free and compulsory education of at least seven years' duration for all children by 1980<sup>232</sup> and was subsequently extended to include, even though no specific targets were set, the expansion of secondary and higher, as well as adult education.<sup>233</sup> For this purpose of long-term educational planning in the region, a model for educational development was formulated which attempted to establish in quantitative terms the prospects of educational development and at the same time illustrated the interrelationships between the main factors involved in educational planning and between educational and other variables.<sup>234</sup> The plan for African educational development also set universal, compulsory and free primary education as a target for 1980, but stressed that secondary and higher education would be expanded to include, respectively, 23 and 2 per cent of the population in the appropriate age groups.<sup>235</sup> The Conference on Education and Economic and Social Development in Latin America recommended that efforts be made to attain universal, six-year primary education by 1970 and to expand secondary and develop higher education.<sup>236</sup> Targets for education in 1970 were also prepared for eighteen countries in the Organisation for Economic Co-operation and Development (OECD) region<sup>237</sup> and for six countries in a Mediterranean regional project.<sup>238</sup>

106. Demographic considerations have appeared in both the regional and the national plans for education. The recommendations for action at the national level by member States participating in the "Karachi plan" stressed the need for demographic statistics, studies and projections.<sup>239</sup> The need for an adequate demographic

base for planning was also stressed at the meeting of the ministers of education of the countries participating in the "Karachi plan". In Burma, the lack of reliable population data by age was seen as an obstacle to planning and in the case of Afghanistan it was noted that the target data had to be advanced to 1990 because of the fact that the original population estimate for the country was one fifth below the actual population.<sup>240</sup> The working plan of the "Karachi plan" emphasized the rapid increase of the population in the region, noted the importance of the high rate of growth of the school-age population as one of the main factors in the very large increase in primary school enrolment—171 millions or 258 per cent—needed to attain the target for 1980 and also pointed in this connexion to the rapid increase of enrolment in successive quinquennia of the plan period.<sup>241</sup> The demographic conditions and trends—especially the high levels of fertility, the rapid growth of population, the high dependency rate, and the rapid process of urbanization—were considered as having serious implications for educational planning in the region,<sup>242</sup> a viewpoint which was also reflected in the national plans of various countries.<sup>243</sup> A study aimed at determining the importance of population growth for the target of universal primary education in India, Indonesia, Pakistan and the Philippines, revealed that the rate of increase in population was an important factor in all cases, and accounted for the largest share of needed future enrolment in Indonesia and the Philippines, where current levels were already high.<sup>244</sup>

107. In African countries the lack of demographic data in sufficient quantity and of satisfactory quality constitutes a serious obstacle to planning in general and to educational planning in particular.<sup>245</sup> Even so, a number of African countries have made efforts to utilize the limited available demographic information in their educational plans; projections of school-age population were included in the plans of Madagascar,<sup>246</sup> Gabon<sup>247</sup> and Zambia<sup>248</sup> and estimates of enrolment rates were prepared for the Ten-Year Plan of the Sudan.<sup>249</sup> Rapid population growth and the high proportion of population

in younger ages, both associated with high fertility, are, together with economic constraints, among the factors which affected educational planning unfavourably in various countries. In Ghana's Seven-Year Development Plan, where the development of education was linked to employment, it was found that even though employment in the modern sector in the past had increased considerably, the expansion had fallen far short of even absorbing the total output of elementary schools in the same period.<sup>250</sup> Rapid population growth was also seen as a serious obstacle to educational targets. Estimating the cost of providing educational facilities on the basis of alternative population projections, the plan stated that if the objective of universal primary education were to be attained in a reasonable period without seriously jeopardizing economic growth, the rapid increase of population would have to be checked.<sup>251</sup>

108. The Conference on Education and Economic and Social Development in Latin America noted also the need for more adequate educational and demographic data for planning education. It also observed that rapid population growth intensified the problems of educational progress found in the region.<sup>252</sup> In the Conference of Ministers of Education and Ministers responsible for Economic Planning in the Countries of Latin America and the Caribbean, it was reported that even though the rate of expansion at all levels of the educational pyramid had been more rapid than the growth of population in the corresponding age groups, serious problems persisted at the primary level and the secondary and higher levels were still unable to absorb sufficient numbers to satisfy the demands of society. Various countries noted the problems created by high population growth in extending education, the unlikelihood of attaining the goals set for 1970 because of the pressure on available resources, the need to adapt teacher-training programmes so as to be able to satisfy the basic demand for education, and so forth.<sup>253</sup> In more general terms, it has been stated that the rapid growth of population and of the number of children of ages 5 to 14 years as well as the accelerating rate of urbanization are among the factors which complicate educational planning in the region.<sup>254</sup> The implications of demographic factors for planning education were discussed in a number of development plans of Latin American countries. In the general development plan of Colombia, population growth trends were analysed in detail and their consequences for the expansion of basic education were examined. The plan noted the rapid growth of the population in school-going ages as well as the increase of the proportion of the population under 15 years in urban areas owing to heavy internal

migration.<sup>255</sup> The demographic pressure caused by the rapid growth of population was analysed in the development plan of El Salvador, which gave special attention to the planning of education in relation to the development of manpower resources. Demographic projections were used as a basis for estimating school enrolment in general and for analysing employment goals and manpower needs.<sup>256</sup> Other plans also took into account demographic factors in planning for education. In the case of Bolivia, where the problem of illiteracy was thought to merit special attention, especially as far as rural areas were concerned, projections of urban and rural school-age population were used to show the magnitude of the problem of spreading basic education and eliminating illiteracy.<sup>257</sup> In countries such as Venezuela<sup>258</sup> and Uruguay,<sup>259</sup> demographic considerations in educational planning dealt mainly with problems of creating employment opportunities for an expanding labour force.

109. Educational planning in the more developed countries presents different problems than in the developing, also in so far as demographic factors are concerned. In a report on the nature and magnitude of the task of education in the countries forming part of the Organisation for Economic Co-operation and Development, it was noted that, together with economic and social needs, demographic factors would be an important factor in the future expansion of education. The growth of population as it affects the corresponding school-age population would be the major factor in the increase of primary education, but would also be reflected in the growth of secondary and higher education where the expansion of the educational system would be concentrated.<sup>260</sup> Large changes in the school-age population have had special relevance in the planning of education in France, where yearly age groups of less than 600,000 children in 1946 have progressively increased to 800,000 or more. This "demographic wave", caused by the post-war increase in births, reached primary schools in 1952, secondary schools in 1957 and started to intensify the demand for higher education in the early 1960s. Combined with increasing enrolment ratios at the secondary and higher levels, it led to the need for an exceptionally rapid expansion of education in those years.<sup>261</sup> The extent to which demo-

graphic factors enter into planning for higher education can be illustrated by the case of the United Kingdom of Great Britain and Northern Ireland. Taking as a point of departure the demand for higher education from qualified applicants, rather than future manpower requirements, the need for places in higher education is determined by the size of the age group relevant to higher education, the proportion of the age group obtaining the necessary qualifications and the proportion of those qualified who apply.<sup>262</sup>

110. In the centrally planned economies of Eastern Europe, educational planning is considered a basic aspect of economic progress and cultural development and an integral part of over-all planning. In the Soviet Union, where eight-year schooling is compulsory, plans for expanding the educational system up to that level were based first and foremost on population growth. On the basis of analysis of demographic trends, estimates of the corresponding population by age groups were made, thus establishing the number of pre-school and school-age children as a basic requirement for planning universal compulsory primary education. With the efforts to complete the transition to universal compulsory secondary education and the continued rapid increase of higher education, determined by the needs for highly qualified manpower, plans foresee large increases in the educational system at these levels.<sup>263</sup> The effect of the increased number of children born in the post-war period also affected educational planning in several of the socialist countries. The Five-Year Plan (1956-1960) of Poland foresaw a large increase in the construction of primary schools in order to absorb the very large number of children reaching school-age during the period.<sup>264</sup>

## 2. HEALTH PLANNING AND DEMOGRAPHIC CONSIDERATIONS

111. In general terms, health planning may be said to be concerned with and include all the services, including environmental ones, for promoting and maintaining communal and individual health.<sup>265</sup> As in others of the so-called social sectors, the health planning has two aspects: good health is by itself an objective of development, but, in addition, disease, inadequate health and insufficient sanitation are obstacles to attaining rapid development. Health planning, it is argued, must thus be an integral aspect of economic and social planning.<sup>266</sup>

<sup>265</sup> World Health Organization, *Basic Documents* . . . (1969), p. 1, defines health as "... a state of complete physical, mental and social well-being". See also Winslow, *The Evolution and Significance of the Modern Public Health Campaign* (1923), p. 1; World Health Organization, *Planning of Public Health Services* (1961), pp. 4-5.

<sup>266</sup> United Nations, *The United Nations Development Decade* . . . (1962), pp. 64-65; World Health Organization, *National Health Planning in Developing Countries* (1967), pp. 12, 21-22; United Nations, *1967 Report on the World Social Situation* (1969), p. 31; United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963).

112. The relations between health planning and planning in general are, in turn, mutual. Increases in income and levels of living of the population are bound to affect the demand for health services and the resources which would become available for health provision. At the same time, apart from its general impact on individual and social well-being, the importance of good health and planning for economic development has been emphasized. Health programmes, it is argued, will contribute substantially to raising the quality and productive capacity of the labour force—through better health of the workers in general, a higher degree of fitness, less absenteeism due to sickness as well as through improved environmental sanitation—thereby helping to raise national income and well-being more rapidly.<sup>267</sup>

113. Although it has been asserted that because of its effects on economic growth, outlays on health services should be regarded by the planning authorities as on a par with investment in capital,<sup>268</sup> it has also been pointed out that health plans make large demands upon a country's investment funds, especially where hospitals, medical and other training schools and environmental sanitation are concerned. Especially in the developing countries where resources are small and needs great, health plans will have to compete with the country's requirements in other fields.<sup>269</sup> Since health provisions cover a wide range of services and activities and resources are limited, the establishment of priorities and the setting of targets become difficult tasks. In general, health planning, involving the selection and determination of those forms of health activities best suited to the health needs of the community, has as its usual starting point the assessment of the existing health status of the population and its needs for all types of health services.<sup>270</sup> On this basis the priorities, given the available resources, are formulated. According to a report prepared for the World Health Organization, the priorities or criteria in the field of health planning might include: emphasis on prevention; services to people engaged in productive work;

<sup>267</sup> World Health Organization, *Planning of Public Health Services* (1961), p. 8; United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963); Taylor, "Health and Population" (1967); Taylor and Hall, "Health, population and economic development" (1969); United Nations, *Report on the World Social Situation* (1961), p. 33 which also noted however, that the effect of health programmes on labour productivity might be insignificant if there exists already a pressure of population on resources and a labour surplus. In more general terms, it has also been recognized that not all health services contribute to economic growth and that the assessment of health planning in this respect is difficult. World Health Organization, *National Health Planning in Developing Countries* (1967), p. 22; United Nations, *Report on the World Social Situation* (1961), p. 33.

<sup>268</sup> World Health Organization, *Planning of Public Health Services* (1961), p. 8, however, also notes that the contribution of health plans may be less direct than that of productive capital. See on this latter point also United Nations, *Report on the World Social Situation* (1961), p. 33.

<sup>269</sup> World Health Organization, *National Health Planning in Developing Countries* (1967), pp. 22 ff.; United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963); Rivkin, *The African Presence in World Affairs* . . . (1963), p. 118.

<sup>270</sup> World Health Organization, *Planning of Public Health Services* (1961), pp. 11-12; Biraud, "Implications of population trends . . ." (1964).

services to vulnerable groups (such as mothers and children); services which would affect the health of the largest number of persons and improvements of the nutritional standards of the population.<sup>271</sup>

114. Once these priorities have been determined as objectives and targets, specific health provisions can be formulated. These cover a wide range and include in general the following categories: services for environmental improvements; personal and social health services for the healthy, the handicapped and the sick; the control of communicable diseases and general services; education of personnel and research and other services which contribute to health, such as good nutrition, labour standards and so forth.<sup>272</sup> From these targets the implications for different categories of health services and the allocation of the available resources are derived, including such aspects as the number of hospital beds, doctors, health workers; the construction of new hospitals and other capital investments; the cost of maintaining the services etc.<sup>273</sup>

115. The time period over which health plans are drawn up varies considerably. To the extent that many elements of health plans, such as the training of medical personnel, the construction of hospitals and health centres require a long time, the plans may extend over as much as ten or twenty years.<sup>274</sup> However, such perspective plans often provide no more than a general picture of possible development. The possibility of unpredictable discoveries in medical knowledge, the uncertainty as to how far existing knowledge will be used and will contribute to health progress, the impossibility of foreseeing changes in economic and social conditions which affect health, all suggest the limitations inherent in such perspective plans and the desirability of preparing, in addition, plans over shorter periods from one to five years.<sup>275</sup>

116. Demographic considerations are of particular relevance in health planning in so far as data on mortality, morbidity, fertility and so forth provide the basic information on health conditions, requirements and priorities. As indicators of health conditions, demographic data are indispensable in assessing the health situation at the time of plan formulation and for the evaluation of progress

in the implementation of plans.<sup>276</sup> The demographic data which, together with other information, is required for health planning include particularly different measures of mortality—such as crude death rates, sex-age specific mortality rates, infant mortality and related measures, expectation of life, causes of death—as among the major indicators of health conditions. This information, in conjunction with other demographic data on fertility, the sex-age composition and the geographic distribution of the population, fundamental for health planning, is especially in developing countries often lacking or incomplete. For health planning the need to develop the statistical organizations which collect this information and to ensure adequate vital and health statistics which would provide a continuing and reliable basis for planning is, as has been frequently noted, essential.<sup>277</sup>

117. The levels of mortality and the age-specific death rates associated with them are not only indicators of the existing health conditions, but may also be important as factors determining the priorities within health programmes. A close relation exists between health needs and age, due to different general health conditions of the individual and the changing incidence of certain diseases at different ages. Priorities and targets in health planning are consequently often formulated with respect to population segments whose characteristics are closely associated with age, such as infants and children, pregnant women and mothers with young children, workers, aged persons and so forth. The age distribution thus becomes an important consideration in formulating priorities and, once the latter and the specific objectives have been established, in determining the total needs and the scope of programmes.<sup>278</sup> Differences in health planning and priorities between developed and developing countries, while responding primarily to the differences in mortality and morbidity characteristics of these countries, may be further increased by the implications of the different age composition for total health needs.<sup>279</sup>

118. Future health needs are a function of the different requirements resulting from the changing importance of

On the different economic impacts of health provisions for persons in different ages, such as, for instance, a young person about to enter into the labour force and a retired worker, see Singer, *International Development* ... (1964), pp. 73 ff.; United Nations, Economic Commission for Latin America, "Social development" and "social planning" ... (1966); United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963).

<sup>279</sup> On the need for emphasis on health problems of infancy, childhood and early adult life in the young populations in developing countries see, for instance, Puffer, "Growth of population and public health programmes ..." (1958); United Nations, *Asia and the Far East Seminar on Population* (1957), p. 26.

different diseases and other health problems and of the changes in population.<sup>280</sup> Future population growth and sex and age composition and the expected future trends of fertility and mortality together with the changing health needs themselves are at the basis of future requirements in the field of health. Population projections and its changing composition are thus important factors in determining the scope of future health programmes.<sup>281</sup>

119. The geographical distribution of the population and its patterns of settlement are thought to have various implications for planning in the field of population. The degree of concentration or dispersion of population will not only be associated with different problems in health planning, but will also have repercussions for the programming of services.<sup>282</sup> The high density and concentration of population in urban areas requires, for instance, a much higher priority on environmental health than in rural areas, but provides more opportunities for specialization of health services than in the latter. Rapid urbanization in many developing countries, however, often poses, a considerable strain on health conditions and planning. Rural areas, in turn, are faced with other problems. Where density is low, the population scattered and communications inadequate, the health needs can only be satisfied at a substantial cost. Density and settlement patterns will also influence the distribution of health units and services, in particular the choice between smaller health units and more limited services—such as dispensaries—in more localities or larger units providing a wider range of health care—such as hospitals—concentrated in a few larger places.<sup>283</sup>

### 3. PLANNING FOR HOUSING AND DEMOGRAPHIC CONSIDERATIONS

120. Housing and food are among the primary needs of man and securing adequate and sufficient housing is one of the most deeply felt social needs. However, the viewpoint that the provision of housing is not only an objective by itself, but that it may have direct relevance to development has gained wide acceptance. Housing construction, it is argued, creates substantial employment, raises the efficiency of other investment, and increases

the productivity of labour through the effects improved housing conditions have on morbidity and health, labour stability and so forth.<sup>284</sup> Housing policies and objectives, it is concluded, should therefore be placed in the broader context of over-all planning and planning for housing should be co-ordinated with general economic and social planning and be given a suitable priority.<sup>285</sup>

121. As in the case of other sectors, and particularly the so-called social sectors, no completely satisfactory criteria for the allocation of resources to housing exist. In practice, housing has frequently been assigned a relatively low priority in planning social and economic development, the reasoning behind this being that residential construction involves heavy investment outlays but tends to have a low return, that is, a high capital-output ratio. This factor weighs heavily in developing countries where capital resources are already limited.<sup>286</sup>

122. In general, the long-term objective of housing is to ensure decent housing complying with certain minimum standards for the mass of the population.<sup>287</sup> Whereas one of the main tasks in planning for housing needs is the determination of total requirements, a comprehensive housing programme will also have to take into account the prospective future changes in the distribution of housing needs by size, number of rooms and so forth.<sup>288</sup> Housing programmes will also have to estimate or determine the existing shortages in housing, both in quantitative and qualitative terms, as indicated by such factors as over-crowding, doubling-up of households, the use of inadequate or substandard housing units, waiting lists of applicants for housing and so forth. Finally, in determining housing needs, allowance must be made for the deterioration of the existing stock of housing and the

In addition, it has been pointed out that one of the goals of economic development policy itself should be the improvement of efficiency in the building industry. United Nations, *Report of the Ad Hoc Group of Experts on Housing and Urban Development* (1963), pp. 5-6, 26 ff.

<sup>286</sup> United Nations, *Report of the Ad Hoc Group of Experts on Housing and Urban Development* (1962), pp. 12, 18; —, *Report of the Interregional Seminar on Rural Housing* ... (1968), pp. 67, 76-78.

<sup>287</sup> United Nations, Economic Commission for Asia and the Far East, *Problems of Social Development Planning* ... (1964), p. 35. More specifically it has been argued, however, that the objectives of housing programmes should be realistic. See United Nations, *Methods for Establishing Targets* ... (1968), pp. 12 ff.; United Nations, Economic Commission for Asia and the Far East, "Social development planning" (1963).

<sup>288</sup> United Nations, "Implications of population trends ..." (1964).

replacement demand, including the upgrading of existing levels of accommodation.<sup>289</sup>

123. As distinguished from housing needs, the potential supply of housing is determined by the available resources and the effective demand by the levels and distribution of income and the cost of housing. After evaluating the needs, resources, demand factors and other constraints, the housing programmes, it is asserted, should be so framed as to utilize the available resources most effectively and in such a manner that the more urgent and vital needs are satisfied.<sup>290</sup> Although plans so formulated can be reviewed and may need alterations because of unforeseen developments, medium- and long-term programmes are most usual in the case of housing.

124. Demographic aspects are acknowledged as a major determinant of housing policies and programmes. The demographic composition of the population is the basis for assessing housing needs in so far as the size and composition of the household, as the basic unit in housing programmes depends to a large extent on the sex, age and marital status composition of the population. Apart from those of unmarried persons living by themselves, new housing needs normally arise at the time of marriage. The required size of the dwelling increases with the birth and growth of the children and later decreases when the children leave home and the marriage is dissolved through the death of one of the spouses. Nuptiality, age at marriage and the levels of fertility and mortality are thus bound to have an important effect on housing needs.<sup>291</sup>

125. Besides the replacement of deteriorated dwellings and the reduction or elimination of existing housing shortages and deficits, population growth is the third and often the most important element in determining over-all housing needs. Population changes affect housing needs primarily through changes in the number of families which normally share one dwelling and the higher the rate of population growth the faster will be the rate at which housing needs increase. In general, housing needs may increase proportionately with the growth of population if the size and composition of the family or basic household unit remain unchanged. Changes in population and housing needs may no longer be proportionate where population growth slows down or accelerates since such a process is frequently associated with changes in the population composition and structure which involve corresponding modifications in the size and structure of households. It is thus not only the level of population growth, but its components and their behaviour which

determine the demographic implications for housing needs.<sup>292</sup>

126. The geographical distribution of the population and especially its urban-rural composition and changes in it have a considerable impact on planning for the housing sector. In view of the different standards and requirements for housing in urban and rural areas, the volume and types of housing needs may vary considerably with the relative levels of urbanization, the more so because of differences in the demographic composition of the urban and rural population. Moreover, the housing sector in urban areas is so closely related to other aspects of urban environment—such as transportation from home to work, sanitary services and other public utilities—that co-ordination between housing programmes and planning for other urban facilities is imperative.<sup>293</sup> The inflow of population into the cities in many developing countries in particular signifies a rapidly increasing need for housing and related utilities which in many cases, because of the scarcity of available resources, poses serious problems for urban housing programmes. Migration and especially rural-to-urban migration has thus come to be considered as a fundamental factor in planning for housing.<sup>294</sup>

#### D. Demographic considerations in regional planning

127. The term regional planning has been interpreted in a number of different ways and, in so far as it relates to regions within a country,<sup>295</sup> can be defined only in very general terms as dealing with policies for a region or regions, either independently or as part of a comprehensive national plan.<sup>296</sup> Because of the diversity of forms which have in common only their concern with certain spatial aspects of the community or society, it is impracticable to describe in a succinct manner the scope and content of regional planning.

128. Regional planning, it has been said, has evolved basically out of two approaches to spatial problems. The first, according to this interpretation, emerged as part of

<sup>293</sup> United Nations, *Report of the Ad Hoc Group of Experts on Housing and Urban Development* (1962), pp. 1, 9, 17-18. On the question of priority of urban as compared with rural housing, see United Nations, *Report of the Interregional Seminar on Rural Housing* ... (1968), pp. 72-74.

<sup>294</sup> United Nations, *Report of the Ad Hoc Group of Experts on Housing and Urban Development* (1962), pp. 2-3; ———, *Methods for Establishing Targets* ... (1968), p. 27.

<sup>295</sup> The expression regional planning is sometimes also used to refer to the harmonization and co-ordination of national plans, often mainly with respect to the external sector of the economy, of countries in a certain region.

<sup>296</sup> Friedman, "Regional planning ..." (1964) and his *Regional Development Policy* ... (1966), p. 5; United Nations, *Selected Experiences in Regional Development* (1970), p. 7, describes regional development as activities which aim at arranging population and human activities in space and which: (a) have as their main aim the improvement of living conditions among the population at large; (b) reflect a multidimensional approach towards development; and (c) take a region as the essential unit of measure in organizing these activities.

economic policy when, in response to the economic backwardness of a certain region or regions or to excessive regional disparities in levels of living, measures were taken to speed up economic growth in these less advanced areas. The second approach, which became identified with physical planning, was mainly concerned with the organization and development of the physical environment and the rational utilization of space in order to accommodate economic and social activities often within the local community or area.<sup>297</sup> Both of these approaches, however, underwent a gradual transformation. Physical planning advanced, from being confined to planning in determined areas, to encompass various regions or even the whole country.<sup>298</sup> At the same time national economic policies and planning placed increasing emphasis on regional aspects of development and many plans included, besides over-all targets, certain objectives for regional development.<sup>299</sup> With the development of regional aspects in national planning and the evolution of physical planning, differences between the two approaches have narrowed, even though they have not disappeared completely. At present, however, the need for a co-ordinated and integrated approach to regional planning has become widely accepted.<sup>300</sup>

<sup>297</sup> United Nations, Economic Commission for Europe, "Problems of regional economic planning ..." (1966); Rodwin, "Current development in regional planning" (1959); Friedman, "Regional planning ..." (1964).

<sup>298</sup> United Nations, *Regional Planning ...* (1959), p. 2; ———, *International Survey of Programmes ...* (1959), p. 49; United Nations, Economic Commission for Europe, "Problems of regional economic planning and development ..." (1966). Traditionally, it has been noted, physical planning was often limited to the internal arrangements of cities and towns. United Nations, *Regional Planning ...* (1959), p. 2. See also, Glikson, *Regional Planning and Development* (1955), pp. 21-23; Gottmann, "En étudiant la planification régionale" (1952). A recent physical planning oriented classification of planning regions distinguishes: regions of resource development; rural regions in which village improvement projects are carried out; and metropolitan areas. United Nations, *Regional Planning ...* (1959), p. 4; Rodwin, "Current developments in regional planning" (1959). Physical planning at the national level may include country-wide programmes for roads, railways, rivers and electric power networks. On the less than complete integration of these aspects of regional planning in practice see Ginsburg, "The regional concept and planning regions" (1959). On the need to integrate urban and metropolitan planning and national planning see Isard and Reiner, "Regional and national economic planning ..." (1961); Rodwin, "Metropolitan policy for developing areas" (1961). See also Friedman, "Regional planning ..." (1964) who distinguished

129. As the link between the national and local community, the region constitutes a suitable frame for a balanced integration of development projects of national significance and those based on local considerations.<sup>301</sup> In the most general terms, it has been noted, regional planning thus aims at the harmonization of national and local development or, alternatively stated, at comprehensive national development through the progress of different parts of the country. In this sense, regional planning has the dual objective of promoting not only economic growth and social progress in the regions concerned, but also in the country as a whole.<sup>302</sup>

130. Since regional planning in the broad sense used here is linked to national programmes, regional policies and physical and environmental planning, its specific objectives may reflect differences of emphasis on one or the other of these aspects. Regional policies may thus pursue a large number of different objectives which, from the point of view of the individual region, may include: economic and social progress through the development and utilization of the material and human resources of the region; improvement in levels and patterns of location of productive activities and infrastructure investments with a view to environmental factors; the balancing of population with employment opportunities and improved patterns of human settlement; the integration of the region into the natural culture and the creation of better organizational and administrative conditions.<sup>303</sup> From the point of view of national planning for regional development and of interregional considerations, objectives may involve a choice between the development of regions in order to maximize national income and levels of living; the accelerated development of backward regions and depressed areas with a view to equalization; the diversification of regional economies; "balanced" economic growth of regions and so forth.<sup>304</sup> Although in general it is accepted that most objectives of regional planning contribute, directly or indirectly, to attaining higher levels of development and that in many cases they may be identified with the goals of national plans, the different goals are not necessarily consistent. In particular, it has been observed that the maximization of regional develop-

between regional planning and city planning, but stressed the need for integration of the two. See also his "The concept of a planning region ..." (1964).

<sup>301</sup> United Nations, *Regional Planning ...* (1959), p. 7; ———, *International Survey of Programmes ...* (1959), p. 50; ———, "United Nations seminar on housing and community improvement ..." (1955).

ment may be inconsistent with optimum national development.<sup>305</sup>

131. Covering all aspects which affect economic and social development in different areas and localities, the range of measures of regional policy is very broad. In the centrally planned economies, it has been noted, national plans provide for all the main categories of instruments for regional policies. Population and labour force movements are accounted for in the manpower balances; the building-up of the social and economic regional infrastructure is part of the investment plans and so is the location of economic activities in different regions.<sup>306</sup> In market economies, measures for regional development include such diverse aspects as the levels of public expenditures and investment; taxation and subsidies; influencing transportation and transfer cost through direct or indirect control; wage policies and other measures designed to influence the cost of capital; policies designed to affect the mobility of labour and capital and so forth.<sup>307</sup> However, in most of these countries, it has been noted, the effective means for regional development at the disposal of planners are, as a rule, restricted and mainly negative ones.<sup>308</sup>

132. Although the role of demographic factors in regional planning has not been clearly defined, there is a general recognition that the spatial distribution and mobility of the population occupy a central place in the strategy of regional development. The links between these demographic variables and regional development and its planning are close. The level of and outlook for development of a given region is by itself partly a function of the relation between population and material resources and physical environment. In addition, the process of development, whether planned at the national or regional level, will inevitably have implications for the spatial distribution of population, as well as economic activities—the most evident example being that of the urban concentration associated with the industrialization process—which depends to a considerable extent on the mobility of population and resources.<sup>309</sup> Through influencing levels and patterns of migration, regional development policy may bring about a distribution of population and

labour force better adapted to the potential development both of individual regions and the country as a whole. Migrations from backward areas where unemployment and underemployment are widespread to parts of the country where employment is expanding rapidly is an important tool of regional policy in adjusting the supply of labour to the existing or changing regional trends in employment. Even though, as has been observed, employment itself is not necessarily the main objective in regional planning,<sup>310</sup> the improved regional balance of labour supply and demand, through increased over-all employment, will also accelerate economic growth in general and decrease regional differentials.<sup>311</sup> Through measures affecting levels and, especially, patterns of migration, regional policy, by creating alternative employment opportunities and sources of income, may limit the drift of population towards over-developed or congested areas, particularly the large cities, where a greater concentration of population may for a number of economic, social and environmental reasons be undesirable.<sup>312</sup>

133. Nevertheless, the role of migration and changing patterns of population settlement in the strategy of regional development is not without its limitations. As far as policies with regard to backward regions are concerned, one basic question is the choice between migration and other policy alternatives of regional development. Such a choice is influenced by a great number of factors. In general terms, it may be said that where solving the unemployment problems is the primary goal migration policies may be most appropriate. However, if the purpose is to speed up the development of such regions in order to reduce regional income differentials, capital imports may be called for.<sup>313</sup> The choice of strategy also depends to a large extent on the causes of backwardness of the region. It has been argued that where a region remained behind because it failed to adapt its economic structure to change, moving capital to labour will be a more viable solution than in the case of regions handicapped by less favourable resources endowments.<sup>314</sup> The latter is especially true of the over-populated regions where the out-migration of labour may be a major means of adjustment to population pressures and may cause a more rapid economic growth. In the absence of such migration, development might not be feasible or be possible only at the cost of a massive inflow of capital in combination with a large industrialization programme and a radical

<sup>314</sup> United Nations, Economic Commission for Europe, "Problems of regional economic planning and development ..." (1966).

transformation of agriculture.<sup>315</sup> In contrast, migration from regions which are under-populated in terms of resources may prejudice their subsequent development. Capital inflows into these regions would have the double effect of fostering their development and slowing down their rate of out-migration.<sup>316</sup> The volume and characteristics of in-migration become crucial in the case of so-called "new regions" and occupy a central place in their development.<sup>317</sup>

134. In formulating regional development policies, allowance should not only be made for the effects migration has on population size, but also its implications for the age distribution. Because of the age-selectivity of migration, the largest number being concentrated in the ages roughly between 20 to 40 years, these movements tend to decrease the proportion in the labour force in regions of origin and to increase it in the areas of destination. By reducing the relative importance of the most dynamic segment of the labour force, and often the most enterprising and better qualified elements, and by raising the average or median age of the working population, migratory movements might have unfavourable repercussions on economic progress and employment in areas of out-migration.<sup>318</sup>

135. Although levels of living and employment are the most common motivations for labour movements, population, on the whole, will not be completely mobile, nor, for that matter, immobile.<sup>319</sup> Although migration can be induced through such measures as subsidies for education and training, direct financial assistance in moving, provisions for housing and other social services and infrastructure,<sup>320</sup> even strong inducements of this kind, barring direct compulsion, may be insufficient for many unemployed in backward areas to migrate.<sup>321</sup> It has been argued, therefore, that because of these locational preferences, part of the population must be con-

sidered as immobile from the economic point of view. Consequently, it is held, capital development in these regions is primary since, from the economic point of view, it uses labour which must be considered as immobile while, from the social point of view, it satisfies the locational preferences of the inhabitants.<sup>322</sup>

136. As far as the effects of internal migration on the more developed regions and comparative levels of development are concerned, it has been noted that, in general, the mobility of the population increases the income inequality between more and less developed regions. Since migration is selective, both with respect to age and characteristics of the migrants, the more developed regions will attract the most dynamic individuals from the other regions, stimulating the further development of the already more privileged areas.<sup>323</sup> The concentration of population in the large cities especially contributes to such development. Not only does it draw the most qualified labour from rural areas and small towns and cities, but it also absorbs a disproportionate share of the national total and public investment.<sup>324</sup> Urban concentration, it is argued, causes a dualistic structure in the space economy, characterized by a centre of rapid intensive development, equivalent to the modern sector, and a stagnant or only slowly progressing periphery dominated to a large extent by traditional activities.<sup>325</sup>

137. Rapid urban growth creates its own problems and the unprecedented growth of cities in the twentieth century has been said to be one of the most important factors in the development of regional planning.<sup>326</sup> In the great cities where a large population is concentrated, among the main problems are congestion and insufficient transport facilities, lack of public services and social infrastructure, and scarcity of land for housing.<sup>327</sup> Despite the advantages which in principle are derived from geographic concentration, external economies, it has been asserted, increase only slowly, once cities have passed a certain size, while the economic and social disadvantages increase at a very rapid rate, especially where public expenditures and investments are concerned.<sup>328</sup> Particularly in the developing countries, high rates of urbanization, in part the result of high population growth

which contributed pressure to this process directly as well as indirectly through the rural population, have exceeded in many instances by far the capacity of absorption of the cities both in terms of housing and other facilities and employment.<sup>329</sup>

138. Whereas the achievement of improved patterns of urbanization and urban decentralization have been regarded as among the objectives of regional development,<sup>330</sup> urbanization theory, it is held, has not provided the set of principles for such purposes and the assimilation of urbanization policies in the framework of regional or national planning is far from complete.<sup>331</sup> Experience, it has been observed, suggests that the location of new economic activities in such areas and the migration toward these centres cannot be easily controlled. Measures which conceivably might contribute to a greater dispersal of over-developed areas and a reduction of the migratory movements towards them are: the acceleration of economic growth of under-developed areas; the development of satellite and new towns; and the transfer of some of the economic or social activities away from congested areas.<sup>332</sup> Urban and city planning, it is asserted, thus needs to be integrated with planning for the countryside and rural areas.<sup>333</sup> It has been observed, however, that there may exist in this respect a contradiction in rural programmes in so far as they are aimed at holding back out-migration from rural areas, whereas in fact rural development in many instances is conditioned by or may cause rural out-migration.<sup>334</sup> Any policy of regional decentralization, it has been said, to be generally accepted has to consider the concentration of most economic activities in existing or new towns in industrial zones in order to have the benefit of the advantages of location.<sup>335</sup>

139. In general, it is held that a first step in regional planning prior to formulating a programme is the preparation of a comprehensive survey of the region or regions and its problems. Such a study, or "balance sheet", should include: population trends and characteristics; labour force growth, structure and skills; employment and unemployment; the growth of rural and urban population; and actual and potential migration.<sup>336</sup>

It has also been argued that, before defining a regional development policy, demographic and related economic projections should be prepared in order to indicate the possible evolution and to establish the choices of policy objectives and goals to be determined by the decision-makers.<sup>337</sup>

140. Regional planning and policies differ greatly and so does the extent to which demographic factors are taken into account. In the centrally planned economies, regional development is an integral part of planning and the State determining the development goals for each region also sets the economically desirable volume of migration between regions.<sup>338</sup> Active policies for decentralization and dispersal are applied in the Soviet Union and most of the other centrally planned economies, including Czechoslovakia,<sup>339</sup> Hungary,<sup>340</sup> and Poland.<sup>341</sup> Special attention is also given to rural development programmes designed to alter the rural settlement patterns with a view towards increasing agricultural production, such as in the case of Poland.<sup>342</sup> China's first and second plans gave regional development priority through rational geographical location of industries and programmes to build new industrial bases. A balanced regional development was seen as necessary to strengthen national defence and develop backward areas.<sup>343</sup> In this context, it pursued an active policy for controlling the rural-urban migration, including measures for the return of rural migrants.<sup>344</sup>

141. In the developed market economies, regional planning has taken a number of different forms. The best-known example of planning for the development of resources is probably the Tennessee Valley Authority (TVA) which, although primarily responsible for the development of water resources, became a multipurpose project. At least in part as a result of the programme, the region experienced spectacular changes in its economic structure—especially as far as the decrease in agricultural and the increase in manufacturing employment are con-

cerned—a rapid increase in levels of income and a steady growth of population.<sup>345</sup> Regional planning has also received much attention in Italy in connexion with the development of southern Italy. As part of the ten-year plan for 1955-1964, which had among its targets fuller employment and a better balanced and harmonious development of the different regions, investment programmes which would provide productive employment for the unemployed and underemployed and the increase in the labour force in the southern regions were stressed.<sup>346</sup> Regional planning received special emphasis in the Fourth Plan (1962-1965) and Fifth Plan (1966-1970) of France. The Fourth Plan gave high priority to the industrialization of the western and southern parts of the country and the conversion of industries in other regions. The Fifth Plan had similar objectives, but added to these the development of metropolitan regions and an equilibrium in the development in each of them in order to provide a balance to the influence of the Paris region.<sup>347</sup> Regional planning has also become widely accepted in other developed market economies. Measures with respect to industrial location and the establishment and development of new towns have a long history in England.<sup>348</sup> Planning for urban conglomeration, development of the less industrialized regions, and the balanced distribution of population are elements of regional planning in the Netherlands.<sup>349</sup> Other countries such as Sweden, the Federal Republic of Germany and Japan provide incentives to workers who move to other less congested parts of the country.<sup>350</sup>

142. Regional planning has been increasingly accepted in recent years in many of the developing countries. Large projects for resource development have been or are being developed in a number of countries, such as the development of the Lower Mekong River Basin as a joint effort of the Governments of Cambodia, Laos, Thailand and the Republic of Viet-Nam,<sup>351</sup> the multi-purpose river valley development projects, such as the Damodar Valley, the Bhakra-Nagal and Hirahud pro-

jects in India,<sup>352</sup> the Gezira Scheme in the Sudan,<sup>353</sup> the Volta River hydroelectric project in Ghana,<sup>354</sup> the Aswan Dam in the Arab Republic of Egypt,<sup>355</sup> the Plan Lerma in Mexico,<sup>356</sup> and so forth. Colonization plans have been included in the plans of many countries including in Asia: Ceylon,<sup>357</sup> Pakistan<sup>358</sup> and the Philippines.<sup>359</sup> In Indonesia, special programmes of "transmigration" from overcrowded Java to colonization areas in Sumatra were elaborated as part of the country's regional development policy.<sup>360</sup>

143. Although in the plans of most developing countries, highest priority was given to speeding up the overall rate of economic growth, a number of plans contemplated certain measures aimed at a higher degree of income equalization in different regions or the acceleration of development in backward areas. In India's second plan, industrial development programmes which gave special consideration to the investment needs of underdeveloped areas were undertaken.<sup>361</sup> In the third plan, the development of backward areas was further to be enhanced through programmes for the expansion of small industries, the location of new enterprises, and the establishment of rural works programmes, especially in areas of high population density and limited development of natural resources.<sup>362</sup> The second five-year plan of the Republic of Korea, while continuing to promote large industrial complexes, simultaneously encouraged the establishment of medium and small industries in smaller cities.<sup>363</sup> In the plans of Pakistan it was recognized that the rate of development in East Pakistan was not as high as in West Pakistan and accordingly strong emphasis was laid on programmes to increase agricultural produc-

tion and develop industries in East Pakistan.<sup>364</sup> The second five-year plan of Thailand provided for regional development programmes for five geographical regions of the country and also outlined measures and programmes for the development of remote and backward rural areas.<sup>365</sup> In Africa, the development plan of Kenya noted the problems of balanced development between geographical areas and considered such measures as rural development services, land consolidation and resettlement schemes.<sup>366</sup> In Nigeria, three regional development plans were elaborated together with the Federal Plan.<sup>367</sup> A number of other countries in the region, among them the Ivory Coast, Morocco, Senegal and Tunisia, emphasized in their plans the need for a more effective co-ordination of efforts and programmes at the local, regional and central levels.<sup>368</sup>

144. In Latin America the problem of regional development has received special attention in the case of north-eastern Brazil. The programme for this region contemplated the promotion of industrialization and the expansion of its agricultural boundaries through the expansion of irrigation and the incorporation of unoccupied lands. In order to increase migration to these latter areas, the plan initiated an investment programme in infrastructure and provisions for the transportation, housing and other facilities for the migrant families.<sup>369</sup> Venezuela's plan for 1963-1966 included among its principal objectives the utilization of the resources of the different regions of the country in the most efficient way possible.<sup>370</sup> A specific programme in this connexion was the development of a heavy industry complex in Guayana based on the region's natural resources such as iron ore, hydroelectric power and natural gas. The development of these resources, considered as an integral part of the country's industrialization programme, was expected to draw a large number of workers and other immigrants into the area and especially to the city of San Tomé de Guayana.<sup>371</sup>

145. Despite the importance assigned to regional development and its planning in many countries, relatively little attention has been paid to the role of demographic factors in the preparation and formulation of plans. This is partly due to the less than complete integration of regional planning with planning in general; it is also partly a consequence of a less than complete understanding and knowledge of the role of demographic factors in regional planning. Nevertheless, recent literature has revealed an increasing interest in and preoccupation with demographic factors in regional development and its planning.

### E. Family planning programmes and development planning

146. High rates of population growth and the characteristics associated with it, as has been noted before in this and the preceding chapters,<sup>372</sup> may constitute a serious challenge to rapid economic development. It is claimed that the unprecedented increase in population taking place in many developing countries not only requires a high rate of economic growth in order to attain sustained and significant raises in levels of income, but also exerts a strong pressure on available resources, thus severely limiting the goals they can set for economic development and social progress. It is for these reasons that a number of countries in the process of development have considered and adopted as part of their development efforts a population policy aimed at reducing the rate of population growth through fertility decline. Since population policies as such will be discussed in another chapter,<sup>373</sup> this section deals only with some general considerations of such programmes in the context of development planning and the practices concerning the incorporation of family planning programmes in national plans in selected countries.

147. Although apart from some pioneering efforts, the incorporation of family planning programmes in national planning is a relatively recent phenomenon and has gained considerable acceptance over the last few years. In the early 1960s, few countries considered family planning programmes as an integral part of their development policies. An inquiry among Governments on problems resulting from the interaction of economic development and population changes at that time revealed that although a considerable number of Governments were concerned with the implications of high rates of growth of population, few had incorporated family planning programmes in their development plans.<sup>374</sup> By the end of the decade, family planning programmes had been initiated in many countries and such programmes formed to an increasing extent an integral part of the national plans.<sup>375</sup>

<sup>372</sup> See especially chapters XIII and XIV.

<sup>373</sup> See chapter XVII.

<sup>374</sup> United Nations, *Inquiry among Governments ...* (1964), pp. 8-12.

<sup>375</sup> See chapter XVII. United Nations, *World Economic Survey, 1968*, part I ... (1969), p. 8, noted that, at least in several of the developing countries, the present official sponsorship of family-planning programmes contrasts with the negative attitude when the question of family planning first emerged.

148. Family planning programmes in the context of national planning have received special attention in relation with the Second United Nations Development Decade. The proposals for the Decade implicitly assumed, in setting its objectives, that measures should be taken to reduce the average birth-rate, as a minimum, at an equal pace with the declining levels of mortality. "What is called for", it is stated, "is the implementation of a population policy which is effectively conceived to influence the main determinants of demographic growth."<sup>376</sup> The action programme for the Second United Nations Development Decade noted in that context that each developing country should formulate its own demographic objectives within the framework of its national development plan. "Those developing countries" it was stated in more general terms, "which consider that their rate of population growth hampers their development will adopt measures which they deem necessary in accordance with their concept of development."<sup>377</sup> Another study,<sup>378</sup> also dealing with the problems of future development, noted that societies which have learned to control mortality have to face the need to control birth and recommended that developing countries, after identifying their population problems, recognize their relevance to their social and economic planning and adopt appropriate programmes. In discussing the developments of the 1960s and the problems in Asia of the Second United Nations Development Decade, it was observed that in view of the rapid growth of population in the majority of the countries of the region, measures to control such growth should not be under-estimated.<sup>379</sup> In connexion with the Development Strategy for the Second United Nations Development Decade (General Assembly resolution 2626 (XXV)) in Latin America, it was noted that a decline in the birth rate would help in attaining the basic objective, that of raising the levels of living of the majority of the population over a shorter time period than otherwise and that programmes for providing the information on means to decide on the size of the family would accelerate the demographic transition.<sup>380</sup>

149. At the same time it has been recognized that family-planning programmes do not themselves solve the problems faced by the developing countries and that such programmes should form part of the national development efforts and planning. In considering some of the issues of development policy in the decade of the 1970s, it was emphasized that family-planning programmes are only one of the complex of measures for promoting human welfare. In particular, it was asserted that such programmes should not be considered substitutes for other measures to accelerate economic growth and social

progress.<sup>381</sup> A similar view is reflected in the discussion with respect to Asia, where it is stated that measures for population control do not replace measures aimed at raising output, but are only one among all policies for increasing economic growth.<sup>382</sup> With respect to Latin America, it was also stressed that the nature and magnitude of the development problems of the region are such that decreasing fertility would in no way do away with the need for rapid economic development.<sup>383</sup>

150. The first among the developing countries to consider an active policy with respect to population within the context of development planning was India. The First Five-Year Plan (1951-1956), taking into consideration the rapid increase in population and the pressure of population on resources, stressed the need for a curb on population growth as an important condition for a rapid improvement in levels of living. The plan formulated a programme in this field which included services; field experiments of different techniques for family planning; education in family planning methods and research on fertility; and the interrelationships between economic, population and social changes.<sup>384</sup> The Second Five-Year Plan (1956-1961) proposed to develop this programme further and to establish one clinic for each 50,000 people in the big cities and major towns.<sup>385</sup> The Third Five-Year Plan (1961-1966) stated that the objective of stabilizing the growth of population must be at the very centre of planned development and that the greatest stress had to be placed on family-planning programmes. Among the major aspects of the family-planning programme, the plan mentions the importance of the organization and of the personnel of the programme, the need to expand family-planning services and the mobilization of available agencies for education and extension work.<sup>386</sup> The Fourth Five-Year Plan (1966-1971) affirmed the recognition of family planning as a key element in the country's development and adopted as the objective of a nation-wide programme the reduction of the birth rate from 40 per thousand at the time to 25 per thousand as soon as possible. The operational goal for achieving this objective was to create facilities for 90 per cent of the country's married population.<sup>387</sup>

151. The First Five-Year Plan (1955-1960) of Pakistan noted the desirability of the extension of family-planning facilities and allocated resources for programmes in this field.<sup>388</sup> The Second Five-Year Plan (1960-1965) recog-

nized the need for a conscious population policy and its implementation and accordingly formulated a programme primarily designed to influence social attitudes and practices.<sup>389</sup> The Third Five-Year Plan (1965-1970) set as an objective the halving of the birth rate in the next 25 years and within the third plan period from 55 to 45 per thousand.<sup>390</sup> A number of other Asian countries have considered family planning programmes in their national plans. The Ten-Year Plan of Ceylon accepted the possibility of influencing fertility through public policies and noted that a beginning had been made with a family planning campaign.<sup>391</sup> The First Five-Year Plan of the Republic of Korea (1962-1966) noted the need for population control measures<sup>392</sup> and in the Second Five-Year Plan (1967-1971) the development of an effective family-planning programme was closely associated with the major targets of the plan, which envisaged a fall in the rate of population growth from 2.7 per cent in 1965 to 2.0 per cent in 1971.<sup>393</sup> The First Malaysia Plan (1966-1970) noted that a new policy was to be adopted in the implementation of a positive programme for family planning.<sup>394</sup> The Third Plan of Iran, commenting on the rapid growth of the country's population and its implications for development, concluded that for both economic and welfare considerations family planning should constitute one of the important welfare programmes.<sup>395</sup> The First Five-Year Plan (1963-1967) of

Turkey noted that whereas in the past population policy had aimed at increasing population, existing obstacles to population planning should be removed.<sup>396</sup>

152. The tendency to consider family planning programmes as part of national development policy is also growing in Africa. In the case of Ghana, a population policy and programme were viewed as integral parts of social and economic development policy.<sup>397</sup> The Development Plan (1966-1970) of Kenya noted that the population problem had such serious consequences for future development that strong emphasis would be placed on measures to promote family planning education.<sup>398</sup> The Four-Year Plan (1965-1968) of Tunisia observed the need to take action to educate people and to encourage them to adopt voluntary birth control.<sup>399</sup> Family planning programmes have been actively considered in only a few plans of Latin American countries. The guiding principles for national development in the period 1970-1980 of Panama affirmed that a population policy constitutes a basic factor in the formulation of any development strategy.<sup>400</sup> A similar point of view is found in the Economic and Social Development Plan (1970-1973) of Colombia, which notes, commenting on the population problem of the country, that the existing and future development create the need for adopting a population policy adapted to the society's needs and aspirations.<sup>401</sup>

## Chapter XVII

### POPULATION POLICIES

1. Among the significant phenomena of the 1960s was the emergence of population matters to a place of paramount importance in the writings of social scientists and in the deliberations of Governments. Questions relating to population policies, in particular, became the focus of much attention. There had been previous periods during which interest in population matters stimulated national and international debates. Especially noteworthy was the nineteenth-century literary exchange that revolved around the writings of Thomas Malthus, who observed that population tended to increase more rapidly than the means of subsistence.<sup>1</sup> But after a secular decline that began in the latter part of the nineteenth century, birth rates fell to unprecedented low levels in most countries of Northern and Western Europe and Northern America under the influence of depressed economic conditions in the 1930s. By this time, concern for high rates of population growth had totally abated and, in fact, it was the spectre of possible declining population in the industrialized nations which engaged the attention of scholars.

2. The increase in the birth rate during and after the Second World War in many of the developed countries allayed concern over low population growth rates in some countries, although others displayed an interest in promoting population growth. The demographic situation in the developing countries, meanwhile, was changing dramatically in the post-war period. The introduction of medical technology and public health measures, along with some improvements in social conditions, brought about substantial declines in mortality in many areas of the developing world, while fertility showed little change, or in some instances increased. The declining mortality coupled with high fertility resulted in rapid population growth, and by the 1960s concern over population problems had come to focus on the developing countries. Anxiety over the consequences of this accelerating population growth gave rise to an international exchange on questions of population policy and the efficacy of alternative action programmes. These discussions on what might be considered as appropriate population policies have reflected differing conditions, philosophies and goals, the state of knowledge about the inter-relationships between demographic, economic and social phenomena, as well as humanitarian considerations and views on what constitutes a population policy.

3. The debates in various United Nations bodies eventually led to a series of decisions such as those set

forth in General Assembly resolution 2211 (XXI) of 17 December 1966 which called for an expanded United Nations programme of activities in population; the declaration of Heads of State or Prime Ministers of thirty Governments presented to the United Nations on Human Rights Day in 1967 which proclaimed as a basic human right the opportunity for parents to decide the number and spacing of their children;<sup>2</sup> and the International Development Strategy for the Second United Nations Development Decade (General Assembly resolution 2626 (XXV)) which, *inter alia*, called upon developed countries and international organizations to provide assistance upon request to developing countries which have adopted measures to modify their rates of population growth. The various resolutions and statements adopted have enunciated several important principles which reflect the diverse demographic situations and attitudes. These principles include the sovereignty of nations in formulating population policies, the free choice of the individual family in determining family size, the role of population policy as an integral component of broad national development policies, and the assurance that international assistance granted to Governments in the implementation of population policies will in no way be a substitute for other forms of development assistance.<sup>3</sup> While international agencies had at an early stage assumed a role in assisting Governments of developing countries in implementing policies in other areas (for example, with respect to health, education and employment), the idea of United Nations assistance to Governments wishing to moderate their population growth has gained wide acceptance only recently.

4. This chapter first considers definitions of population policy and its relationship to social and other policies. It then summarizes the history of policies affecting fertility prior to the Second World War and discusses the content and impact of post-war policies and measures affecting fertility in the developed and developing countries.

#### A. Population policy and its relation to other policies

##### 1. DEFINITIONS OF POPULATION POLICY

5. Policy in general has been defined as a set of objectives along with the measures and means to achieve them.<sup>4</sup> What constitutes a population policy has been

<sup>1</sup> See the discussion in chapter III.

<sup>2</sup> United Nations, *Population and its Relation . . .* (1968), para. 8 and annex I.

<sup>3</sup> United Nations, *Population and the Second . . .* (1971), para. 2.

<sup>4</sup> See, for example, Macura, "Síntesis de las ponencias presentadas" (1972), p. 266.

variously conceived by different writers on the subject, and no generally accepted definition has as yet emerged. Part of the difficulty no doubt stems from the problem of defining the field of demography itself, since some scholars have adopted a narrow definition which includes only the study of the size, distribution and composition of population and its components of change, while to others demography is also concerned with the relationships between population and social, economic and other variables.<sup>5</sup> Similarly, population policy may be viewed either in the narrow sense as being concerned only with efforts to affect the size, structure, distribution or characteristics of the population, or—in recognition of the interrelationships between population and economic and social change—it may be conceived of in the much broader sense of including also efforts to regulate economic and social conditions which are likely to have demographic consequences.<sup>6</sup>

6. Many writers have adopted a definition of population policy which is narrow enough to be capable of focus and orientation within the concept of general economic and social policy-making and planning.<sup>7</sup> In the opinion of Spengler and Duncan, for example, a population policy is a specific set of government objectives relative to the population magnitude and/or composition along with the instruments by which it may be possible to achieve those objectives.<sup>8</sup> This view appears to have wide currency.<sup>9</sup> After reviewing a cross-section of the relevant literature, Eldridge defined population policies as legislative measures, administrative programmes, and other governmental action intended to alter or modify existing population trends in the interest of national survival and welfare. She recognized that many aspects of public policy influence demographic phenomena and considered that population policy embraces those aspects of general social policy that are designed to “counteract unwanted demographic effects of over-all public policy or of other social forces”.<sup>10</sup> Population policy is thus understood, in the more restricted sense, as positive, deliberate action by government taken expressly to facilitate achievement of adopted goals<sup>11</sup> relative to population size, growth and composition in the interest of national well-being.

7. One of the themes running through these definitions is that of “deliberate intent”. The “deliberate intent of a

group to control its size and/or its characteristics” is the criterion singled out by Thompson and Lewis for determining the existence of a population policy.<sup>12</sup>

8. More broadly, some writers have considered economic and social measures which influence population trends to be an aspect of population policy. A summary of an article by Acsádi states that “population policy is conceived nowadays in a broader sense; it includes not only the conscious and direct influencing of the population processes but also all the social and economic measures which exercise an influence—even in an indirect way—over the characteristics and processes of the population. A population policy cannot be abstracted from an economic and social policy, as it has to consider the factors which affect the population changes and also the consequences arising from the population changes.”<sup>13</sup> Sauvy has written that certain objectives of population policy embrace economic, social and cultural policy as well.<sup>14</sup> Hauser has also acknowledged that population policy may, under certain conditions, appropriately comprise social and economic development policy,<sup>15</sup> while Doublet considered that distinctions between demographic and other measures of social and economic significance were frequently artificial.<sup>16</sup> In Boyarsky's view, population policy consists of a system of measures affecting demographic processes, but it should not be separated from general socio-economic policy as it is an aspect of over-all policy.<sup>17</sup>

9. Since population policy is so often considered to be a closely related aspect of general socio-economic policy, specifications of population policy have frequently been integrated into general programmes of economic and social development.<sup>18</sup> This is not to suggest that exclusive reliance on economic and social development is viewed by many as an instrument for implementing population policy. Such development is generally considered to be a goal in itself, although it is known to be frequently accompanied or followed by demographic change.<sup>19</sup>

<sup>12</sup> Thompson and Lewis, *Population Problems* (1965), p. 527. Organski and Organski also emphasize that population policy is deliberate, and add that it is planned and put into effect by national Governments because only in this way can the behaviour of a whole community be influenced. Organski and Organski, *Population and World Power* (1961), pp. 181-182.

<sup>15</sup> Hauser, “Non-family planning methods . . .” (1969), p. 65.

<sup>16</sup> Doublet, “Des lois dans leurs rapports . . .” (1949), pp. 40-41.

<sup>17</sup> Boyarsky et al., *Kurs demografii* (1967), p. 32.

<sup>18</sup> See, for example, Ghana, *Population Planning for National Progress and Prosperity* . . . (1969), p. 19; Tunisia, *Plan quadriennal, 1965-1968* . . . (1965), p. 20; Smulevich, “K voprosu o zakone . . .” (1967), pp. 20-26; Notestein, “The population crisis . . .” (1967); Guzevatyi, *Programy kontrolya* . . . (1969), pp. 59-63.

<sup>19</sup> The importance assigned by some scholars to economic development alone as a factor in fertility decline has been questioned. Referring to what she terms the development school of thought, Blake points out that application of socio-economic development as a population policy is “clearly open to objections of both a scientific and practical nature”. Blake, “Demographic science . . .” (1965), p. 42. She emphasizes that modernization alone “has nowhere in the world to date had an abiding and drastically downward effect on family size desires”. *Ibid.*, pp. 43, 59.

<sup>5</sup> Hauser and Duncan used the terms “demographic analysis” and “population studies” to distinguish between the narrow and broad concepts respectively. See their “Overview and conclusions” (1959), pp. 2-3.

<sup>11</sup> Macura, “Síntesis de las ponencias presentadas” (1972).

10. Among the factors which have been frequently mentioned as falling within the scope of population policy are population size, rate of growth, levels of fertility and mortality, proportion married, the regulation of international and internal migration, sex and age structure, the utilization of human resources and the eugenic quality of the population. Some of these factors serve as means for influencing other variables, however, whereas others represent ends in themselves. For example, the lowering of mortality is considered a desirable goal in itself, whereas influencing the level of fertility is desired for its effect on growth rates and population size, and international migration policies may be used to modify population size or characteristics such as sex and age structure.

11. The Population Commission of the United Nations, at its sixteenth session, in 1971, favoured a concept of population policy which "includes not only objectives and measures aimed at fertility regulation, and the supporting family planning programmes, but also objectives and measures designed to extend longevity, i.e., to reduce high mortality and morbidity, in general, and infant and childhood mortality, in particular."<sup>20</sup> As conceived by the Commission, population policy should be concerned not only with the desirable rate of population growth, but also with the structure of the population and its distribution, particularly in urban and rural areas. The definition of population policy promulgated at a 1967 meeting on population policies in relation to development in Latin America specified that such policies may influence "the probable size and growth of the population, its age make-up, mortality rates, the formation and composition of families, the regional or rural-urban distribution of the people, and their admission to the labour force and to education . . .".<sup>21</sup>

12. According to Eldridge, "the major purpose [of population policy] is to control population size, but consideration may also be given to influencing its composition and its geographic distribution".<sup>22</sup> She emphasized quantitative aims of population policy since the inclusion of qualitative aims would make population policy virtually indistinguishable from public policy in general.<sup>23</sup> Sauvy, on the other hand, considers qualitative aims—such as providing satisfactory living conditions for the least fortunate classes—as an appropriate objective of population policy.<sup>24</sup> One recent study has distinguished two types of "population-related" policies: the first, designated as "population-responsive" policies, aims at

qualitative improvements through general development efforts, while the second, termed "population-influencing" policies, attempts to influence one or more of the demographic variables.<sup>25</sup>

13. While writers in the USSR generally consider that population policy may be concerned with influencing the components of population growth, some have particularly emphasized the role of policy in shaping the geographic distribution of the population and its productive employment. Kvasha noted that, while policy concerning mortality has an obvious direction, policy with respect to fertility should be aimed at achieving an optimum replacement of the population. Policy should also be designed to influence the pattern of internal migration to attain an advantageous distribution of labour resources, as well as for the effect of population distribution on the reproduction of the population.<sup>26</sup> Boyarsky wrote along similar lines, calling attention to the fact that conscious population policy can be directed towards either increasing or diminishing the rate of population growth, as well as towards changing the geographic distribution of population.<sup>27</sup> According to Smulevich, scientifically well-founded population policies could play a role both in promoting the rational reproduction of population and the rational utilization of labour resources.<sup>28</sup> Sonin pointed out that, since the means of production in socialist societies are collectively owned, it is possible to consciously plan and regulate national production and its distribution in such a way as to provide for the most rational employment of the labour force in the different branches of the economy and in the different economic regions of the country.<sup>29</sup>

14. The control of population size may theoretically be mediated through any of the three components of population change—fertility, mortality and migration.<sup>30</sup> The mortality component is unique, however, in that the reduction of mortality is a universal aim of Governments, including those whose policy it is to slow down their rate of population growth. To quote Eldridge: "Manipulation of the death rate in order to control the rate of growth is not feasible, because there is only one policy in relation to mortality that is socially acceptable—namely, to reduce it."<sup>31</sup> In her view, measures designed to reduce mortality should not be considered as population policy, but rather as health policy, since their purpose is to improve the health of the population rather than to affect the rate of population growth.<sup>32</sup>

15. Legislation regulating international migration is almost universal among nations. Such legislation may

<sup>20</sup> See *Official Records of the Economic and Social Council, Fifty-second Session, Supplement No. 3*, para. 52.

<sup>30</sup> See, for example, Organski and Organski, *Population and World Power* (1961), p. 181.

<sup>31</sup> Eldridge, "Population policies" (1968), pp. 383-384.

<sup>32</sup> Eldridge, "Population policies" (1968), pp. 383-384. Some of the measures specifically employed to improve unfavourable health conditions are discussed in chapter V.

influence migration in an upward or downward direction. Population policy may also be directed towards the redistribution of population within national boundaries.<sup>33</sup> Migration policy is more controversial than policies affecting health and mortality in that it may involve coercion and restriction of movement on an individual level, and may create tensions between countries because of quota systems or such phenomena as the outflow of trained professional and technical personnel from one country to another.

16. Since policies aimed at lowering mortality are universally valued, and international migration on a scale sufficient to solve the population problems of developing regions cannot be considered a practical possibility, it is inevitable that present-day population policy should focus on the remaining component of population growth—fertility. Eldridge has pointed out that “practical considerations are such that most of population policy, as it exists today, is directed at influencing fertility...”.<sup>34</sup> Various recent studies have reflected this tendency,<sup>35</sup> and it is with this subject that the present chapter deals. This emphasis is justified by the decision of approximately thirty-five countries to initiate action programmes in this sphere. In addition, many other Governments have been concerned with the implications of their social policies for fertility trends.<sup>36</sup>

17. Measures affecting the biological quality of the population involve almost exclusively the science of eugenics, while such qualitative aims as the one mentioned by Sauvy are more appropriately the target of social, rather than population policy. Both of these aspects of policy are considered beyond the scope of the present text.

18. Even more problematic than delineating the scope of population policy is the question of determining whether or not a population policy exists in various countries. Some of the questions which come to mind in this connexion are the following:<sup>37</sup>

(a) Does there have to be an authoritative statement by a responsible government official or legislative body that a population policy has been adopted?

(b) May the goals of the policy be stated only broadly, or must they be precisely elaborated?

(c) Is a government statement alone sufficient, or must there be evidence that legislative measures have been adopted and machinery has been set up to implement the stated policy?

<sup>33</sup> Policies with respect to internal and international migration are discussed in chapters VI and VII respectively.

<sup>34</sup> Eldridge, “Population policies” (1968), p. 382.

<sup>35</sup> For example, Lyons assumes that “population policy refers primarily to population growth limitation based on a *voluntary fertility regulation concept*...”. See his “Population policies: a world overview” (1971). See also Nortman, “Population and family planning programs...” (1970), p. 12.

<sup>36</sup> United Nations, *The World Population Situation in 1970* (1971), chap. 7; Family Planning Federation of Japan, *Harmful Effects...* (1966); Acsádi, “Népességgpolitikai kérdések...” (1969); Raina, “Possible effects of public policy...” (1965), pp. 100-104.

<sup>37</sup> Several of these questions were suggested by Lyons’ article, “Population policies: a world overview” (1971).

(d) In the absence of a government statement, does Government support for (or non-interference with) the endeavours of private organizations to influence population trends constitute population policy?

(e) If the stated purpose for the establishment of a government family planning programme is to reduce the incidence of illegal abortions or to enable families to have the number of children they desire, rather than to reduce fertility or the rate of population growth, can this be defined as population policy?

(f) Do indirect measures to influence population trends (e.g. through increasing literacy, raising the status of women, and generally promoting social and economic development) constitute population policy?

(g) In the presence of measures tending to have opposing effects on population trends, how can the policy measures—if any—be distinguished from measures adopted for health, social or humanitarian purposes? An example would be a country which provides strong support for the family through family allowances, liberal maternity benefits and services for children, but which at the same time has a permissive policy towards abortion and contraception.

19. Given the various definitions of population policy discussed above, the difficulty of determining whether or not a Government is pursuing such a policy is apparent, as a population policy may remain unarticulated in a formal sense.<sup>38</sup> This does not necessarily imply the absence of an implicit policy, which, for a variety of reasons, a Government may not wish to make explicit. In this connexion, for example, a Government may not take any steps on a governmental level to implement its implicit policies, but may direct funds and other forms of support to private agencies working towards the desired ends. Or, legislative as well as other measures may be adopted to facilitate the desired demographic goals without these goals being spelled out. Another factor which may obscure a Government’s population policy is the fact that the scope of a Government’s activities is very broad, and its social or public programmes may actually result in what it considers to be undesirable population changes, if these programmes have been formulated to satisfy other considerations, e.g. to promote health, social justice and free choice among the population. It may therefore be difficult to disentangle the population aspects of its policy from these other elements.

20. Some writers have pointed out that the absence of specific measures to influence population is in itself a form of population policy. Parkes and his colleagues, for example, proposed that the implied assumption in such cases is that conditions and trends of population “should be taken as given—as a factor, variations in which are simply accepted”,<sup>39</sup> and Lyons has written that it may

<sup>38</sup> Writing of social policies, Kent has noted that while “social policies are sometimes enunciated in legislative acts, court decisions, and executive messages, more often [they]... must be inferred from actions; for social policy means the set of guidelines which people use in selecting courses of action and, by and large, these guidelines are not explicitly stated”. Kent, “Social services and social policy” (1966), p. 202. This statement may also be applied to population policy.

<sup>39</sup> Parkes *et al.*, eds., *Towards a Population Policy...* (1970), p. 7.

be unreasonable to say a Government has a population policy only when it acts, for in fact the inaction of another Government may also strongly imply a deliberate policy.<sup>40</sup>

21. Two recent studies have suggested that the main criteria which ought to be met in order for a Government to be counted as having a population policy are first, that there must be a declaration of policy at a responsible governmental level, and second, that some measures must have been taken to implement the policy.<sup>41</sup> In the present chapter the course adopted is to identify, wherever possible, those countries which have policies to raise or lower fertility as defined by these two criteria. However, it would be unduly restrictive to exclude discussion of programmes and measures which might affect fertility although they were not explicitly framed for policy reasons. Therefore, selected measures and programmes having the potential to significantly influence fertility have been included in the discussion where relevant, irrespective of the purpose for which they were formulated. Such measures may have been designed to facilitate voluntary parenthood, improve maternal and child health, and raise the status of women, to mention a few.

## 2. RELATIONSHIP TO SOCIAL AND ECONOMIC POLICY

22. Because of the close interrelationships between demographic, economic and social characteristics and changes, the formulation of government policies in any of these areas needs to be based on an understanding of the probable effects on other factors. Meade and others have pointed out that, owing to the insufficient attention given to the study of these interrelationships, policies with direct demographic effects (for example, those related to the medical services) and other social policies which have indirect demographic effects (such as those relating to education, family assistance, housing etc.) are determined without full consideration of the economic consequences of the demographic changes which they may cause. At the same time, economic and financial policies are often formulated without due regard for their demographic implications.<sup>42</sup>

23. Since population is only one of a multitude of areas of concern to Governments, it is often difficult, if not impossible, to distinguish the strictly demographic aspects of policy affecting population from the social aspects. At the same time, there may be apparent contradictions between policies formulated with different aims in mind. As an example of the first, a system of family allowances and other benefits to mitigate the burdens of child-bearing and rearing may be instituted to stimulate population growth, for humanitarian reasons, or both. As an example of the second, a Government pursuing a pro-natalist policy by encouraging large families through various incentives may at the same time support policies

which tend to lower fertility. Such a Government may permit or even provide family limitation materials and services to facilitate voluntary parenthood; abortion may be legalized as part of a health programme in order to counteract the health hazards associated with illegal abortion; and the same Government may also promote improvements in the status of women as an element of social policy, and may attempt to engage women in an active economic life as part of an economic policy for maximizing the labour force.

24. Several authors have commented on the inconsistencies which often appear in national policies in the demographic, economic, health and social fields and which result from the fact that policy is formulated in response to a variety of different needs and can rarely serve a single purpose. Eldridge explains that, for a variety of reasons, States are required to violate some of their interests while serving others, and that the decisions with which they are confronted frequently involve the weighing of one desirable aim against another. In her opinion, it is "small wonder that the body of national policy often contains contradictions and inconsistencies some of which are real and some of which are only apparent . . .".<sup>43</sup> Glass observed that "social policy is never single-minded and rarely fully consistent" and noted that "even if there is no inconsistency as regards major objectives, measures may nevertheless be incompatible as regards their effects".<sup>44</sup> The complex nature of society and the demands for democratic processes appear to make inevitable some contradiction of goals, but in order that national policy can reflect a certain degree of coherence, a harmonizing of conflicting interests must be achieved. Myrdal has argued that population policy must be weighed in relation to the many other values and goals of society, and that out of such a process socio-economic and demographic reforms can be fused into a whole.<sup>45</sup>

## 3. ETHICAL ISSUES

25. The right of each sovereign nation to formulate and pursue its own population policies has received wide recognition.<sup>46</sup> Such policies are conceived and implemented for what Governments consider to be the common good: the underlying reasons for a nation's wishing to influence demographic factors generally include the improvement of economic and social conditions, although at times political, military and power objectives have been dominant.

26. As nations have increasingly evolved policies with respect to fertility in recent years, there has been much concern and discussion as to the extent to which Governments may properly interfere in such matters, which involve the most intimate decisions on the part of individuals. A certain broad consensus has been reached that, while Governments have the right to formulate their own

<sup>46</sup> See, for example, United Nations General Assembly resolution 2211 (XXI); International Conference on Human Rights resolution No. XVIII on human rights aspects of family planning, Teheran, 12 May 1968.

policy in this area, persuasion and education, rather than coercion, should be employed to influence reproductive behaviour. National policies are thus aimed at the voluntary regulation of fertility, and most recent international policy statements emphasize the right of parents to decide the number of children that they will have and the intervals at which they will have them.<sup>47</sup>

27. In considering population policies for the United Kingdom, Parkes and his associates pointed out that the mention of "population policy" may evoke the terrifying prospect of governmental interference with the freedom of individual citizens in their most intimate personal decisions about family building. They proposed as a premise for decisions in this sphere that "any measures of 'population policy' should be based upon the freedom of individual citizens to determine the size of their family, subject only to the influence of such governmental measures as might by legitimate and acceptable means affect citizens' motives to have larger or smaller families".<sup>48</sup>

28. Other scholars have also made clear their opposition to coercive measures to induce the population to adopt contraceptive practice. Ovsienko, for example, has stated: "We are not opposed to producing contraceptive devices and supplying them to people who wish to use them, but we are opposed to the use of compulsion in this regard. In particular, we are opposed to extreme methods of reducing the birth rate, such as sterilization, which robs human beings of their dignity, has significant physiological and psychological effects on them, deprives them of their full worth and interferes with the full development of their personality."<sup>49</sup>

29. It has been emphasized by a number of writers that the freedom of families to have the number of children they desire—a basic precept of most family planning programmes—cannot be expected to yield automatically fertility levels or growth rates considered desirable on a national scale.<sup>50</sup> Coale has written: "We cannot count on the automatic effect of self interest to reduce the growth rate soon enough, even if contraception were universal and virtually perfect."<sup>51</sup> Kingsley Davis has also argued: "By stressing the right of parents to have the number of children they want, [family planning] evades the basic question of population policy, which is how to give societies the number of children they need. By offering only the means for *couples* to control fertility, it neglects the means for societies to do so."<sup>52</sup>

30. Recognizing the strong opposition to compulsory measures, Davis suggests as a solution that attractive

substitutes for family interests be developed. He would encourage factors leading to the postponement or avoidance of marriage, as well as those tending to limit reproduction within marriage. Among the measures mentioned for achieving these ends are a greater rewarding of non-familial roles, and the granting of certain economic advantages to single persons. In addition, he suggests payment to individuals who permit themselves to be sterilized, high fees for marriage licences, free abortion, a tax on children rather than tax exemptions for them, and a reduction of family allowances and of paid maternity leave. The provision of educational and employment opportunities for women equal to those for men would lead to a restructuring of the family and changes in the role of women.<sup>53</sup>

31. While Davis has for the most part avoided suggesting outright coercive measures, some other writers have considered the gravity of the population situation to be such as to warrant mass coercive action on the part of Governments in order to control population growth. Among the measures mentioned have been "mass use of antifertility agents (not yet invented) in the water supply or in staple foods; temporary sterilization of all girls at puberty and of women after each delivery by means of a time-capsule contraceptive . . . ; compulsory sterilization of males with three or more living children; compulsory abortions of illegitimate pregnancies."<sup>54</sup> Notestein, Kirk and Segal have specifically expressed their disapproval of such measures, stating that "coercive measures in control of family size intrude government prerogative into very private areas of life. One has only to recall the Nazi era in Europe to view with the greatest misgiving the adoption of any legislation giving government the authority for compulsory sterilization or mandatory control of family size."<sup>55</sup> Extreme measures have rarely been advocated by demographers, but since population policy is not necessarily formulated by demographers, nor even always based on their recommendations, it is important to take cognizance of all suggestions put forward—including those which may appear bizarre or offensive—for they may at some time receive serious consideration by Governments attempting to implement population policies.

32. It is clear from the various writings on the subject that the ethical criteria against which a given population policy ought to be evaluated have not yet been worked out; much serious and committed thought will be required for their development. The line between coercion and non-coercion is not easily determined, and is drawn

at a different point by different writers.<sup>56</sup> Berelson has raised the question of how much in ethical values a society should be willing to forego for the solution of a great social problem.<sup>57</sup> The problems posed are formidable and involve choosing from among several goods, deciding which is the least of a number of evils, determining how much of a sacrifice the present generation should make for the presumed good of future generations and, in Berelson's words, deciding "how best to reconcile individual and collective interests".<sup>58</sup> Among the propositions advanced for consideration in developing an ethical population limitation policy are that such a policy should move towards compulsion only as a last resort; that it would not penalize innocent children for the mistakes of their parents; and that it would not impose further hardship on the already disadvantaged, by denying them certain benefits if they over-reproduce.<sup>59</sup> While Berelson acknowledged that "the worse the problem, the more one is willing to 'give up' in ethical position in order to attain 'a solution'",<sup>60</sup> Coale has cautioned that "pre-occupation with population growth should not serve to justify measures more dangerous or of higher social cost than population growth itself",<sup>61</sup> and Dyck concluded that "it would be the ultimate irony of history if through our population policies we should lose precisely what we seek to save, namely, human rights and welfare".<sup>62</sup>

## B. History of policies affecting fertility up to the end of the Second World War

33. Until relatively recently in man's history, the natural increase in the population has been slow. Although fertility has been high, mortality has also been high, and

<sup>56</sup> Blake has implied that, in the absence of overt coercion, people may feel that their reproductive behaviour is voluntary. Nevertheless, implicit pro-natalist pressures exist which guide their choices in this sphere. In the face of these existing "pro-natalist incentives and coercions", she suggests a restructuring of choices and rewards so that individuals will "volunteer" for a different type of fertility behaviour. Blake, "Comment" (1970), p. 458.

<sup>57</sup> Berelson, "Beyond family planning" (1969), p. 8.

<sup>58</sup> *Ibid.* In this connexion Callahan has stated: "To decide that a particular kind of policy is needed (e.g. a voluntarist family planning policy or a quasi-coercive population control policy) is to make certain judgments about the relative ranking of important values, as well as to say something about the means appropriate to achieve final ends. All those judgments, in turn, presume that one has decided which values and goods are relatively more or less important for the living of a decent human life." Callahan, "Ethical issues" (1971), pp. 45-46. See also Coale, "Should the United States start a campaign for fewer births?" (1968), p. 471.

<sup>59</sup> Berelson, "Beyond family planning" (1969), pp. 8-9. See also National Academy of Sciences, *Rapid Population Growth, Consequences and Policy Implications*, vol. 1 . . . (1971), p. 81; Notestein, "Zero population growth" (1970); Day and Day, *Too Many Americans* (1964), p. 243. In Coale's opinion, "A program for increasing the number of children people want is more readily reconciled with humane goals than is a program for diminishing the number they want". This is because a pro-natalist policy usually provides certain benefits to families, whether in cash or in kind, whereas the converse of these measures cannot be considered an ideal means for lowering fertility. Coale, "Should the United States start a campaign for fewer births?" (1968), p. 473.

<sup>60</sup> Berelson, "Beyond family planning" (1969), p. 8.

<sup>61</sup> Coale, "Should the United States start a campaign for fewer births?" (1968), p. 472.

<sup>62</sup> Dyck, "Population policies and ethical acceptability" (1971), p. 636.

as stated in chapter V, the accumulation of many years' natural increase has often been swept away suddenly and rapidly as a result of famines, epidemics and wars. In order to ensure group survival, various customs and practices evolved which were conducive to high fertility. Among these were early and universal marriage, polygamy, and the practice of the levirate. The importance of bearing many children was impressed upon the populace by means of fertility rites as well as divine exhortations to be fruitful and multiply.

34. Official policies concerned with fertility trends appeared somewhat sporadically before the twentieth century, although many laws and measures affected fertility indirectly. Efforts to influence fertility were almost always "pro-natalist", that is, they aimed at increasing the birth rate.<sup>63</sup> The history of such policies is important as much for the light it casts on the conditions which have shaped them as for their demographic effects. These conditions lie partly in demographic trends and partly in changes in ideology, in economic circumstances and in the administrative capacity of Governments. Among the principal elements of pro-natalist policy were propaganda for bringing about the desired behaviour, the proscription of abortion, infanticide and contraception, the encouragement of marriage, and support for parents of large families.

35. Pro-natalist policies have been adopted for a variety of motives, including religious, military and those of power and economic considerations. Religious doctrines and institutions have exercised direct influence on behaviour determining fertility as well as indirect influence upon secular policies in this area. In some periods, such as that of the Middle Ages in Christian countries, the authority of the priesthood pre-empted areas of marital conduct now regulated by secular policy. In the ancient world, doctrines enjoining men to procreation were prevalent in China, India and Persia, though Buddhist and, less conclusively, Hindu thought held celibacy to be a higher ideal, if not one that most could attain.<sup>64</sup>

36. Religious teaching made procreation an element in the spiritual and social welfare of the individual and family as well as of the community. Military authority made it a duty to the State and its ruler. War and empire required, and could sustain, a growing population.<sup>65</sup> In classical Greece the warlike state of Sparta encouraged child-bearing for national ends, though favouring abandonment of unfit infants, while in the more democratic and commercial environment of Athens, and elsewhere, family limitation by abortion and infanticide were apparently practised and sanctioned. A number of Greek writers, most notably Plato and Aristotle, favoured policies for maintaining the population size considered to be most desirable for the city-state.<sup>66</sup>

<sup>63</sup> Glass, "Population growth and population policy" (1965), p. 4; Eldridge, "Population policies" (1968); United Nations, *The World Population Situation in 1970* (1971), chap. 7.

<sup>65</sup> Gonnard, *Historia de las doctrinas de la población* (1969), p. 19.

<sup>66</sup> Stangeland, *Pre-Malthusian Doctrines of Population* (1904), pp. 18-28.

37. The best known of ancient population policies were those of the Roman emperor Augustus, embodied principally in the *Lex Julia et Papia-Poppea*, enacted between 18 B.C. and A.D. 9. These policies penalized the celibate or childless and favoured parents in the application of inheritance law and eligibility for public office. They were intended to restore the fertility of the senatorial class, and later emperors extended their application.<sup>67</sup> The effects of Roman policy on fertility cannot be determined, for, while the population of the early Empire probably rose, little is known about fertility trends or differentials (see chapter II, section B). Some historians have claimed that these laws were ineffective and they were eventually abrogated in the reign of Constantine.<sup>68</sup> The Augustan laws are most remarkable in that they modified the earlier social structure and hence the social and legal context of marriage and fertility. They served as a model for population policy for later periods.<sup>69</sup>

38. Less is known of population policies adopted by the rulers of other States in the ancient world, although values and customary practices both favourable and unfavourable to fertility were present throughout pre-modern times.<sup>70</sup> Moreover, there is evidence of an awareness of the relationship between population and resources and of the need for adjustment of that relationship.<sup>71</sup> However, the fluctuations of population in response to harvests and disease reduced the need to modify fertility, while the limited administrative capacity of rulers and the inertia of custom hampered the effectiveness of measures intended to alter fertility levels and trends in pre-modern societies.<sup>72</sup>

39. These factors and the influence of the Christian church, which emphasized other-worldly values, the ideal of celibacy, and ecclesiastical against national authority, left little scope for secular population policies in Western countries in the Middle Ages. Christian condemnation of abortion and infanticide may have balanced the advocacy of celibacy and restraint, while at a local level the power of feudal lords and guilds sometimes extended to regulation of marriage,<sup>73</sup> but these influences did not constitute national population policies.

40. Such policies were revived with the growth of more centralized monarchical States in Europe. Heavy mortality caused by the Black Death in the fourteenth century and the slow recovery of numbers encouraged populationist views and policies. In France, tax exemption and other privileges were employed to encourage immigration and fertility beginning in the late thirteenth century.<sup>74</sup> More comprehensive pro-natalist policies emerged in

France and Spain in the seventeenth century, supported by mercantilist doctrines which advocated state intervention to secure the wealth and power believed to derive from a large population (see chapter III, section B). In Spain, an edict of 1623, intended to restore the population losses of the previous century, granted tax exemptions to those who married young and raised large families. Its execution seems to have fallen short of its intention, although it remained in force until the end of the eighteenth century.<sup>75</sup> French policy reached its apogee under Louis XIV's minister, Colbert, whose 1666 edict provided tax exemptions for early marriage and pensions for the fathers of ten or more living legitimate children, and tried to limit religious celibacy. The secular and economic goals of this policy were undermined by poor administration and by the military and religious policies of Louis XIV, which led to the emigration of Protestants and a period of high mortality and population decline following the revocation of Colbert's measures in 1683.<sup>76</sup>

41. Other European States, among them Savoy, Austria, Prussia and other German States, adopted a variety of pro-natalist measures in the seventeenth and eighteenth centuries. These included discrimination in favour of married men or fathers in admission to trades or public offices and in inheritance laws, and the removal of limitations on the right of soldiers to marry, and on the rights of illegitimate children.<sup>77</sup> Abortion and infanticide were forbidden by law in European States and contraceptive practices were condemned by religion, but there is little information on the effectiveness of these policies or on the use of these means to restrict family size.

42. Many Russian statesmen and scientists of the seventeenth and eighteenth centuries generally favoured an increasing population.<sup>78</sup> but it was Lomonosov who outlined and submitted to the Government the first comprehensive population policy.<sup>79</sup> In his memorandum on the "preservation and multiplication of the Russian people" (1761) he suggested that the grandeur, opportunity and wealth of the State lay in its people and their productivity. He pleaded for better conditions for infants in order to lower infant mortality, for improvements in medicine and public health, for health education and education in general. He condemned traditional religious beliefs and prejudices detrimental to health and suggested that adequate nutrition and diet were essential for a healthy population and particularly for youth. Assuming that his reforms would be implemented, he anticipated a more rapid growth of the Russian population.<sup>80</sup>

<sup>77</sup> Glass, *Population Policies and Movements* ... (1940), pp. 95-96. Knodel, however, pointed out that pro-natalist policies in the German States during this period were not unqualified, and certain restrictions on marriage were imposed, as concern about pauperism developed. See his "Law, marriage and illegitimacy ..." (1967), pp. 279-280.

<sup>78</sup> Valentei, *Problemy narodonaseleniia* (1961), pp. 41-55.

<sup>79</sup> Lomonosov, mentioned in *ibid.*, p. 48.

<sup>80</sup> Valentei, *Problemy narodonaseleniia* (1961), pp. 48-49.

43. In Japan, too, measures designed to stimulate population growth were adopted during the eighteenth and nineteenth centuries, but their effects were to some extent checked by widespread resort to infanticide, abortion and delay of marriage. Neither exhortation, attacks on anti-natalist practices nor positive assistance to parents seems to have been enough to remedy the general stagnation of population in the absence of more fundamental economic and social changes.<sup>81</sup>

44. As mortality began to decline in response to the improved living conditions made possible by the agricultural and industrial revolutions, population pressures built up in certain areas and stimulated efforts to control further growth. In a number of German States, where population was growing rapidly in agricultural areas in the nineteenth century, legislation was enacted empowering the State or the local communities to restrict the right of the poor to marry. These laws seem to have led to small reductions in over-all fertility, at the cost of higher illegitimacy rates, but they were mostly repealed about 1870 when German unification, economic expansion and emigration began to relieve the earlier crisis.<sup>82</sup>

45. Although the work of Malthus inspired remedies for pauperism, his writings and those of later economists reinforced the prevailing governmental *laissez-faire* approach to population questions in the nineteenth century. Moderate rates of natural increase, accompanied by economic growth and emigration, made this a realistic attitude. However, a number of conditions set the stage for a revival of population policies in the twentieth century. The intensification of nationalism and military insecurity after the First World War together with the marked success with which individuals were able to limit family size in the developed countries—with a consequent drop in birth rates to levels which were considered alarmingly low in a number of countries—encouraged measures favouring higher fertility.

46. By the 1930s declines in fertility had caused gross reproduction rates to fall below unity in such countries as Austria, England and Wales, Luxembourg, Norway, Sweden and Switzerland, and to near unity in France and Germany.<sup>83</sup> These trends stimulated concern in some of these countries about eventual depopulation.<sup>84</sup> The economic depression of the early 1930s accentuated the problems of large families and the disincentives to parenthood. The differing political philosophies and goals of Governments shaped a variety of responses to this situation. In many countries no deliberate population policy was adopted, but where action was taken, it generally aimed at encouraging fertility and increasing the capacity of families to raise children in accordance with higher living standards.

47. In France, official recognition was given to the pro-natalist movement in 1919 by the establishment of a governmental council whose function it was to study questions bearing on fertility and mortality. One element in official policy was legislation prohibiting distribution of birth control propaganda and devices in 1920 and tightening the prohibition of induced abortion in 1923.<sup>85</sup> In 1932, the Government of France took control of the family allowances system—which had been almost exclusively voluntary up to that date, supported only by employers' contributions—and in 1939 introduced the *Code de la Famille* which incorporated and enlarged existing family welfare and pro-natalist measures.<sup>86</sup> Allowances were extended to all economically active persons, and marriage loans, premiums on the birth of a first child and other forms of aid for parents were provided.<sup>87</sup> The policy of Belgium developed along similar lines in this period, though the measures taken were less comprehensive than those of the *Code de la Famille*.<sup>88</sup>

48. The impact of the policies of Belgium and France on fertility appears to have been small in the period before the Second World War, perhaps because of the insecurity and economic problems of the period and the difficulty of allocating sufficient resources to achieve the desired goals.<sup>89</sup> Spengler concluded after an exhaustive study that the family allowance system had failed, up to 1938, to stimulate an increase in the birth rate of France.<sup>90</sup> This was in accord with the views of other scholars, including Glass, who noted that the reason for the failure was twofold: the allowances were inadequate to cover the cost of child care; and the trend towards smaller families altered economic and cultural patterns and, therefore, was not readily reversible.<sup>91</sup>

49. The policy developed in Sweden in the late 1930s was guided by the recommendations of a government commission appointed in 1935 in response to public concern about low fertility and the economic situation of large families. It differed from that in France and Belgium in that it provided benefits in kind rather than in cash, and it aimed at least to keep population constant. Moreover, despite its pro-natalist intent, it allowed sterilization and abortion under certain strictly defined circumstances, and also permitted the use of contraception, in accordance with its commitment to individual freedom, as well as to facilitate the spacing of children and to

<sup>85</sup> Glass, *Population Policies and Movements* . . . (1940), pp. 150, 159.

<sup>91</sup> Glass, *Population Policies and Movements* . . . (1940), pp. 204-209, 370-372.

protect maternal health.<sup>92</sup> Measures affecting fertility which were adopted in other Scandinavian countries in the late 1930s and early 1940s were, as in Sweden, less consistently pro-natalist. They reflect greater support for the growth of public services and a more liberal religious climate than existed in many other European countries.<sup>93</sup>

50. In the Soviet Union, policies affecting fertility followed a less clearly defined course in the 1920s and 1930s. Marxist thought has emphasized the dependence of fertility trends on the development of the social and economic system and the status of women and, in accordance with this view, measures taken by the Soviet Union that affect fertility have not been primarily directed at quantitative demographic goals. However, the policies adopted from 1936 to strengthen marriage, aid child-rearing and restrict the practice of abortion, do appear to have been a response to the sharp drop in fertility that occurred in the early 1930s. This drop was at least partly caused by widespread recourse to induced abortion.<sup>94</sup> The birth rate rose again in the late 1930s, but the Second World War caused severe loss of life and reduced fertility and new pro-natalist measures including an expanded system of family allowances and medals for the mothers of large families were introduced in 1944.<sup>95</sup>

51. In Italy from 1926 and in Germany from 1933, pro-natalist measures were linked with the nationalist and expansionist policies of the governments led by Mussolini and Hitler. A policy of discouraging contraception and prohibiting induced abortion was adopted in both countries and applied with great rigour in Germany.<sup>96</sup> German policy also emphasized financial aid to parents via marriage loans which were cancelled after four births, tax discrimination, grants and services for the support of children. In both countries propaganda and material rewards favoured motherhood as a woman's primary contribution to national strength. In Germany, expansionist, eugenic and racial policies were associated with population policy.<sup>97</sup> German pro-natalist measures do seem to have contributed to higher marriage and fertility rates after 1933, although their influence cannot

readily be separated from the effects of general economic recovery.<sup>98</sup>

52. Spain introduced family allowances, with pro-natalist objectives, in 1938.<sup>99</sup> Japan adopted a range of pro-natalist measures in 1941. The legislation was passed after a period of fertility decline that had dissipated fears of overpopulation and after a decade of expansionist military rule.<sup>100</sup>

### C. Policies affecting fertility in the more developed countries after the Second World War

53. The national conditions that constitute the basis for population policies change, leading to modifications in the policies themselves as well as in the measures designed to support them.<sup>101</sup> In most Western countries there was a recovery of the birth rate in the early post-war period, although the onset, magnitude and duration of the recovery varied from country to country. While the increase in fertility may have served to allay some of the earlier fears of eventual depopulation, it could not be known to what extent the increase was a temporary phenomenon possibly to be followed by a continuation of the downward trend in evidence before the war.<sup>102</sup> In general, where population policies were in effect in the developed countries, in the post-war period, they were intended at least to sustain existing growth rates, if not to increase them.

54. As suggested earlier, in the absence of specific government statements concerning population policy, it is often difficult to deduce from an examination of a country's measures, programmes and laws what its population policy is.<sup>103</sup> This difficulty is particularly apparent in the post-war period, which saw a rapid expansion of social security and welfare legislation—including many measures affecting the family which may have had demographic repercussions, although they were often inspired largely by other than demographic motives. Moreover, the development of progressive social policy led to the adoption by Governments of a series of measures which may have been inconsistent so far as their effects on fertility were concerned. Thus, existing side by side might be certain measures which facilitated access to the means of controlling fertility, and which could be considered anti-natalist in effect and, on the other hand, a wide variety of measures aimed at easing the constraints against child-bearing, and thus pro-natalist. The principle

<sup>102</sup> In fact, by the late 1960s, the birth rate in some of these countries was approaching or had fallen below that of the 1930s. See United Nations, *Demographic Yearbook, 1970* ... (1971), table 13.

<sup>103</sup> Eldridge has written that even "a nation's stated policy is not necessarily an exact statement of its purposes of the moment". Eldridge, "Population policies" (1968), p. 382.

of voluntary parenthood, which various Governments wished to promote, was often supported by liberal abortion laws (which may have initially been designed as health measures),<sup>104</sup> easy access to contraceptives, and sex education in the schools. As is seen in the following discussion, liberalization in these areas appeared even in some of the countries whose governments favoured an increase, or at least stability, of population growth rates. Among the many measures of social policy adopted either with or without the specific intent to influence demographic trends, were provisions for family allowances, preferential employment for heads of families, reduction of taxation on income as family responsibilities increase, aid to mothers (particularly working mothers), and facilities for the care of school-age and pre-school children.<sup>105</sup> In addition, some of the countries granted marriage loans, subsidized public transportation for children below certain ages, underwrote housing and the cost of clothing, enacted measures to protect illegitimate children, and so on.<sup>106</sup>

# 1. POLICIES AND MEASURES IN SELECTED COUNTRIES

55. France probably comes closer to having implemented a comprehensive national policy aimed at increasing fertility than any of the low-fertility countries. The policy was substantially reconstructed in 1939 with the *Code de la Famille* and strengthened in 1945<sup>107</sup> after the birth rate had fallen below 15 per 1,000 population in 1940-1944.<sup>108</sup> The Government explicitly stressed, as the basis for its policies, the demographic crisis and the need to reverse the decline of fertility.<sup>109</sup> In addition to an extensive family allowance scheme, and various other benefits in aid of the family, there were laws banning the sale, advertisement or distribution of contraceptives and restricting abortion.<sup>110</sup> While the distribution of contraceptives was legalized in 1967 in response to public demand, the regulation against commercial advertisement or propaganda for contraceptives remained in force. But to counteract this relaxation of the laws, in 1969 a revised family allowance scheme providing stronger support for large families was approved.<sup>111</sup>

<sup>104</sup> Taeuber, "Policies, programs, and the decline ..." (1964), p. 100.

<sup>105</sup> Vostrikova has stated that society has a responsibility for enabling women to combine motherhood with an active and creative participation in economic, cultural, and scientific pursuits. Vostrikova, "Female fertility and methods ..." (1967), p. 243.

<sup>111</sup> United Nations, *Measures, Policies and Programmes* ... (1972), chap. II, section A-1.

56. As noted above, a government commission of Sweden, prior to the Second World War, recommended that the nation should aim at least at stability of numbers,<sup>112</sup> but it specified the principle of voluntary parenthood as the focus of its policy. Myrdal acknowledged the conflict, but asserted that the dilemma of wanting both increased birth control and increased fertility was one to which solutions would hopefully be found which were in harmony with humanitarian, democratic practice.<sup>113</sup> Swedish policy, while aiming to keep the birth rate from falling, gives precedence to considerations of individual welfare and voluntary parenthood. Among the measures which support both the pro-natalist aims and personal welfare are family allowances, marriage loans and a system of substantial supplementary services and payments in kind, including maternal and child welfare centres, housing grants, free school meals and compulsory maternity leave. At the same time, contraceptive advice as well as contraceptives are readily available, sex education is a standard part of the school curriculum, and abortion and sterilization may be authorized on rather broadly defined grounds.<sup>114</sup>

57. Other developed countries besides France and Sweden have shown awareness of population problems in a number of ways, including the appointment of commissions to study population questions, and the enactment of legislation which may have implicit demographic aims. Some countries have adopted in varying degrees measures similar to those of France and Sweden. In these measures considerations of welfare often take precedence over demographic considerations, even though the general attitude may be pro-natalist. Such, for example, is said to be the case in Denmark, Finland, Norway and the United Kingdom.<sup>115</sup>

58. In the United Kingdom, where the net reproduction rate barely exceeded unity in the early 1950s,<sup>116</sup> it was deemed desirable to keep fertility at a level which would at least be sufficient to prevent population decline. Acceptance of the principle of voluntary planned parenthood implied, on the one hand, that contraceptive devices should be made freely available and, on the other, that social and economic obstacles to parenthood should, as far as possible, be removed.<sup>117</sup> The Royal Commission on Population had recommended that the provision of family planning advice should be among the duties of the National Health Service,<sup>118</sup> and the National Health Service (Family Planning) Act of 1967 made such services

available.<sup>119</sup> While advice on family planning is provided free, a charge is made for prescriptions, except in cases where the physician considers that contraception is required for medical reasons.<sup>120</sup> A liberalized abortion act was also adopted in 1967.<sup>121</sup> While social services of a wide variety have been instituted in the United Kingdom, they have generally been intended as welfare measures rather than to achieve any particular level of fertility, and it cannot be said that a population policy has existed. In recent deliberations on population policy in the United Kingdom, a group of scholars stressed that explicit recognition should be given to demographic considerations in the discussion and formulation of official social and economic policies.<sup>122</sup>

59. Yugoslavia in the post-war period adopted a system of family allowances which could be considered moderately pro-natalist.<sup>123</sup> At the same time, however, abortion legislation was gradually liberalized so as to eventually permit termination of pregnancy on social and economic as well as on medical grounds and family planning services and education in family planning were considerably expanded.<sup>124</sup> In April 1969, the Federal Assembly passed a resolution which recognized the right of parents to decide the number and spacing of their children as a basic human right, the attainment of which would benefit both the parents and society. The resolution noted the obligation of society to provide the knowledge and means for family planning, and the need for a wide participation of educational, health, social security and other institutions to realize the stated goals.<sup>125</sup> Concern was expressed about the high incidence of abortion and measures were proposed to encourage contraception as the preferred means of family planning.<sup>126</sup>

60. According to Berent, moderately high rates of population growth were considered desirable by the Socialist countries of Eastern Europe in the post-war period, and many social measures gave support to large families.<sup>127</sup> It was only in the early and mid-1960s, however, that the need for a premeditated population policy began to be felt, partly in response to fertility declines. Citing a Polish source, Berent indicated that the countries committed to an explicit pro-natalist population policy (by 1970) were Bulgaria, Czechoslovakia, the

German Democratic Republic, Hungary and Romania with Poland and the Soviet Union expected to join this group soon.<sup>128</sup> In response to a United Nations inquiry, the Soviet Union stated that its Government was "interested in increasing the total population of the country, since it goes on the principle that under Socialist economic conditions, population increase represents one of the most important factors in the constant growth of social wealth and prosperity of all members of society".<sup>129</sup>

61. As in Sweden and the United Kingdom, the Governments of most of the Eastern European countries and the Soviet Union aim to mitigate the burden that child-rearing imposes upon parents and to aid individuals to space births in accordance with their wishes and limit their progeny to the number desired. Consequently, measures exist to facilitate birth spacing and limitation on the one hand, while on the other, policies are in force which encourage large families. Where policy concern is specified as relating both to the growth of population and to the well-being or quality of the inhabitants,<sup>130</sup> it is not a simple matter to delineate the population aspects of the policy.<sup>131</sup> A clear demographic policy appears to have been in force in Romania, however, since 1966, the aim being to reverse the course of the birth rate, which had dropped to 14.6 in 1965. Among the steps taken to support this policy were the rescission of the previously liberal measures governing abortion and contraceptives; the levying of taxes against childless persons over 26 years old, whether married or not; and the strengthening of family allowances and related measures.<sup>132</sup>

62. Japan occupies a unique position among the world's developed nations because of the rapidity of the decline in its birth rate in the post-war period. In the decade 1947-1957, the birth rate was halved, from 34.3 to 17.2 per 1,000 population.<sup>133</sup> This precipitous decline was accomplished, not by means of an official Government population control policy, but through measures which made the means of birth limitation legal and available to a population which was already very favourably disposed towards birth control.<sup>134</sup> Although the

See his "O nekotorykh instrumentakh ..." (1968), pp. 64-72.

<sup>128</sup> Berent, "Causes of fertility decline in Eastern Europe ..." (1970), pp. 285-287. David has written that the Socialist countries of Eastern Europe all profess to being pro-natalist. See his *Family Planning and Abortion in the Socialist Countries ...* (1970), p. 12. Kučera, while observing that "Czechoslovakia officially pursues a birth-promoting population policy, proclaimed on numerous occasions by the Government and by the political organs ever since 1945 ...", indicates at the same time that proclamations in themselves are of little avail unless accompanied by measures for attaining the desired ends. See his "Population policy of Czechoslovakia" (1968).

<sup>134</sup> Muramatsu, "Japan" (1966); his "Japan: miracle in East Asia" (1969); and his "Policy measures and social changes ..." (1967).

Japanese Government has never adopted an official anti-natalist policy,<sup>135</sup> high rates of growth in the period following the Second World War gave rise to concern, with the result that efforts of both private and government groups to reduce fertility were permitted beginning in 1951.<sup>136</sup>

63. The first important measure affecting fertility in Japan in the post-war period was the Eugenic Protection Law of 1948 which completely reversed the previous restrictive abortion law. The Law was passed primarily to protect maternal health, which had suffered because of the wide prevalence of illegal abortions, and large numbers of abortions have been performed in accordance with its provisions.<sup>137</sup> In 1952, a programme to promote contraception was instituted with the stated purpose of decreasing the frequency of induced abortion, which was believed to have an adverse effect on health.<sup>138</sup>

64. Commenting on the fact that Japan's total fertility rate and net reproduction rate have been below the minimum for a stationary population since about 1957, Tachi maintains that it is desirable that the net reproduction rate return to one in order to improve the age structure of the population and prevent a rapid fall in the annual labour force increment in the future. To achieve this end, he argues that economic development must be accompanied by certain measures of social development to lighten the financial burden of bringing up children and to improve housing and other living conditions.<sup>139</sup>

65. In the United States, consideration by the Government of the possible desirability of influencing the trend of population through family planning is very recent. At the federal, state and local levels, tax-supported family planning services have until recently been prohibited because of religious and political controversy, and family planning services which existed were carried out mostly by private agencies.<sup>140</sup> In 1963 the United States Congress first authorized support for foreign population programmes; about the same time the Government began to support research in family-planning methods, and funds allocated for this purpose were increased in subsequent years. Legislation enacted in 1967 for the first time emphasized the provision of family planning services, particularly for low-income persons, a trend which has since continued.<sup>141</sup> The President's Committee on Population and Family Planning, established in 1968, urged the expansion of domestic family planning pro-

grammes to make information and services available by 1973 to all women on a voluntary basis.<sup>142</sup>

66. By 1970 the President and Congress had established the Commission on Population Growth and the American Future to provide information and education regarding the implications of population growth. In 1971, resolutions were introduced in the House of Representatives and the United States Senate expressing the view that it should be the policy of the United States to encourage stabilization of the population by voluntary means. By the end of 1971 the United States had adopted no policy which called for the limitation of population growth, though it was increasingly providing services designed to permit parents to achieve the family size they desired by eliminating unwanted births.<sup>143</sup>

67. Canada, a country which has traditionally felt a need for a larger population, has pursued a selective immigration policy in the post-war years. Prohibitions against the advertisement, exhibition, sale or distribution of contraceptives were set out in 1927 legislation, which, however, was rarely invoked.<sup>144</sup> In 1969 the Food and Drug Act was amended to authorize the advertisement of contraceptives under specified conditions,<sup>145</sup> and in 1970 the Minister of Health and Welfare announced a federal government programme involving research, training and public information in family planning. It was the government's belief that the programme, which was to emphasize the right of individuals to exercise free choice in the practice of family planning, would have beneficial effects in reducing the incidence of unwanted births, child neglect and other abuses.<sup>146</sup>

## 2. IMPACT OF MEASURES AFFECTING FERTILITY

68. The decline of fertility in the nineteenth and twentieth centuries in the now industrialized countries is believed to have been closely related to basic changes in economic and social conditions which occurred as part of the process of modernization of these societies. Among the crucial economic and social factors likely to have affected fertility were urbanization, industrialization, social mobility, level of education, rising costs of education and changing family functions and structure (see the discussion in chapter IV, section D). The evidence concerning the relation of such factors as these to fertility levels is far from precise, being drawn for the most part from qualitative studies which provided the basis for various hypotheses.

69. Among the factors believed to have had a bearing on fertility levels were various kinds of economic and social legislation, but no effort has been made to assess the role of such legislative measures in the historical

<sup>135</sup> On one occasion, however, a high Government official—the Minister of Health—linked family planning in Japan to the population problem. See Kunii, "Postwar movement and programme..." (1967), p. 95.

<sup>146</sup> Canada, Department of National Health and Welfare, *News Release* (1971).

decline of fertility. Some of these measures, most notably child labour and compulsory education laws, probably had an anti-natalist effect, while existing side by side with them may have been other measures, such as those outlawing abortion or the sale and advertising of contraceptives, which, although they were often primarily moral in intent, may have had a pro-natalist effect. It is the purpose of the present section to consider what evidence exists of the effect on fertility of various measures which the Governments of developed countries have implemented in the post-war period. While some of these measures were enacted with the intent of influencing fertility, others represented the responses of Governments to a great range of economic, social and cultural imperatives.

70. A recent United Nations study, which has attempted a systematic analysis of social, economic, demographic and other measures affecting fertility, classified such measures into four categories:<sup>147</sup>

(a) Measures related to the family, such as family-allowance programmes, systems of taxation on income, aid to maternity and rewards to mothers;

(b) Measures of social reform, including compulsory education and child-labour laws, as well as social-security programmes;

(c) Laws relating to abortion, contraception and sterilization;

(d) Marriage and divorce laws relating to age at marriage, polygamy, divorce and remarriage.

Measures belonging to the first category could be expected to be mainly pro-natalist in effect, those in the second category, anti-natalist, while those in the third and fourth categories might be either, depending upon their specific nature.

71. There do not appear to have been any studies that have established conclusively the relationship between fertility and the various measures that Governments have implemented which may conceivably influence it.<sup>148</sup> Nor does the literature reveal any systematic attempt to analyse the effects of a mixture of measures, some tending to have a positive impact on fertility, while others have a negative one. The studies which have been made pertain to the influence of certain measures, apparently without taking into account the effect that other important elements in the complex of provisions may have.

(a) *Effects of measures tending to increase fertility*

72. There are various types of allowances and presumably such effect upon fertility as any one might have would depend, *inter alia*, upon the measure itself and what it added to the family living standards or way of life.<sup>149</sup> It is considered by many French demographers that the family allowance system had a positive effect

upon fertility in France during the years following the Second World War.<sup>150</sup> Many of the shortcomings of the earlier system appear to have been corrected when the benefits were enlarged in 1946. Thus, Febvay and others found that the scheme did have some success in raising fertility levels after the end of the war, partly because of the comprehensiveness of the programme which gave support to the family in a variety of ways.<sup>151</sup> But the scheme appears not to have yielded the results desired by the French policy-makers. As Sauvy emphasized many years later, the French family allowance system did not produce more large families, its influence being felt mainly with regard to the second and third child.<sup>152</sup>

73. Questiaux doubted that there is a causal relationship between fertility and family allowances. He noted, among other things, that the post-war birth rate rose not only in France, but also in countries where there were no similar measures in aid of the family, and presented data to show that, although the 1965 French and Italian birth rates were nearly identical, the net national income from family benefits was over 40 per cent higher in France.<sup>153</sup> Eldridge, who cautioned against such comparisons in view of the treacherous nature of crude birth rates and the complexity of the subject matter, tended to agree that evidence as to the influence of family allowances on French fertility is far from conclusive.<sup>154</sup>

74. Gille analysed birth rates for young married couples in Norway and Sweden in relation to family allowances in those countries and concluded that, while the possibility that the allowances had had a positive effect upon Swedish fertility after the Second World War could not be excluded, such was apparently not the case in Norway. It will be recalled that the Government of Sweden aimed at a stable, if not increasing rate of population growth. Gille offered as partial explanation the Swedish programme's greater comprehensiveness and the payment of allowances beginning with the first child rather than with the second, as in Norway.<sup>155</sup>

75. In Hungary, a measure was introduced on 1 January 1967 entitling gainfully occupied women to a children's allowance until the child reaches the age of three years, provided that the woman remains at home. It was reported that more than two thirds of employed women having a child in 1967 availed themselves of this allowance. The percentage of first births occurring in 1967 was significantly higher than in earlier years, suggesting that the new measure influenced women to bring forward

<sup>147</sup> United Nations, *Measures, Policies and Programmes ...* (1972), chap. I. For another classification see Hoogenboom, "Population policy and law" (1971).

<sup>148</sup> United Nations, *Measures, Policies and Programmes ...* (1972), chap. I. On the difficulties of isolating effects of particular measures, see Larson, "Summary of findings ..." (1971), pp. 451-452.

<sup>149</sup> *Ibid.* Tax deductions for dependants may be expected to have effects similar to those of family allowances except that individuals may be less aware of the benefits accruing to larger families through tax provisions than in the case of direct allowances.

<sup>150</sup> Girard determined from the results of a 1949 survey that 97 per cent of the respondents were of the opinion that the family-allowance scheme had been an influential agent in the post-war recovery of the French birth rate. Girard, "Le problème démographique ..." (1950), p. 338.

<sup>151</sup> Febvay, "L'évolution de la natalité ..." (1959), p. 58. See also Doublet, "Réflexions sur dix années ..." (1958).

<sup>152</sup> Sauvy, *De Malthus à Mao Tsé-toung ...* (1958), p. 217; and his "Réflexions sur la contribution ..." (1958), pp. 508-509. It is not considered that the allowances created a desire for an additional child, but made it possible for couples to have the number of children normally desired prior to the enlargement of the scheme.

<sup>153</sup> Questiaux, "Family allowances in France" (1968), p. 87.

<sup>154</sup> Eldridge, *Population Policies: a Survey ...* (1954), pp. 76-77.

<sup>155</sup> Gille, "Scandinavian family allowances ..." (1954), pp. 188-189.

the birth of their first child. While the opinion was expressed that these women would probably have more children than women who put off the birth of the first child,<sup>156</sup> it was considered too early to draw conclusions about the long-term effects of the child's care allowance on fertility.<sup>157</sup>

76. Lynes considered that in Great Britain (United Kingdom) allowances were effective as social policy, but not as demographic policy.<sup>158</sup> Heer and Bryden found no relationship between allowances and fertility in the USSR, but considered that the allowances may have been too small to have generated a rise in fertility.<sup>159</sup> Kučera offered a similar explanation for the failure of allowances to encourage higher levels of fertility in Czechoslovakia; they did not provide sufficient assistance.<sup>160</sup>

77. Two small surveys conducted in South Africa and the Netherlands to determine attitudes towards family allowances and to establish their possible influence upon family-size preferences gave conflicting results. Among a sample of married white women under age 50 in Johannesburg, South Africa, the granting of "adequate" family allowances would have increased family-size preferences on the average by approximately one child.<sup>161</sup> Among a group of adults in Leiden, the Netherlands, on the other hand, about 70 per cent thought that an increase in family allowances would have had no effect upon family size.<sup>162</sup>

78. There appears to be no simple answer as to whether and how children's allowances, at various degrees of adequacy, affect family size. In Whitney's view, European plans had not paid enough to cover the cost of child-rearing, and the possibility could therefore not be excluded that there is a payment level at which allowances would stimulate births. Moreover, he held that the influence of allowances can be obscured by other forces within society that bear upon fertility. He concluded, as did Eldridge, that available evidence did not support the contention that such allowances promote fertility.<sup>163</sup>

<sup>163</sup> Whitney, "Fertility trends and children's ..." (1968), pp. 129-133; Eldridge, *Population Policies: a Survey ...* (1954), p. 76. Freedman found that the relevant literature concerning whether such pro-natalist government measures as allowances can increase fertility is inconclusive. See his "The sociology of human fertility ..." (1961-62), p. 63.

79. Simon argued, on the other hand, that incentives to raise fertility, such as bonuses, child payments and tax deductions for children, necessarily have some positive effect, "because some people must be at the margin of indifference about more or fewer children than they have ..." and the incentive payments may be the decisive factor. He acknowledged, however, that useful data on this subject are practically non-existent.<sup>164</sup>

80. The effects of restrictive abortion legislation on fertility depend partly on the extent to which other forms of birth control are practised. It is evident that the abrupt cessation of a liberal abortion policy can cause a sharp increase in the birth rate. Romania is the much cited example: the change in law, announced abruptly in October 1966, was followed by crude birth rates of 27.4, 26.3, 23.3 and 21.1 in each year from 1967 to 1970 respectively; the 1965 and 1966 rates were 14.6 and 14.3. Only a minor increase in the birth rate followed the restrictive legislation in Bulgaria in 1967: the 1967 rate was 15.0, compared with a crude birth rate of 16.9 in 1968, 17.0 in 1969 and 16.3 in 1970.<sup>165</sup> However, Bulgaria did not ban contraception, but provided increased counselling and aid in conception prevention; nor did it implement other repressive measures in the interest of higher fertility, as Romania did.<sup>166</sup>

81. It has been noted, however, that rescission of legislation against abortion brings about only a temporary increase in the birth rate; Acsádi observed this in respect of the temporary reversal of Hungary's liberal abortion law in 1953.<sup>167</sup> The post-1966 fertility rates in Romania cited above would tend to bear this out, though there are only a few years for which the new trend can be observed, and short-term behaviour of crude birth rates must be interpreted with caution.

82. Little is known of the influence of restrictive legislation relative to contraceptives upon fertility. In France, where contraception is believed to be practised with a high degree of effectiveness after desired family size has been attained, a study has estimated the effects on fertility of the availability of a 100 per cent effective contraceptive. The results suggest that the crude birth rate would be reduced over the short term by from approximately 2 to 22 per cent, this wide range being due to uncertainty regarding several important variables, including the degree of effectiveness with which contraception is currently practised, and the proportion of couples who would adopt the completely effective contraceptive.<sup>168</sup>

<sup>164</sup> Simon, "The effect of income ..." (1969), p. 340. The results of a preliminary study done by the author in the United States showed a substantial relationship between the amount paid by different states to foster parents and the proportion of state-aided children in foster homes.

(b) *Effects of measures tending to decrease fertility*

83. Various students of conditions in Eastern Europe and the USSR have observed that levels of fertility may be depressed by the rising status of women.<sup>169</sup> However, not enough is known of the ways in which measures to increase the status of women may influence family size. This constitutes an important gap in knowledge of conditions that may be causally related to fertility change.

84. An indicator frequently used by analysts to measure the status of women is employment outside the home, although other indicators may also be used. It is generally acknowledged that this indicator is negatively associated with fertility levels.<sup>170</sup> One of the explanations of this relationship is as follows: from the economic point of view, the greater the discrimination against women in employment, the lower will be the wife's opportunity costs of time spent upon the caring and rearing of children, the lower her incentive for employment outside the home, the higher her fertility, and vice versa.<sup>171</sup> While the employment of women outside the home is associated with fertility levels, it is also related to many other conditions within the society, such as higher education.<sup>172</sup> There is also an element of selectivity involved, in that low-parity women are more likely to seek employment opportunities outside the home.<sup>173</sup>

85. In developed countries practising family planning, laws prohibiting child labour and providing for compulsory education, if enforced, could be expected to have a depressing effect on fertility since they increase the costs which families must bear for the upbringing of children and at the same time deprive the families of income obtained through their employment.<sup>174</sup> However, such a hypothesis was not clearly substantiated by the results of a regression analysis of the relationship between fertility levels and the number of years of compulsory education in a study carried out by Friedlander and Silver. On the other hand, the same authors found quantitative support for the hypothesis that the existence

of social security legislation, which presumably would cause parents to be less dependent upon their children, is associated with lower fertility.<sup>175</sup>

86. Most of the existing knowledge of the demographic impact of a liberalized abortion policy derives from the experiences of Eastern European countries and Japan. The quantitative effects on fertility of such policies are difficult to measure precisely, however, for a number of reasons. An important source of error may be the under-reporting of the number of abortions performed. In Japan in 1955, for example, the completeness of reporting of induced abortions was estimated to be between 52 and 77 per cent.<sup>176</sup> One reason for the unreliability of abortion figures is that private practitioners who perform the operation may not always register it. On the other hand, figures for some countries include abortions performed on visitors from abroad.<sup>177</sup> A further difficulty in measuring the effects of liberal abortion policies on fertility is the lack of knowledge regarding the volume of abortions which would previously have been performed illegally, but which are performed legally under liberalized legislation.<sup>178</sup>

87. In attempting to assess the effects of abortion on fertility, the relationship between the number of abortions and the number of live births must be interpreted critically. Mehlman observed that increased incidence of abortion is associated with increased pregnancy rates.<sup>179</sup> This is because the length of gestation (during which conception cannot occur) is shorter, and because the period of sterility is also shorter following induced abortion than following full-term pregnancy. Thus, according to Potter, an equal number of abortions and live births does not indicate that the birth rate is being halved because "100 artificially terminated pregnancies account for less marriage duration than do 100 pregnancies allowed to go to term".<sup>180</sup> He calculated that, when combined with contraception which is 90 per cent effective, the situation is different: "100 induced abortions now absorb 5,400 months of marriage duration, equivalent to 82 live births in the case of no lactation, and 72 live births in the case of prolonged lactation".<sup>181</sup> According to Keyfitz's calculations, with unprotected intercourse it takes nearly three abortions to prevent one birth, while 1.14 abortions suffice to avert one birth if a 95 per cent efficient contraceptive is used.<sup>182</sup>

88. In addition to the immediate effect of an induced abortion—i.e., the prevention of a live birth after conception has occurred—other effects have been observed. It was found in Japan that the incidence of "secondary

<sup>182</sup> Keyfitz, "How birth control . . ." (1971), p. 112.

sterility and habitual abortion and miscarriage" rose after induced abortion.<sup>183</sup> However, Mehlan's data for the German Democratic Republic disclosed that sterility as well as other complications were lower following legally induced abortions than criminal abortions.<sup>184</sup>

89. The difficulties of precise measurement of the effect of liberalized abortion policies notwithstanding, it has been observed that "birth rates have generally declined in countries in which abortion has been legalized and there seems no doubt that abortion played a role in this reduction."<sup>185</sup> Analyses have suggested that these reductions in fertility in Japan and the countries of Eastern Europe were not related to changes in age structure or proportions married, but to changes in marital fertility and, hence, to birth control. Brackett found that, in the Eastern European countries, the birth rate decreased by 40 per cent in the decade or so following liberalization of the abortion laws.<sup>186</sup> According to Mehlan, the fertility decline was not initiated by the changes in the laws, but rather accelerated by them.<sup>187</sup>

90. The Japanese crude birth rate declined precipitously from 33.0 in 1949 (the year following the establishment of the Eugenic Protection Law) to 17.2 in 1960.<sup>188</sup> It was estimated that in 1955 alone, abortions to Japanese women prevented between 1,379,000 and 2,054,000 births; the number of live births actually registered was 1,731,000.<sup>189</sup> According to Muramatsu, induced abortion was the major factor in the decline of Japanese fertility. It has been estimated that, aside from the effect of the postponement of marriage, at least 70 per cent of the birth rate decrease in the post-war period up to 1955 could be attributed to induced abortion, and the remaining 30 per cent to contraception and sterilization.<sup>190</sup> The family planning programme initiated by the Government in 1952 had only a limited effect upon fertility.<sup>191</sup>

91. Citing data for Bulgaria, Czechoslovakia and Hungary, Tietze and Lewit observed that where abortion laws are permissive, legal abortions rise sharply.<sup>192</sup> As to the demographic significance for the Eastern European region, Tietze concluded in another study that the legalization of abortion has had a depressing effect upon the birth rate in most of these countries. He cited as evidence the fact that marked declines in the birth rate had occurred between the early 1950s and early 1960s in all of the countries of Eastern Europe where abortion had been legalized (except the USSR), whereas during the

same period Western European countries and those Eastern European countries which had not legalized abortion experienced either moderate increases in fertility or only slight declines. He noted, moreover, that these two groups of countries were sufficiently similar with respect to patterns of population structure, relative changes in *per capita* income and other indicators of social well-being to have had similar natality trends.<sup>193</sup>

92. Regarding the USSR, it has been noted that the number of registered abortions increased markedly following legalization of abortion in November 1955. An increase of 82 per cent occurred between 1955 and 1956, and the number of abortions continued to increase each year up to 1965, though at a slower rate. In 1966 the number of abortions performed was lower than in 1965. Available data show that the ratio of abortions to live births increased from 1.6 in 1960 to between 2.5 and 3.0 in 1965.<sup>194</sup> Findings from a survey in the Armenian Soviet Socialist Republic (USSR) disclosed that, among the workers, abortion is the principal method of birth control. Among a sample of women undergoing abortion, it was found that the average number of abortions per woman was 4.7. According to Artunyan, this high abortion rate was due not to the failure of contraceptives, but to an insufficient propagation of contraceptive methods as a means of controlling family size.<sup>195</sup>

93. The interpretation of the effect of liberalized abortion laws on fertility trends must also take into account the possible changes in contraceptive practice which such laws may engender. Some authors hold that the legalization of abortion reduces the practice of contraception, since abortion requires only one decision and is based upon certainty rather than supposition. Others maintain that the legalization of abortion leads to increased contraceptive practice. This may be because the population becomes more birth-control conscious and motivated, and also because Governments often attempt to educate the public to use effective contraception rather than abortion as a means of family limitation.

94. Frederiksen and Brackett hold that in some Eastern European countries, particularly Hungary, but also Bulgaria, legalized abortion brought about a reduction in contraceptive practice because pregnancy rates increased sharply along with legal abortion rates, while total fertility declined only slightly.<sup>196</sup> It has been pointed out, however, that before the legalization of abortion in Hungary, the number of illegal abortions performed was very high, and it is therefore difficult to establish the effects of legal induced abortions on fertility. Hungarian experts have concluded that, while the legal abortion system has probably retarded the effective practice of contraception, there are indications that more modern

and effective methods are spreading among younger couples.<sup>197</sup>

95. In Japan, contraceptive practice appears to have increased steadily in the years following the liberalization of abortion. Based on a series of surveys, the proportion of contraceptors among wives under 50 years of age rose from 19.5 in 1950 to 51.9 in 1965.<sup>198</sup> Studies by Aoki and Muramatsu, for example, showed that in Japan between 1955 and 1965 the role played by contraception in preventing births increased, whereas that of induced abortion diminished.<sup>199</sup> Diggory and his colleagues hold that the experience of both Japan and Eastern Europe "has shown that improvements in contraceptive practice can and do occur concurrently with easy access to abortion".<sup>200</sup>

96. After reviewing the experience of Sweden, Japan and the Eastern European countries, Frederiksen and Brackett concluded that the effect of the legalization of abortion on patterns of contraception varies from country to country. In countries where contraception is already widely practised, a proportion of the population may, as a result of the ease of obtaining legal abortions, practise it less effectively, thus increasing abortion rates without substantially affecting birth rates. Conversely, where abortion is widespread, the introduction of contraception may contribute to declines in both abortion rates and fertility rates.<sup>201</sup>

97. The literature does not show that any effort has been made to examine differences in national laws governing marriage, divorce and separation in the developed countries to determine if they are related to variations in fertility. Eldridge observed that "where differences are not striking, it seems reasonable to suppose that other factors have a more profound effect on the average age at marriage and perhaps also on the rate of marriage dissolution than do legal ones". A change in the minimum age at marriage is not likely to have much effect on fertility in countries where large proportions of the population marry later than the minimum age established by law.<sup>202</sup>

98. The effect of divorce on fertility is unclear, since it depends on prevailing customs concerning remarriage and on the relative strength of different influences. In some cases childless marriages which result in divorce may be replaced by marriages which produce children, and some persons who otherwise would have remained single are, because of divorce, able to marry and bear children. On the other hand, many divorced persons may

not remarry. It has been pointed out that, while liberal divorce laws may increase the disposition to marry, they also reduce the stability of marriage.<sup>203</sup>

#### D. Policies affecting fertility in developing countries

99. In the developed Western countries, the transition from high to low fertility occurred in the absence of birth limitation policies, and sometimes in spite of pro-natalist policies.<sup>204</sup> In the vast majority of today's developing countries, however, mortality declines that were effected by improved medical care and public health measures, especially after the Second World War, have not as yet been followed by a commensurate downward course in the birth rate. Rather, in most of these countries, fertility has generally remained stable at a high level and, with the consequent broadening of the gap between birth and death rates, the population has been growing at unprecedented rates. The problems engendered by this so-called "population explosion" have stimulated Governments to formulate policies which aim to curb excess population growth by lowering fertility levels.

##### 1. REASONS FOR MODERATING POPULATION GROWTH

100. The retarding effect of rapid population growth on economic and social development has led increasing numbers of government officials and scholars to conclude that the regulation of such growth is not only plausible, but imperative.<sup>205</sup> Most nations which have embarked upon a policy aimed at attaining a lower level of fertility have emphasized such reasons as the necessity of reducing population growth to a rate that is more compatible with accelerated progress in economic and social development.<sup>206</sup> In a review of conditions and policies in 67 developing countries, Nortman observed that the "ultimate objective of such [population] policies is a higher standard of living, to which Governments, as a general principle, have always been committed". But she noted that now, as opposed to the past, nations are less willing to tolerate abysmally low standards of living.<sup>207</sup> In writing about the role of a fertility policy in economic development, Coale and Hoover have maintained that a reduction of fertility immediately reduces the burden of dependency; and that fewer consumers (especially children) permit greater flexibility in the mobilization of resources for economic growth, facilitating the use of savings and tax

<sup>207</sup> Nortman, "Population and family planning programs ..." (1970), p. 4.

receipts in such a way as to raise national output, as less is required for consumer needs and social overhead. They cautioned that "to postpone the reduction of fertility [in low-income countries] is to forgo the opportunity for a more rapid rise in immediate well-being, and to shrink the potential growth in incomes *per capita* for the indefinite future".<sup>208</sup>

101. A number of Governments have specified particular problems which would be mitigated by slower population growth. Thus, some have mentioned the need to reduce the rate at which the labour force increases in order to lighten the task of providing new employment opportunities and to alleviate unemployment and underemployment.<sup>209</sup> In addition, the benefits of slower population growth for meeting development requirements in such areas as education,<sup>210</sup> housing<sup>211</sup> and social welfare services<sup>212</sup> have been mentioned by some Governments.

102. Other reasons often mentioned as being important in the decision of Governments to implement a policy of fertility regulation have been the promotion of human dignity, the well-being of the family in general, and the health of mothers and children.<sup>213</sup> The health factor in particular has been stressed, the rationale being that fewer births at longer intervals will enhance the health of mothers and children and alleviate some of the problems of raising and caring for children.<sup>214</sup> The adverse effects upon health of widespread illegal abortion have also been a consideration in some countries.<sup>215</sup>

103. Because Governments of developing countries must allocate their scarce resources among a large number of projects, some knowledge of the economic benefits to be derived from investment in population programmes, as compared with other developmental schemes, is an important factor in policy-making. One approach in

this sphere is the cost-benefit analysis developed by economists, which, when applied to population, attempts to estimate the value of births averted by population programmes in relation to their cost.

104. Much of the discussion in this field revolves around Enke's estimates that the value of a birth prevented in a developing country is one to two times the annual *per capita* income of that country, and his assertion that 1 per cent of total development budgets spent on reducing births could be as effective in raising output per person as the other 99 per cent of the budget.<sup>216</sup> Enke, as well as others, suggests that such a saving has further policy implications, namely in the awarding of monetary incentives by Governments to couples for abstaining from child-bearing.<sup>217</sup>

105. Various writers have taken issue, either with Enke's basic approach, or with specific arguments or assumptions. Leibenstein argued that deficiencies in the formulation of such models tend to invalidate them, and maintained that there were biases in the analysis which led to the expectation of unduly favourable results for birth control programmes. Moreover, he presented a model based on other assumptions which gave results opposite to those of Enke's.<sup>218</sup> Krueger and Sjaastad criticized Enke's model mainly for its reliance on economic factors as the sole criteria of welfare, thus omitting the non-economic desires of individuals.<sup>219</sup> Demeny agreed with the theory and even with the order of magnitude of Enke's estimates of the value of a prevented birth, but considered that Enke erred in exaggerating the effectiveness of bonus payments in raising *per capita* income.<sup>220</sup> Reviewing the debate over the findings of cost-benefit analysis, Ohlin concluded that while "precise estimates are out of the question", investments in family planning are likely to result in "spectacular benefits".<sup>221</sup> Other economists have presented a case for investments to reduce fertility without attempting to quantify the economic value of a prevented birth.<sup>222</sup>

<sup>222</sup> See, particularly, Coale and Hoover, *Population Growth and Economic Development* ... (1958), part V.

## 2. THEORETICAL BASIS FOR POLICIES AND MEASURES TO REDUCE FERTILITY

106. To meet with some degree of success, a country's policies, programmes and measures for controlling fertility must be based on an understanding of the complex interrelationships between population trends and economic and social conditions and cultural patterns.<sup>223</sup> Unfortunately, knowledge of these interrelationships is still grossly deficient. The information which does exist regarding the relation between fertility reduction and other societal factors pertains, for the most part, to present-day industrialized countries, and the conclusions drawn may have only limited applicability for the high-fertility developing regions. Moreover, even these data have given rise to divergent interpretations on the part of scholars. Various theories relating to factors affecting fertility have been discussed extensively in chapter IV, sections D and E. A brief summary of some of the major factors believed to influence fertility trends, together with a discussion of how theories about fertility change affect the formulation of policies and measures to bring about such change, is presented in this section.

107. It is widely held that the secular decline in fertility in the now industrialized, low-fertility countries was the result of a variety of factors intricately interrelated with socio-economic development, or of what is generally referred to as the modernization of society.<sup>224</sup> Coale finds support for this view in the fact that all modernized societies have low fertility, though he points out that no single indicator of modernization is itself manifestly related to controlled fertility.<sup>225</sup>

108. Although there is a consensus that fertility declines once the forces of modernization are under way, different authors emphasize different factors in the development process as being of particular relevance. It has been observed, for example, that a secular decline of mortality generally occurs before large numbers of individuals make efforts to control fertility.<sup>226</sup> Freedman holds as a speculative hypothesis that "family planning is unlikely to be widely adopted in any country until there has been a significant mortality decline and until there has been enough social and economic development to lessen dependence on local and familial institutions and make

smaller families more rewarding than larger families".<sup>227</sup> The spread of education and literacy, particularly among women, is believed by some to be fundamental to changes in human reproductive behaviour. Improvements in the status of women in general have been stressed as having marked influence upon fertility,<sup>228</sup> but, as mentioned above, the precise nature of this association has not been established.

109. While many writers agree that fertility will decrease only in a *milieu* in which some measure of economic and social development is evident, there has not yet evolved any systematic theory as to how such development affects the individual motives that produce fertility change.<sup>229</sup> Some scholars consider that reproductive behaviour is strongly influenced by the cultural and social *milieu* and that, hence, changes in attitudes, values and motivation as regards reproduction necessarily involve prior or concurrent social change.<sup>230</sup>

110. The available evidence shows that there still exist substantial differences in desired family size between the populations of industrialized and developing countries, and thus it is unlikely that the provision of contraceptives and education in their use would alone be sufficient to achieve low fertility levels.<sup>231</sup> In addition, many scholars hold the opinion that the motivation required to attain even the moderate family size, for which preference is sometimes expressed, is largely lacking among these populations.<sup>232</sup> As knowledge of factors influencing motivation is crucial to understanding behavioural change in this sphere, many studies have examined values and

<sup>231</sup> See the discussion in chapter IV, section E. Tabbarah, after a review of existing surveys, estimated that in most of Asia and North Africa the majority of married couples desired between four and eight children, while in Africa south of the Sahara the range was still higher. See his "Toward a theory of demographic development" (1971), pp. 262-263. To improve knowledge of the relationship of economic factors to reproductive behaviour, Easterlin proposed a theoretical framework based on the theory of household choice, expanded to include "taste" factors. According to his formulation, reproductive behaviour is determined by a balancing of preferences relating to children, goods, leisure etc., on the one hand, and various constraints, such as the price of child care, on the other. Easterlin, "Towards a socio-economic theory ..." (1969), pp. 138, 150.

<sup>232</sup> See chapter IV, section E.

<sup>223</sup> Boyarsky, for example, has proposed that economic, social and demographic analysis covering long periods of time would be necessary for a comprehension of the factors relevant to the formulation of population policy. Boyarsky *et al.*, *Kurs demografii* (1967), p. 37.

<sup>224</sup> A summary and review of the literature is provided by Freedman, "The sociology of human fertility ..." (1961-1962); see also his "Fertility—statement by the moderator" (1966), pp. 36-49; Coale, "Factors associated with the development ..." (1967), pp. 207-208; Davis, "The theory of change ..." (1965), p. 78; and Gyllenswärd, "Extinction or explosion ..." (1967), particularly p. 209.

<sup>225</sup> Coale, "The voluntary control ..." (1967), p. 168.

<sup>226</sup> For a survey of relevant literature, see Freedman, "The sociology of human fertility ..." (1961-1962), pp. 67-68.

goals with respect to family size in relation to various economic and social characteristics of the population surveyed.<sup>233</sup>

111. Since knowledge of the conditions required to bring about a decline in fertility is so inadequate, opinions of scholars differ in regard to the degree of economic and social development necessary before a family planning programme can achieve much success, although few writers on the subject maintain that initiation of family planning programmes should await an advanced stage of economic development.

112. Macura holds that it is untenable to attempt modifications of reproductive behaviour separately from modifications in the social and economic structure, in marital patterns, and in education and mortality, for it is the combination of these that influences rationality in reproductive behaviour.<sup>234</sup> According to Tabbarah, family planning programmes would be effective only at a stage in a country's demographic development where two conditions are met: (1) a large proportion of couples wish to limit their births (and this is not at present the case in many developing countries), and (2) these couples lack adequate birth control knowledge and/or supplies and facilities.<sup>235</sup> In Raina's view, the national family planning programme of India can be effective only if it is implemented within the context of substantial economic and social change. He holds that, in addition to the popularization of birth control, the essential tasks are raising standards of living, improving public health and ameliorating problems of unemployment, aging, illiteracy, and the like.<sup>236</sup> Glass summarized his position as follows: "Direct programmes for spreading the use of birth control are . . . only a small part of the action in which developing societies will require to engage. The largest part will have to consist of planned economic and social development. . .".<sup>237</sup>

113. Sauvy has written that a purely economic solution cannot suffice, and a demographic solution requires preliminary, or at least simultaneous, economic development. Both solutions must therefore be considered.<sup>238</sup> According to Urlanis, birth rates in developing countries "will be reduced to a certain extent as a result of women's participation in production, a higher level of culture and the development of industry", but he added that "a demog-

raphic policy specifically aimed at smaller families may be of great significance".<sup>239</sup> Guzevaty observed that "the overwhelming majority of newly liberated States are planning their economic development, but this cannot be achieved unless population factors are taken into account and efforts are made to influence them so as to ensure a better combination of population growth and economic progress".<sup>240</sup>

114. Some proponents of family planning have put less emphasis on modernization and development as prerequisites for fertility decline, holding that the vast majority of high-fertility groups are desirous of limiting family size and will do so if given the knowledge and means. A leading adherent of this view is Bogue, who believes that essential social change has already taken place even in the more remote rural areas of developing countries and that these populations are now receptive to the idea of limiting births.<sup>241</sup> Stycos has also expressed optimism concerning the success of family planning programmes, pointing to the desire for moderate-sized families that exists in less developed countries and the fact that nowhere have such programmes encountered active opposition on the part of the target population.<sup>242</sup> Notestein, Kirk and Segal have argued that there is no need to rely on the gradual changes in society that occur with modernization to bring about eventual fertility decline, and that while social inertia is an obstacle to the rapid spread of family planning, it is not an insuperable obstacle.<sup>243</sup> Berelson, while acknowledging that development or modernization programmes in general will have a favourable impact on the spread of contraception, urges that "direct effort on contraception is worth while in itself, as a contribution to the speeding-up of this element in the over-all development equation".<sup>244</sup>

115. The notion thus persists that national family planning programmes are likely to facilitate such change as will encourage at least some segments of the population voluntarily to regulate fertility. And it is due to the force of this opinion that a steadily increasing number of Governments are adopting such programmes—usually in conjunction with intensified development efforts—as the principal instrument of a policy that advocates lower fertility.

116. Several authors have disagreed with the prevailing optimism concerning the possible contribution of family

<sup>233</sup> See, for example, Blake, "Demographic science . . ." (1965), p. 65; and her "Population policy for Americans . . ." (1969), p. 524; and Freedman, Baumert and Bolte, "Expected family size . . ." (1959), pp. 144-150.

<sup>234</sup> Macura, "International aspects . . ." (1965), p. 77. See also United Nations, *Social Change and Social Development Policy . . .* (1970), pp. 287-288; International Bank for Reconstruction and Development, *Partners in Development . . .* (1969), p. 198.

<sup>235</sup> Tabbarah, "Toward a theory of demographic development" (1971), pp. 274-276; see also his "Birth control and population policy" (1964). A basic question which warrants research is: at what point in the development process of a given country would the introduction of a family planning programme be most propitious? Lapham, "Population policies in the Maghreb" (1971), p. 43.

<sup>236</sup> Raina, "Possible effects of public policy . . ." (1967).

<sup>237</sup> Glass, "Population growth and population policy" (1965), p. 23.

<sup>238</sup> Sauvy, *De Malthus à Mao Tsé-toung* (1958), pp. 289-290.

<sup>239</sup> Urlanis, "John Graunt's offspring . . ." (1967), p. 7.

<sup>240</sup> Guzevaty, "Population problems in . . ." (1966), p. 58.

<sup>241</sup> Bogue, "The demographic breakthrough . . ." (1964), p. 450.

<sup>242</sup> Stycos, "Population and family-planning . . ." (1964), p. 174. In assessing the probable contribution of family-planning programmes in fertility decline, Coale sees as favourable factors the desire on the part of populations of developing countries for smaller families than those actually attained, and the inclusion in the programmes of provisions for influencing attitudes and motivation. Coale, "The voluntary control . . ." (1967), p. 169.

<sup>243</sup> Notestein, Kirk and Segal, "The problem of population control" (1969), pp. 144-145 and 147. In another article, Notestein called attention to certain conditions favourable to fertility decline which now exist in developing countries, among them the spread of national policies favouring family planning, public interest in limiting child-bearing and the recent improvements in contraceptive technology. Notestein, "The population crisis . . ." (1967), p. 170.

<sup>244</sup> Berelson, "National family planning programs . . ." (1969) p. 369.

planning programmes. According to Podyachikh, birth control is unlikely to be adopted in the developing countries until they achieve a certain measure of economic and social advancement. Moreover, family planning programmes are unnecessary, inasmuch as a fertility decline will occur once the major economic and social problems have been mastered.<sup>245</sup> Valentei has written that attempts to reduce fertility in a relatively short period by "artificial" means (i.e., family planning programmes) are doomed to failure. In his view, the achievement of the desired goal, i.e., lower fertility, requires that the Government undertake concerted action for economic and social development.<sup>246</sup>

117. Kuznets views efforts to reduce the birth rate as having only limited potential for solving the economic growth problems of disadvantaged areas, although he is not opposed to such efforts as long as they do not deflect resources from other essential development programmes. He considers that a high rate of population growth is only one, and not necessarily the most important, of many problems facing developing nations, and if the other problems are not solved, a slowing down of population growth will have only a moderate effect, in the next decade or two, on *per capita* product. The solution of the economic growth problems lies rather in policies directed at changing economic, political and social institutions—changes which will at the same time result in more moderate population growth.<sup>247</sup>

118. Blake has argued that neither the "economic development" approach nor the "family planning" approach is adequate when taken alone or in combination. What is needed are policies directly related to family roles which affect the motivational framework of reproduction by providing satisfying alternatives to child-bearing.<sup>248</sup> In view of the recognition of the need for changing family-size norms and increasing individual motivation for family limitation, elaborate systems of communication designed, *inter alia*, for this purpose, are often

<sup>245</sup> Podyachikh, "Impact of demographic policy ..." (1968), pp. 240, 242, 250.

<sup>246</sup> Valentei, *Teoria i politika narodonaseleniâ* ... (1967), pp. 177-183. A similar view has been expressed by Burnashev in "Aktualnye voprosy rosta naseleniâ ..." (1970). Taking into account the relationship between modernization and fertility, some Governments have attempted to accelerate modernization in crucial economic and social spheres in what appears to be an aspect of population policy. Concerning such policies in Algeria, see Lapham, "Population policies in the Maghreb" (1971), pp. 40-42.

<sup>247</sup> Kuznets, "Population and economic growth" (1967), pp. 189-190. See also Raulet, "Family planning and population control ..." (1970). It has been suggested, however, that Kuznets has underestimated the importance of rapid population growth as a deterrent to economic development. See Organisation for Economic Co-operation and Development, *Population Programmes and Economic and Social Development* (1970), pp. 23-24.

<sup>248</sup> Blake, "Demographic science ..." (1965), pp. 67-68. See also her "Reproductive motivation ..." (1971). Davis, "Population policy ..." (1967); and his "Will family planning solve ..." (1968). Lorimer has also emphasized the fundamental role of personal motivation in fertility regulation, but he believed that government programmes could influence attitudes in this area. Lorimer, "Issues of population policy" (1945), p. 179.

integrated into family planning programmes.<sup>249</sup> Moreover, it is being increasingly emphasized that the techniques of communication for motivation in family planning must be tailored to the culture of the people.<sup>250</sup>

### 3. PREVALENCE OF NATIONAL POLICIES DESIGNED TO REDUCE FERTILITY

119. Once the desirability of reducing population growth was accepted by some of the developing countries, fertility became the focus of attention, since it is the only component of national population growth whose regulation to achieve desired ends is both practicable and acceptable. Emigration on the scale necessary to alleviate the problem of rapid growth is not feasible, except in the case of countries with very small populations, and continued mortality declines are universally desired. A number of countries therefore took the decision to pursue a fertility-reduction policy, and some Governments provided for its implementation within the context of a comprehensive national economic and social development scheme. (See chapter XVI, section E.)

120. The Governments of India and Pakistan established national family planning programmes for the purpose of reducing fertility levels in the early and mid-1950s. These programmes were gradually expanded, and by the 1960s they were operating with greatly increased resources, widespread publicity and various improvements geared to achieve a more satisfactory public response.<sup>251</sup> Information from a variety of sources suggests that China adopted a policy and supporting measures to control births in the mid-1950s, with a view to reducing the rate of population growth, although the policy appears to have been temporarily abandoned after a short time, and then later resumed. Official statements explaining the purpose of the policy have at different times emphasized control of population growth rates, health reasons, and the emancipation of women. The birth-control measures have been pursued with varying degrees of intensity since adoption of the policy.<sup>252</sup>

<sup>249</sup> According to Coale, the fact that many family planning programmes utilize modern techniques of communication to influence attitudes and motivation was one reason for considering that they may achieve success. Coale, "The voluntary control ..." (1967), p. 169. Davis, however, considered that "mass-communication" techniques could not solve the motivation problem and that basic changes in social structure were required. See his "Population policy ..." (1967), particularly p. 733. For a review of communications aspects of family-planning programmes of countries in the ECAFE region, see United Nations, Economic Commission for Asia and the Far East, *Communications in Family Planning* ... (1968), pp. 11-17.

<sup>250</sup> For example, see United Nations, Economic Commission for Asia and the Far East, *Communications in Family Planning* ... (1968), p. 11; United Nations, *Measures, Policies and Programmes* ... (1972), chap. V.

<sup>251</sup> See the summary of provisions for family planning in successive development plans of India and Pakistan in chapter XVI, section E. See also United Nations, Economic Commission for Asia and the Far East, *Administrative Aspects of Family Planning* ... (1966), pp. 7 and 9.

<sup>252</sup> Chen, "China's birth control action programme" (1970); Organski and Organski, *Population and World Power* (1961), pp. 215-222; Han, "Family planning in China" (1971); Tchang, Mao and Hou, "La loi de population en régime socialiste ..." (1959). See also China, *Proposals of the Eighth National Congress* ...

(Continued on next page)

121. Iran and the Republic of Korea adopted a policy of regulating births in the early 1960s, and a few years later three other Asian countries—Ceylon, Malaysia and Singapore—and Turkey, which has both Asian and European influences, took similar action.<sup>253</sup> Thus, nations of Asia, where problems of development were among the most critical, played a leading role in shaping world opinion as to the merits of regulating births as an aid to national and individual well-being.<sup>254</sup> By 1966 eight countries of other regions had undertaken a similar policy and made provisions for implementing it. In addition to Barbados, Fiji and Jamaica, these countries included five in Africa—Kenya, Mauritius, Morocco, Tunisia and the United Arab Republic.<sup>255</sup>

122. By the end of 1966, the regulation of fertility had become official policy in at least sixteen developing countries, one half of which were in Asia. These countries contained about 31 per cent of the 1966 population of the world's developing regions. But if China, about whose policy there was some question, is added, the figure would be about 59 per cent.<sup>256</sup>

123. Important increases occurred in the late 1960s in the number of countries adopting a policy to lower the birth rate. This trend was undoubtedly influenced by the international concern for problems of development and by the deliberations within the United Nations and its specialized agencies during the years 1962 to 1966.<sup>257</sup> The dialogue not only generated increased awareness of the interrelationship between the population factor and economic and social development, but also helped to crystallize opinion relevant to policy formulation.<sup>258</sup>

124. As a result of the increased momentum, around the middle of 1970 thirty-three countries could be said to have adopted official policies aimed at facilitating the spread of birth control on a voluntary basis.<sup>259</sup> The

(Footnote 252 continued)

(1956), p. 99; Freeberne, "Birth control in China" (1964); Thompson and Lewis, *Population Problems* (1965), pp. 556-561. In an interview with Premier Chou En-lai in 1964, the journalist and author Edgar Snow was told that the Government of China hoped to see its annual rate of population growth fall below 2 per cent by 1970. Snow, "Population care and control" (1971), p. 8.

<sup>253</sup> Government statements regarding family planning extracted from the development plans or other official sources of these countries are contained in United Nations, "Governmental policy statements . . ." (1970).

<sup>254</sup> See the discussion in United Nations, Economic Commission for Asia and the Far East, *The Asian Population Conference, 1963* (1964), particularly pp. 52, 54-55.

<sup>255</sup> See the government statements reproduced in United Nations, "Government policy statements . . ." (1970).

<sup>256</sup> Thompson and Lewis have indicated that, because of the sudden changes in China's population policy, "it is necessary to make a very significant reservation as to the proportion of the population in the under-developed countries . . . that will be consistently assisted by their governments . . ." in controlling population growth. Thompson and Lewis, *Population Problems* (1965), p. 562.

<sup>257</sup> See United Nations, *The World Population Situation in 1970* (1971), chap. 7.

<sup>258</sup> These views are reflected in United Nations, *Inquiry among Governments . . .* (1964); ———, Economic Commission for Asia and the Far East, *The Asian Population Conference, 1963* (1964), pp. 29-35.

<sup>259</sup> Such policies also existed in Taiwan and in the French Overseas Departments. See United Nations, "Governmental policy statements . . ." (1970), p. 17.

combined population of these countries amounted to about three fourths of the total in developing regions.<sup>260</sup> Included are eight countries in Africa—Botswana, Egypt, Ghana, Kenya, Mauritius, Morocco, Nigeria and Tunisia; fourteen in Asia—Afghanistan, Ceylon, China, India, Indonesia, Iran, the Republic of Korea, Malaysia, Nepal, Pakistan, the Philippines, Singapore, Thailand and Turkey; ten in Latin America—Barbados, Chile, Colombia, Costa Rica, the Dominican Republic, Honduras, Jamaica, Nicaragua, Panama and Trinidad and Tobago; and Fiji in Oceania.<sup>261</sup>

125. The regulation of fertility, however, is as yet far from commonplace in most of these countries, as the announcement of a policy merely implies that the government is committed to making available the knowledge and means whereby individuals who so desire may control the number and spacing of births.<sup>262</sup> In actuality, family planning facilities are often unevenly distributed throughout a country so that not all segments of the population have equal access to them.<sup>263</sup> On the other hand, family planning programmes have been carried out on a fairly large scale and with government support in some countries where no official declaration of policy has been made.<sup>264</sup> All in all, despite the rapid growth in the number of countries adopting policies aimed at reducing birth rates, the vast majority of the population of developing regions still lacks the knowledge and means for birth control.

#### 4. THE NATIONAL FAMILY PLANNING PROGRAMME

126. Governments which have adopted a policy of bringing about a voluntary reduction of births have typically established a national family planning programme. Such programmes have also been adopted or supported by some Governments which do not have a formal population-limitation policy. Family-planning programmes are relatively new and still in the process of evolving, and are intended to fulfil a number of requirements simultaneously. These include inducing behavioural change on a voluntary basis; providing individuals with the means of achieving desired family size; improving the health and well-being of family members, particularly mothers and young children; and facilitating a reduction of population growth rates. Some of these aims are overlapping, or even conflicting in certain respects. The main reasons why family planning is usually the first step taken

<sup>260</sup> If China, whose policy at particular times has been somewhat uncertain, is not included, the figure drops to about 47 per cent.

<sup>261</sup> It should be noted that the Government of Ceylon later shifted from a policy of reducing the birth rate to a position of providing support for family planning programmes in the interest of maternal and child health. See Nortman, "Population and family planning programs . . ." (1971), p. 20.

<sup>262</sup> United Nations, *Measures, Policies and Programmes . . .* (1972), chap. II, sections A-2(a) and A-3. Although the programmes in these countries are based upon the principle of voluntary parenthood, abortion is still restricted in most of them, so that in the case of contraceptive failure the principle may not find support.

<sup>263</sup> United Nations, *1967 Report on the World Social Situation* (1969), p. 19.

<sup>264</sup> *Ibid.*, pp. 19-20; United Nations, *Measures, Policies and Programmes . . .* (1972), chap. II, section A-2(b).

in a population-control policy have been suggested by Berelson. He indicates that family planning is likely to be acceptable from a political standpoint because it can be perceived as a health measure, because it is voluntary, and because it promotes personal freedom by enabling couples to have the number of children desired. In addition, it is a gradual effort, and can be relatively inexpensive.<sup>265</sup> Family planning programmes are not, as many have stressed, considered by the Governments as alternatives to economic and social development.<sup>266</sup>

127. It is worth noting that in contributing to the improved health of women, family planning programmes may exert certain influences favourable to higher fertility. By emphasizing birth spacing, they may help to alleviate sub-fecundity and secondary sterility and to lower the incidence of prematurity. Pathological conditions that afflict the reproductive organs, such as venereal disease, may also be detected and treated when patients seek assistance with fertility problems.<sup>267</sup>

#### (a) Some salient features

128. The national family planning programmes are often elaborate schemes, designed to obtain maximum use of available resources for spreading knowledge about the value and means of family-size limitation and birth spacing, and for providing at little or no cost birth-limitation services and supplies. Although the programmes differ in organization, scope and provisions from country to country, depending, *inter alia*, upon the level of economic and social development and the size of the country, some or all of the following activities are involved: (a) acquisition and maintenance of buildings and equipment; (b) staffing of clinics and administrative offices and the recruitment and training of medical, para-medical, clerical, administrative and other personnel; (c) the setting of targets as to the number and characteristics of persons to be reached by the programme, and their recruitment; (d) provision of medical, social and related services pertaining to the adoption and use of contraceptives or other methods of birth control; (e) selection of contraceptive method(s) to be used, and provision for their supply and distribution; (f) the development of effective communications, including the use of mass media, to supply information and influence motivations; (g) allotment of financial and other resources at local, regional and national levels; (h) record-keeping, for example of

the characteristics of clients and the services rendered to them, as well as of the performance of staff; (i) processing, publishing and feeding back the recorded information to those staff who require it; and (j) evaluation of the performance of staff, of the machinery, and of the demographic impact of the programme. Such an endeavour involves a number of government departments, e.g., health, social welfare, education, and finance, but authority rests more often with the Ministry of Health. Some Governments have established a separate family-planning agency.<sup>268</sup> Normally, and particularly in the larger countries, responsibilities for implementing the programme are carried out at local, regional and national levels, with the smaller units reporting to the next larger unit.<sup>269</sup>

129. National family planning programmes generally promote the use of contraceptives as the most suitable means of regulating fertility. None of the countries that has implemented such a programme has on its statutes a law restricting their availability or use. On the contrary, the intention of such programmes is to have all women at the risk of pregnancy choose the means that will enable them to control conception.<sup>270</sup> It is therefore desirable that a number of methods be offered, and the trend in fact has been towards a multimethod approach, although a few programmes still rely heavily upon a single method.<sup>271</sup> The means of family limitation offered to acceptors of family-planning programmes—i.e., contraception, sterilization and, in rare instances, abortion—may also be available and legal in the private sectors of countries with family planning programmes, as well as in countries which do not have such programmes.

130. Generally, induced abortion is illegal in the developing countries,<sup>272</sup> and few countries with family planning programmes have included induced abortion among the approved methods of spacing and limiting births. In some, however, abortion within the programme is tolerated, if not encouraged.<sup>273</sup> Tunisia has enacted legislation that permits abortion for women within three months after conception provided they have at least

<sup>265</sup> Berelson, "Beyond family planning" (1969), p. 1.

five living children, or if their health would be threatened by the continuation of the pregnancy.<sup>274</sup> Morocco has a similar legal provision.<sup>275</sup> China (except Taiwan) permits abortion for humanitarian reasons, provided that the period of gestation is three months or less and the woman did not have an abortion within the previous twelve months.<sup>276</sup> Liberalized abortion laws in aid of fertility regulation were enacted in Singapore in 1969,<sup>277</sup> and in India in 1971.<sup>278</sup> China (Taiwan) has considered, but not enacted legislation to permit a liberalization of abortion laws. Officials in some of these countries have expressed reservations as to the adequacy of medical resources to meet the health demand that more lenient abortion laws would create.<sup>279</sup>

131. Sterilization as an instrument of family limitation is still controversial in many parts of the world. It is one of the methods of birth control employed in some measure by national family planning programmes for example, in Ceylon, China (Taiwan), Hong Kong, India, Malaysia, Nepal, Pakistan, the Republic of Korea, Thailand and Tunisia;<sup>280</sup> and it may also be available outside, or in the absence of, a family planning programme.

132. The laws permitting sterilizations vary. In some of the countries, it is stipulated that a woman or couple must have had a certain number of children, or that a man must be within a certain age category or have had at least a specified number of children, while in others there are no such qualifications.<sup>281</sup> However, Presser found, on the basis of an extensive survey, that sterilization for birth-control purposes has so far been practised only on a very limited scale except in India, through the national family planning programme, and in Puerto Rico, which does not have a national family planning programme.<sup>282</sup>

#### (b) Policy considerations affecting programme impact

133. The measure of success achieved by national family planning programmes is affected by policy considerations relating to most of the various activities involved in these programmes, which have been enumerated earlier. For example, a decision to promote a programme of birth spacing rather than of the limitation of completed family size may influence efficiency of contraceptive

practice, and, hence, of programme impact. Potter has found that couples desiring two children, for example, will practice contraception more effectively if they have the two children that they want than if they have one child or no children. He suggested that as long as spacing is the purpose of contraception, its effectiveness is low, possibly because "a substantial minority of couples" take chances.<sup>283</sup>

134. The contraceptive method chosen as the primary one to be offered in a programme is another policy measure that can influence contraceptive practice and its efficiency. The methods vary in respect to effectiveness, and rates at which couples continue to apply a contraceptive also appear to depend upon the type of method, among other things.<sup>284</sup> It has been shown, for example, that the continuation rate for the pill is considerably lower than that for intra-uterine contraception.<sup>285</sup> In a study which compared the effectiveness of oral and intra-uterine contraception, however, Tietze concluded that the former is much more effective in preventing pregnancy than the intra-uterine device (IUD). Analysing data on over 477,000 woman-months of IUD use and on 270,000 cycles of oral contraceptive medication, he found that IUD users had a pregnancy rate of two to three per 100 women during the first year of use, while the users of oral contraceptives had a pregnancy rate per 1,000 women per year which varied from 0.7 to 1.4, depending upon the type of medication.<sup>286</sup>

135. A decision to emphasize voluntary sterilization, rather than contraception in family planning programmes can also influence the birth-rate.<sup>287</sup> Narain has shown that in India the average age of women at sterilization is higher than at adoption of the IUD, for example. He found that 62.8 per cent of Indian couples with four or more living children adopted sterilization, while 55.7 per cent adopted the IUD. Also, when sterilization was the method of choice, the average age of females was 32.2, whereas initial adoption of the IUD occurred when the woman was, on the average, 29.4 years old.<sup>288</sup> However, the IUD obviously has lower use-effectiveness and continuation rates.

136. Provisions as to the number of living children, age at sterilization, and choice of spouse for the operation are additional important policy decisions. Both wide prevalence and early timing appear to be requirements if voluntary sterilization is to have a notable impact. Citing Puerto Rico, Presser points out that, both in the late 1940s, when only small percentages of women had been

<sup>287</sup> Presser pointed out that estimates of births prevented by sterilization in Puerto Rico far exceed estimates of births prevented elsewhere by use of the IUD or oral contraceptives. See her "Voluntary sterilization ..." (1970), p. 17.

<sup>288</sup> Narain, "India: the family planning ..." (1968), p. 3.

sterilized, and in 1953-1954, when sterilization had reached significant proportions but generally occurred after a relatively large number of pregnancies, the demographic impact was minimal. By 1965, however, the role of sterilization as a control agent had achieved greater importance; at that time about one third of women aged 20 to 49 years who had ever been married were found to have been sterilized, and to have had an average of 3.9 births. The median age at sterilization was about 26 years. On the other hand, in India and Pakistan the operation is usually performed at higher age and parity. Various studies conducted in these countries suggest that the wife is generally in her early thirties at the time of sterilization, which occurs on average when she already has about four or five living children. Presser poses these differences as being among the important reasons for the greater impact of sterilization in Puerto Rico than in the other countries.<sup>289</sup>

137. It has been argued that family planning programmes are likely to be more successful if they are combined with maternal and child health services. A number of reasons have been advanced for this position. In the first place, such a system ensures contact with the most fertile segment of the population and makes it possible to reach the women at a time when they are highly receptive to family planning, during the post-partum period. Moreover, acceptance of family planning is believed to be closely related to reductions in foetal, infant and childhood mortality which can be achieved through the improved health care provided to mothers and children. Finally, the personnel and facilities needed for family planning work are similar to those required for maternal and child care services and it is more convenient for the pregnant woman with children to visit one place for medical care and family planning services than several different ones.<sup>290</sup>

### (c) *Impact of the national family planning programme*

138. The statistical tools and data for measuring, with a reasonable degree of accuracy, the effects of family planning programmes on fertility levels in the community or nation as a whole are as yet insufficiently developed.<sup>291</sup> As Kirk and Hauser among others, have pointed out, there are no satisfactory methods at present for measuring small, short-term fertility changes in most developing countries, where vital statistics are generally of unsatisfactory quality. Moreover, in those few countries where

statistical data of fairly good quality confirm that a fertility decline is under way, such a trend was already evident before the family planning programme was introduced and may be more attributable to economic and social advancement than to the family planning programme. In view of the difficulties of assessing what would have happened in the absence of a programme, no precise measurement of the effects of the programme seem possible.<sup>292</sup> Pointing out that cause and effect can never be proved in the social field with the certainty that applies in the exact sciences, Wolfers urged the adoption of a "principle of greatest probability", according to which a specific programme operating in the midst of other changes of a non-specific nature may be credited with a large share of the specific effects.<sup>293</sup>

139. In the absence of reliable data and techniques by which to assess the effects upon fertility of the family-planning programmes, a wide range of opinions has emerged regarding the extent to which they have achieved the goals set for them. A few writers such as Bogue maintain that the programmes have demonstrated their effectiveness as a means of reducing birth-rates in developing countries and that, with expeditious efforts on the part of administrators, the control of rapid population growth will soon be accomplished.<sup>294</sup>

140. At the other extreme are those who hold that national family-planning programmes cannot sufficiently curb excess population growth, as the programmes usually emphasize the right of the parents to decide the number and spacing of children, and the collective wishes and resultant behaviour of individuals may not add up to what is considered to be the common good. Davis argues that merely making contraception available to all will not reduce fertility to desired levels in the absence of changes in family size desires. Motivation for smaller families depends on changes in family structure, in the position of women and in sexual mores—all of which are outside the scope of family planning programmes.<sup>295</sup> According to the same author, "it is difficult to prove that present population policies have even speeded up a lowering of the birth rate . . .".<sup>296</sup> Blake also has found family planning programmes to be ineffective in lowering fertility among the masses in developing countries because of their superficiality and the fact that they do not aim to deflect people from familial roles, thus passing up the chance to reduce motivation for small families.<sup>297</sup>

141. Few writers, however, subscribe fully to either of these opposing views. Borrie has criticized what he

<sup>289</sup> Presser, "Voluntary sterilization . . ." (1970), pp. 11, 13, and 16; and her "The role of sterilization . . ." (1969). In one study of tubal sterilization in Pakistan, Roberts and his colleagues found that the women were on average 29 years old at the time of sterilization. Roberts *et al.*, "A post-operative study . . ." (1964), p. 98. On the other hand, studies for India and Pakistan which pertained to male sterilizations showed that the average age of the wife was somewhat higher. These findings suggested to Presser that in the case of female sterilizations, the woman was likely to be younger than the wife of a sterilized man at the time of his sterilization. Presser, "Voluntary sterilization . . ." (1970), p. 13.

<sup>290</sup> World Health Organization, *The Organization and Administration . . .* (1969), pp. 18-22; Taylor and Berelson, "Comprehensive family planning . . ." (1971), pp. 22-23.

<sup>291</sup> While new techniques have recently been developed, for example, for measuring the relative effectiveness of different contraceptives, many difficulties remain. Raulet, "Family planning and population control . . ." (1970), p. 227.

<sup>292</sup> Kirk, "Natality in the developing countries . . ." (1969), p. 90; and his "Prospects for reducing natality . . ." (1967), pp. 57-58; Hauser, "Non-family planning methods . . ." (1969), p. 59; and his "Family-planning and . . ." (1967), pp. 405-406. See also Borrie, *The Growth and Control of World Population* (1970), p. 276.

<sup>293</sup> Wolfers, "The means of measurement . . ." (1969), p. 451.

<sup>294</sup> Bogue expects that, owing mainly to family-planning activities, the world population crisis will have been largely solved by the year 2000. See his "The end of the population explosion" (1967), p. 11. A more cautious optimism is expressed by Berelson in "National family planning . . ." (1969), pp. 367-374.

<sup>295</sup> Davis, "Population policy . . ." (1967), pp. 732-734 and his "Will family planning solve the population problem?" (1968).

<sup>296</sup> Davis, "Population policy . . ." (1967), p. 734.

<sup>297</sup> Blake, "Demographic science . . ." (1965), pp. 67-69.

considers Bogue's overly optimistic faith in the capacity of contraceptive technology and crash birth-control programmes to bring population growth under control in the near future in the absence of social and economic change, and given the generally desired family size of around four children. At the same time, Borrie believes that Davis has overstated the case against family planning programmes, which, according to Borrie, aim to reduce growth rates "as a necessary first step in the process of social and economic change".<sup>298</sup>

142. Other writers have commented on the problems of determining the impact of family planning programmes in specific situations. Mauldin has offered the hypothesis that when a secular decline in fertility is not under way, any decrease immediately after initiation of a programme may be attributed to the programme.<sup>299</sup> A programme may also give impetus to a fertility decline which is already in progress.<sup>300</sup> This seems to have occurred in Taiwan and probably also in Hong Kong.<sup>301</sup> Writing of the Taiwan programme, Potter and his associates concluded that birth control practice was increasing before the programme had begun, and birth control outside of the IUD programme had been increasing since. They asserted with some confidence that the several hundred thousand participants in the Taiwan programme had dramatically increased their birth control practice and decreased their fertility since entering the programme.<sup>302</sup> To what extent this would have occurred in the absence of the IUD programme, however, could not be established. Path analysis has been used by Hermalin and others as a means of isolating the effect on declining fertility in Taiwan of the family planning programme from that of changes in some social and economic factors taken to represent modernization. The results were interpreted as showing that the programme had an additional significant effect beyond that of the social and economic factors.<sup>303</sup>

<sup>298</sup> Borrie, *The Growth and Control of World Population* (1970), pp. 273-274.

<sup>299</sup> Mauldin, "Births averted by ..." (1968), p. 2.

<sup>300</sup> Stycos, "Population and family-planning ..." (1964), pp. 170-171.

<sup>301</sup> Concerning Taiwan, see, for example, Chow, "Evaluation of a family planning ..." (1968), p. 307. Freedman and Adlakha considered it plausible that the substantial real decline in marital fertility which took place in Hong Kong between 1965 and 1966 could be accounted for by the introduction of the IUD through the family planning programme. See their "Recent fertility declines ..." (1968), pp. 189-192. Muramatsu has speculated that the Government's efforts in diffusing knowledge of family planning probably speeded the fall of fertility in Japan. Muramatsu, "Policy measures and social changes ..." (1967), p. 98. It was considered that by 1968 the family planning programme had contributed very little to fertility decline in Tunisia. Vallin and Lapham, "Place du planning familial dans l'évolution ..." (1969).

<sup>302</sup> Potter, Freedman and Chow, "Taiwan's family planning program" (1968), pp. 852-853.

<sup>303</sup> Hermalin, "An area analysis ..." (1970), p. 350. See also Freedman *et al.*, "The family planning ..." (1969), pp. 329-339; Freedman and Takeshita, *Family Planning in Taiwan ...* (1969), pp. 308-310. A similar conclusion regarding the impact of the family planning programme in Taiwan was reached by Schultz, who, in addition, attempted to evaluate the effects of different programme inputs, defined in terms of man-months of employment of different types of medical and health workers. Schultz, *Effectiveness of Family Planning ...* (1969), particularly pp. 31, 34-35.

143. In order to evaluate the impact of family planning programmes, various scholars have devised measures of the number of births averted by the programmes. These estimates vary considerably owing to different methods of calculation, as well as for different methods of birth control.

144. Rather widely differing estimates have been obtained concerning births averted by the IUD. Based on experience in Taiwan, Chow estimated that six IUD insertions would prevent one live birth per year.<sup>304</sup> Lee and Isbister estimated that in the Korean programme 1.1-1.9 births would eventually be prevented by each IUD insertion, the range of estimates reflecting different assumptions concerning the ages of women at the time of insertion, and the duration of use of the IUD before its removal.<sup>305</sup> Using a more refined technique and taking account of the fact that some women who adopt the IUD are substituting it for other birth-control methods, Potter obtained lower estimates of births averted than did Chow or Lee and Isbister. His estimate of 0.94 births averted per first IUD insertion was reduced to 0.64 or 0.43, depending on assumptions concerning the methods for which the IUD was substituted.<sup>306</sup>

145. Using an approach somewhat similar to that of Potter's, and based on a study of post-partum women in Singapore, Wolfers calculated that one IUD insertion averted approximately 0.1 births in the first year, 0.23 in the second year and 0.2 in the third year. When account was taken of the fact that women accepting the IUD might have adopted contraception even in the absence of the programme, these estimates were slightly reduced.<sup>307</sup> Chang and his colleagues evaluated the demographic impact of an IUD programme in Taiwan by comparing the fertility decline for IUD acceptors with that for a group of non-acceptors matched with respect to age, education and other characteristics. The resulting estimates of the net effect of the IUD, while lower than in some other studies, were still found to be substantial. The authors concluded that the decline in the fertility rate of the acceptors was about 80 per cent as compared with an average decline of only 48 per cent among the "matches".<sup>308</sup> It must be emphasized that estimates derived from different studies are not comparable because of the different methods and assumptions used.

146. Various scholars have calculated the effects of hypothetical sterilization targets on the birth-rate in India, with widely differing results. Gopalaswami argued, for example, that acceptance of sterilization by 5 per 1,000 population annually could reduce the Indian birth-rate by 12 points in a decade.<sup>309</sup> Others, such as Agar-

<sup>304</sup> Chow, "Evaluation of a family planning ..." (1967), p. 269.

<sup>305</sup> Lee and Isbister, "The impact of birth control ..." (1966), p. 748.

<sup>306</sup> Potter, "Estimating births averted ..." (1969), pp. 428-432.

<sup>307</sup> Wolfers, "The demographic effect ..." (1969), p. 140.

<sup>308</sup> Chang, Liu and Chow, "Study by matching ..." (1969), pp. 140-143. The study covered persons accepting the IUD for the first time in 1964, 1965 and 1966, the cut-off date for the period of observation being 31 December 1967.

<sup>309</sup> Gopalaswami, "Family planning ..." (1962), pp. 77-78. For other estimates of the effect of a large-scale sterilization campaign, see Sarma, "Demographic effects ..." (1963).

wala, however, held such estimates to be overly optimistic. His own calculations suggested a more likely decline of only about 5.5 points in ten years.<sup>310</sup>

147. Very few estimates have been made of births averted by oral contraceptives and by conventional contraceptives, partly no doubt because of the difficulties in establishing use-continuation rates for these methods of birth-control.<sup>311</sup> Potter has attempted to make such estimates, however, using a theoretical model incorporating various assumptions regarding the conditions and circumstances of oral contraceptive use. Depending on such assumptions as whether the pill is used alone, in place of another contraceptive, or as a supplement to another contraceptive, births averted by one segment of contraception (that is, for the period of usage between initiation and interruption) were found to vary from 0.09 to 0.74.<sup>312</sup>

148. As mentioned above, abortion has only rarely been included as an approved method of birth limitation in family planning programmes of developing countries, and in the few countries having such provisions there are as yet no studies of the impact on the birth-rate. However, some theoretical studies have recently been developed to estimate the effect of abortions in reducing births (see section C above).

149. Ridker, after reviewing the programmes of several countries, concluded: "While there can be no doubt that current family planning programmes will have some significant impact, it is very unlikely that by themselves they can achieve anything like what has come to be considered an acceptable target. Methods with a sharper cutting edge must be added."<sup>313</sup> These findings are generally supported in the writings of several scholars, including Hauser, who stated: "To achieve fertility control, present family planning programmes must recognize the role of abortion as supplementary to conception control; must adopt the objective of ... [inducing] couples to desire a replacement level number of children; and may have to consider the abandonment of voluntarism in favour of sanctions and incentives."<sup>314</sup>

## 5. NON-FAMILY PLANNING MEASURES TO REDUCE FERTILITY

150. Because of the magnitude of the problems posed by rapid population growth and the relatively slow rate at which fertility is declining in response to family plan-

<sup>310</sup> Agarwala, "Sterilization as a population ..." (1964), p. 1,091; Agarwala, "The arithmetic of sterilization in India" (1966), p. 213. See also Haynes *et al.*, "A study on the effectiveness of sterilizations ..." (1969).

<sup>311</sup> Concerning estimates of continuation rates for the oral pill, see Jones and Mauldin, "Use of oral contraceptives ..." (1967), p. 5. An attempt has been made in Pakistan to develop methods for estimating "couple years of protection", taking into account the extent of use of conventional contraceptives, IUD's, vasectomies and tubal ligations. See Mauldin, "Births averted by ..." (1968), p. 6.

<sup>312</sup> Potter, "Births averted by ..." (1970), pp. 251, 269.

<sup>313</sup> Ridker, "Desired family size and the efficacy ..." (1969), p. 279. The author expressed the view that more efforts are required to increase motivation for small families, and suggested monetary incentives as a possibility.

<sup>314</sup> Hauser, "Non-family planning methods ..." (1969), p. 66.

ning programmes alone, a broader approach to the question of population control has been advocated by some writers on the subject and a variety of proposals for limiting population growth have been made which go "beyond family planning".<sup>315</sup> Among such proposals have been: "higher legal age at marriage; greater educational, recreational, and employment opportunities for women; bonus payments for periods of non-pregnancy; tax incentives not to have children; tax penalties for too many children; societal tolerance of deviant sexual behavior such as homosexuality; compulsory sterilization after a certain number of children; and so on".<sup>316</sup> As can be seen, these proposals vary as to financial costs, the degree of coercion involved, the extent to which they are compatible with existing cultural patterns, the feasibility of putting them into practice, their potential for success in terms of lowering fertility etc. A few of the more moderate proposals, some of which have been adopted or are under consideration in some countries, are discussed below.

151. Among laws relating to marriage, divorce and remarriage that have implications for fertility conditions and trends, the most important are those governing legal age of consent to marriage and the conditions in which parents may permit marriage at ages below that of legal consent.<sup>317</sup>

152. Several countries have raised the minimum marriageable age in the interest of reducing population growth rates. The Government of China had raised the minimum ages to 18 for females and 20 for males in 1950.<sup>318</sup> In Pakistan, the minimum age at marriage for girls was advanced from 14 to 16 years in 1961.<sup>319</sup> The Government of India in 1949, advanced the marriageable age for girls from 14 to 15.<sup>320</sup> Other countries such as Ghana have also indicated their intention of considering modifications in policy regarding age at marriage.<sup>321</sup> Among the legal reforms enacted in Tunisia as part of its population programme which began in 1964 were the prohibition of polygamy and the advancement of marriage age to past 20 for men and 17 for women.<sup>322</sup> In a recommendation

<sup>315</sup> For a summary, see Berelson, "Beyond family planning" (1969).

<sup>316</sup> Nortman, "Population and family planning problems ..." (1970), p. 4. For a discussion of specific proposals see, for example, Blake, "Reproductive motivation ..." (1971), pp. 219-220; Robinson and Horlacher, "Population growth ..." (1971), pp. 31-32.

<sup>317</sup> A discussion is provided in Eldridge, *Population Policies: a Survey* ... (1954), pp. 119-121; and United Nations, *Measures, Policies and Programmes* ... (1972), chap. I, section D-1.

<sup>318</sup> Chen, "China's birth control action programme ..." (1970), p. 153; Huang, "Birth control education campaigns" (1971), pp. 25-26; Chen, "Birth control, late marriage ..." (1957). Around 1970, the "recommended" minimum age at marriage was 25 for women and 28-30 for men. Although these recommendations had not been embodied in law, society exerted pressure for conformity. See Snow, "Population care and control" (1971), p. 6; Han, "Family planning in China" (1971), p. 21.

<sup>319</sup> Pakistan, *The Muslim Family Laws Ordinance* ... (1961), p. 4.

<sup>320</sup> Sastry, *The Child Marriage Restraint Act* ... (1949), p. 5.

<sup>321</sup> See Ghana, *Population Planning for National Progress and Prosperity* ... (1969), p. 21.

<sup>322</sup> Daly, "The basic aspects of population programmes in Tunisia" (1970), p. 48.

to the Government of Mauritius regarding means of reducing fertility in that country, Titmuss and Abel-Smith proposed, *inter alia*, a marriageable age of 18 for girls; the age at that time (1960) was 15.<sup>323</sup>

153. In view of the difficulties of enforcing laws relating to age at marriage, passage of legislation altering the minimum marriage age is not necessarily an indication that changes will take place.<sup>324</sup> Students of Indian demography have been particularly interested in the possible effect upon fertility of measures raising the minimum marriageable age in that country, a step which the Government has taken as part of its policy to lower fertility rates.<sup>325</sup> Although there is wide disagreement in India and elsewhere as to the quantitative effects of such measures, there nevertheless appears to be some accord that age at marriage does influence fertility levels where contraception is not widely or effectively practised.<sup>326</sup>

154. There is no evidence that nations pursuing a policy aimed at lowering fertility have enacted laws or implemented measures relative to divorce, legal separation or marriage as instruments of this policy. In India, the Hindu Marriage Act of 1955 required that both wife and husband should wait at least one year before remarriage after a divorce has been granted,<sup>327</sup> but this appears to represent social rather than population policy.

155. Most of the Governments of developing countries which have enunciated a policy to reduce fertility include within their broad plans for economic and social development various measures which may indirectly support their population policy aims. These include, *inter alia*, programmes to eradicate illiteracy and raise educational standards, and efforts to promote industrialization which may open employment opportunities for women in a setting more conducive to lower fertility levels. A few Governments have specifically called attention to the relation between such aspects of their development programmes and their population problems. Thus, the Governments of both India and Pakistan have cited advancements in the education of women and the provision of more employment opportunities for them as being likely to promote family planning.<sup>328</sup> It has been stated that the family planning programme in Tunisia should be viewed as an integral part of the move towards emancipation of Tunisian

women.<sup>329</sup> There appear to be few instances of Governments adopting measures to improve the status of women for the purpose of reducing fertility levels. In fact, owing to the lack of adequate studies, little is known of the ways in which improvements in the status of women may influence family size.

156. In general, there appears to have been little recourse by Governments to the application of various economic incentives and disincentives as a means of inducing couples to control fertility. There are a number of reasons for this. To begin with, most developing countries provide relatively little in the way of children's benefits. Moreover, their discontinuance where they do exist would inflict a hardship on children in large families,<sup>330</sup> and would represent retrogressive social policy. Tax reforms directed at lowering fertility have been deemed of little importance, because most families in developing regions have incomes well below the taxable level.<sup>331</sup> Finally, the effect of such measures in bringing about the desired fertility changes has been questioned. For example, Sauvy holds that family allowances in developing countries do not increase birth rates, which are "already maximal".<sup>332</sup> Similarly, Whitney has observed that whether or not a developing country has a form of family or children's allowance is apparently unrelated to the level of fertility.<sup>333</sup> On the other hand, it has been argued forcibly that incentive payments to families that limit births would have the desired effect.<sup>334</sup>

157. Some Governments have implemented, or studied the feasibility of instituting, such measures, however. The Government of India in 1965 eliminated a tax discrimination against unmarried persons.<sup>335</sup> Tunisia limits family allowances to the first four living children for wage-earners.<sup>336</sup> The Government of Ghana proposed, in a very comprehensive population policy statement, to re-examine and, if necessary, to modify policy awarding maternity benefits and tax benefits for large families and to implement other disincentives to building large families.<sup>337</sup> In recommending a population policy for Mauritius, Titmuss and his colleagues proposed a series of integrated social incentives as well as disincentives for lowering fertility. In order to encourage later marriage,

<sup>323</sup> Titmuss and Abel-Smith, *Social Policies and Population Growth* . . . (1961), pp. 242-243. These experts also proposed inducements that would in many cases advance the age to 21.

<sup>324</sup> See, for example, Majumdar and Das Gupta, "Marriage trends and . . ." (1969), p. 499 and United Nations, *Report on the Family Planning Programme in India* (1966), p. 86.

<sup>325</sup> The following are among the many articles on this subject: Agarwala, "Effects of a rise in female marriage age . . ." (1967); Basavarajappa and Belvalgidad, "Changes in age at marriage . . ." (1967); Talwar, "A note on changes in age . . ." (1967); Majumdar and Das Gupta, "Marriage trends . . ." (1969); Das, "A note on the effect . . ." (1967).

<sup>326</sup> See for example, Coale and Tye, "The significance of age-patterns . . ." (1961), p. 645 and Ryder, "The character of modern fertility" (1967), p. 30.

<sup>327</sup> Lal, *Law of Marriage and Divorce in India* (1956), p. 32.

<sup>328</sup> See the statements extracted from the government development plans in United Nations, "Government policy statements . . ." (1970), pp. 5, 7.

<sup>329</sup> Daly, "The basic aspects of population programmes in Tunisia" (1970), p. 49.

<sup>330</sup> Notestein, Kirk and Segal, "The problem of population control" (1969), p. 164.

<sup>331</sup> United Nations, *Measures, Policies and Programmes* . . . (1972), chap. I, section A-2. See also Berelson, "Beyond family planning" (1969), p. 10.

<sup>332</sup> Sauvy, *De Malthus à Mao Tsé-toung* . . . (1958), p. 217.

<sup>333</sup> Whitney, "Fertility trends and children's allowance programs" (1968), p. 133.

<sup>334</sup> See, for example, Enke, "The gains to India . . ." (1960), p. 175. Simon proposed that bonuses should be used to supplement information campaigns and urged that research be undertaken to determine their effects. See his "The role of bonuses . . ." (1968), p. 410.

<sup>335</sup> Raina, "Possible effects of public policy . . ." (1967), p. 102.

<sup>336</sup> Daly, "The basic aspects of population programmes in Tunisia" (1970), p. 48.

<sup>337</sup> Ghana, *Population Planning for National Progress and Prosperity* . . . (1969), p. 21.

they proposed the payment of a "marriage benefit" to the father of a bride, provided that both bride and groom were at least 21 years old, and that certain other conditions were met. Among their other proposals were the payment of maternity benefits under conditions that would encourage birth spacing, and a revision of the family allowance system so that there would be no increase in payments to families with more than three children.<sup>338</sup>

158. Much more attention has been given to the impact of demographic measures than to the influence of social and economic measures upon fertility, with the result that less is known of the effect of the latter. This constitutes an important gap in knowledge, and points to the considerable need for systematic research in this sphere.

## 6. PRO-NATALIST POLICIES

159. A few of the economically less advanced nations have specified a variety of conditions for which a higher rate of population growth is considered to be advantageous. These nations are mainly in Africa, and include Madagascar, Malawi and Zambia. In general, the view is that a higher rate of population growth, including a growing labour force, would be an aid to the development of resources. Sparse settlement and attendant difficulties of providing an adequate infrastructure have also been cited.<sup>339</sup>

160. The measures employed in support of pro-natalist policies differ somewhat among developed and developing nations. In the former, as noted in section C above, extensive family allowances, favourable taxation, awards for motherhood and other inducements to large families are coupled with restrictions against birth control measures, usually contraceptives and abortion. But while some pro-natalist developing nations provide allowances for children,<sup>340</sup> restrictive measures are more common, possibly because large-scale social programmes are economically unfeasible. In this connexion, it is of interest that some countries of Africa south of the Sahara have banned the import and sale of contraceptives,<sup>341</sup> and that these countries are characterized by a high to very high birth rate. However, it appears that the existing high levels of fertility in these countries are more closely

related to their very modest level of development than to the restrictive legislation concerning contraceptives, and even if contraceptives were readily available, it is unlikely that the demand for them would be very great. Whitney has pointed out that the availability of modern contraception—such as that banned by the African nations in question—is not likely in itself to result in falling birth rates.<sup>342</sup> As Freedman and others have observed, fertility will ordinarily not decline in the circumstances that prevail among the vast majority of people in these countries.<sup>343</sup>

## E. Conclusion and outlook

161. Although the subject of population policy is much broader, the present chapter focuses on the evolution of policies affecting fertility, particularly during the past twenty years. Such a time perspective is rather narrow, since it must be recognized that a profound modification of demographic trends, as further interrelated with the concurrent changes in the age structure of the population, will probably require a long time to mature.<sup>344</sup>

162. While current developments must be viewed in the framework of an extensive time perspective, the events of the 1950s and 1960s mark a radical change in public attitudes vitally affecting long-run prospects in the progress and development of the body of mankind. Prior to 1950 there had hardly ever been an explicit policy aiming at the restriction of human fertility,<sup>345</sup> though there have been, and still exist, many policies, mores and religious attitudes tending in the opposite direction. By 1970 Governments involved in the destiny of more than one-half of the world's inhabitants have pronounced themselves in favour of measures by which the increase in human numbers should be brought progressively under control. This response is remarkable when it is considered that throughout past history the size and growth of a population were nearly always considered as evidence of good government.

163. This almost sudden emergence of a new public disposition is related to the recent large acceleration of population growth in many countries. No such acceleration occurred between 1920 and 1950, but then, within a short time, an unsuspected growth potential was

<sup>338</sup> Titmuss and Abel-Smith, *Social Policies and Population Growth* ... (1961), pp. 130-135.

<sup>339</sup> United Nations, *The World Population Situation in 1970* (1971), para. 311; ———, Economic Commission for Africa, "Report of the Seminar on application ..." (1969), p. 16. It has been pointed out also that policies adopted by densely populated, low-income countries may not be appropriate for all of Latin America. See United Nations, *Social Change and Social Development* ... (1970), pp. 287-296.

<sup>340</sup> For a survey of family allowance programmes in different countries, see United States, Social Security Administration, *Social Security Programs Throughout the World* (1967) and Iyer, "Degree of protection ..." (1966), pp. 484-485.

<sup>341</sup> Two of these are the Ivory Coast and Upper Volta. United Nations, *The World Population Situation in 1970* (1971), chap. 7. The importation of contraceptives has also been made difficult in a number of other countries of Francophone Africa. Heisel, "The emergence of population policies ..." (1971), p. 33; United Nations, *Measures, Policies and Programmes* ... (1972), chap. II, section A-2(c).

<sup>342</sup> Whitney, "Fertility trends and children's ..." (1968), p. 125.

<sup>343</sup> See the discussion earlier in this section.

<sup>344</sup> See Bourgeois-Pichat and Taleb, "Un taux d'accroissement nul ..." (1970). The authors argue that on the optimistic assumption of the attainment of mortality and fertility levels consistent with an eventual stationary population by a less developed country within thirty years, the eventual stability of the population will be attained only in the course of a century, by which time the size of the population may still grow about fourfold. The crucial factor in the attainment of stability is the eventual rise in the crude death rate as a consequence of the increased proportion of the population at advanced ages, resulting from low fertility in the long run.

<sup>345</sup> Customs such as human sacrifice in ancient Carthage and pre-Hispanic Mexico, the exposure of weak children in ancient Sparta, the separation of the sexes among populations kept in a state of slavery or indentured labour and the dedication of each oldest son to celibate monkhood in pre-modern Mongolia may be cited as having had restrictive effects on population growth. A deliberate intent of population limitation, however, has not been apparent in any of those practices.

released and brought into public awareness. Mortality declines which might have been technically and organizationally feasible in the 1930s and 1940s failed to occur because of the dislocation of financial resources in the former period and the disorganization caused by war in the latter period. Then within a few years following the end of the Second World War an entire battery of new public health methods were brought into operation in wide areas of the world.

164. It is a certain fact that no biological growth, whether of an individual specimen or of an entire species, can continue forever. Even if growth is slow, it must come to a halt at some time. Whether in the near, or only in the remote future, the long-term average rate of world-population growth will eventually have to fluctuate around zero.<sup>346</sup> How long such conditions are likely to be postponed, and how much population growth can still be sustained, cannot be clearly foreseen because of unknown reserves in resources which may still be exploited and incalculable environmental controls which may be established. It seems likely that, concurrent with rapid advances in economic, social and physical development, some multiple of the present size of the world's population can still be accommodated under living conditions which will not appear intolerable. If not, then phases of population growth would inevitably have to alternate with setbacks of a magnitude greater than those ever known in history. In view of man's present and potential future social and cultural attainments, contemplation of such huge catastrophes is almost unbearable.

165. "Zero population growth" in modern times has been witnessed temporarily in France and Austria and, partly owing to net emigration, in Ireland. Because of an unusual age structure, the death rate now exceeds the birth rate in West Berlin. But in the developed countries as a whole, although decisive fertility declines have occurred, population growth still continues at an average

<sup>346</sup> Durand suggests that current population projections are consistent with declining growth rates in the developing regions after the end of the century, and that these rates may decline to about 10 per cent per decade by the year 2040, at which time the world's total population might be around 10,000 million. Even then, the twenty-first century may witness an addition to the world's population greater than that of the twentieth century. Durand, "The modern expansion ..." (1967), p. 145. Commenting along similar lines, the author of a recent study of the Organisation for Economic Co-operation and Development pointed out that for a time declining population growth rates would be offset by increasing absolute numbers, and that only by the second half of the twenty-first century could a substantial absolute decline in population growth be expected. Moreover, world population might reach 14,000-15,000 million before stabilization is achieved. Organisation for Economic Co-operation and Development, *The Food Problem...* (1968), pp. 95-96.

annual rate of nearly 1 per cent—a moderate rate when compared with the growth in less developed countries. With this comparison in view, the authors of a recent study recommend as a goal for high-fertility countries the attainment within two decades of a rate of natural increase of less than 1.5 per cent annually.<sup>347</sup>

166. As pointed out by Davis, however, the attainment of even a moderate rate of population growth is insufficient in the long run.<sup>348</sup> Since this is the level now reached in those countries where individuals are comparatively well-informed and free in their choice of alternatives, it cannot be concluded that family planning programmes, as presently understood, will suffice in solving the population problems of the world at large. The possibility cannot be discarded that more may have to be done eventually so as to commit nations and individuals to the adoption of family norms below those resulting at present from free choice.<sup>349</sup> It is possible, on the other hand, that with further population increases, social and ecological conditions will change so much as to result in individual and public preferences for even a smaller number of children than would be required to ensure stability of numbers. The experience with current family planning programmes has been too short to support any definite opinion regarding their possible long-range development. Since these programmes date back only a few years, their impact has yet to be ascertained.

167. As noted earlier, the field of population policy is broader than that of family planning, and it merges imperceptibly with various other fields of economic and social policy. It is evident, for instance, that under the combined effects of accelerated population growth and rising levels of urbanization, cities and urban regions are very rapidly growing to unprecedented sizes, producing a vast transformation in the form of the human habitat. With the growing complexity of economic systems, there will also have to be closer co-ordination of educational policy, manpower planning, housing and environmental plans, and other programmes, all of them involving population quantities. It seems likely that in the coming years population policy will extend beyond the concern with numbers to embrace also such aspects as the structure and geographic distributions of population.

<sup>347</sup> National Academy of Sciences, *Rapid Population Growth: Consequences and Policy Implications*, vol. 1 ... (1971), p. 95.

<sup>348</sup> Davis, "Population policy ..." (1967).

<sup>349</sup> According to such writers as the Ehrlichs, the explosive growth of human population has already reached a crisis state, and it is questionable whether the drastic measures needed to provide solutions will be adopted in time. Ehrlich and Ehrlich, *Population, Resources, Environment* ... (1970), particularly pp. 321-324.

### Compendia of demographic statistics

- Demographic Yearbook*. World-wide source-book of statistics of area and population, vital statistics and international migration statistics. Bilingual, English/French (1948-1971). Special topic, 1971 issue: Population census statistics I. 804 pp. Clothbound, \$28.00. Sales No. E/F.72.XIII.1. 1970 issue: Population trends.
- Population and Vital Statistics Reports* (quarterly). Gives world-wide coverage of basic demographic series for the current year. English. Annual subscription \$6.00. \$1.50 per copy. Statistical Papers. Series A.
- Monthly Bulletin of Statistics*. Provides monthly statistics from over 200 countries and territories together with special tables illustrating important economic developments. Bilingual, English/French. Annual subscription \$32.00; \$3.50 per copy.
- Problems of Migration Statistics*. English, French, Spanish. 61 pp., \$0.60. ST/SOA/Series A/5. Sales No. 50.XIII.1.

### Reports on methods and standards for demographic statistics

- Principles and Recommendations for a Vital Statistics System*. Statistical Papers, Series M, No. 19/Rev.1. English, French, Russian, Spanish. 220 pp., \$6.00. Sales No. 73.XVII.9.
- Principles and Recommendations for the 1970 Population Censuses*. Statistical Papers, Series M, No. 44. English, French, Russian, Spanish. 163 pp., \$2.50. Sales No. 67.XVII.3 (5, 6, 3).
- \* *Handbook of Population Census Methods* (3 volumes). Statistical Papers, Series F, No. 5 (Rev.1). English, French, Spanish. Vol. I—General Aspects of a Population Census, 164 pp., \$2.50. Vol. II—Economic Characteristics of the Population, 79 pp., \$1.00; Vol. III—Demographic and Social Characteristics of the Population, 78 pp., \$0.80. Sales No. 58.XVII.6.
- \* *Handbook of Household Surveys*. Statistical Papers, Series F, No. 10. English, French, Spanish. 172 pp., \$2.00. Sales No. 64.XVII.13.

### Population Bulletin of the United Nations (ST/SOA/Series N)

- \* No. 1. Articles on world population growth, international migrations in the Far East, and dynamics of age structure of populations. English, French. 57 pp., \$0.60. Sales No. 52.XIII.2.
- \* No. 2. Articles on infant mortality, assimilation of expellees in Western Germany, international migrations in the Far East, and census accuracy tests. English, French. 70 pp., \$0.80. Sales No. 52.XIII.4.
- \* No. 3. Articles on age structure of population and manpower supply in under-developed countries, census statistics of economically active population, and other subjects. English, French. 70 pp., \$0.70. Sales No. 53.XIII.8. (Article on "The measurement of infant mortality" issued in Spanish in non-sales edition, 1963.)
- \* No. 4. Articles on fertility in Australia and Ceylon and causes of aging of populations. English, French. 40 pp., \$0.40. Sales No. 55.XIII.1.
- No. 5. Selected working papers of regional seminars on population held during 1955 in Bandung, Indonesia and Rio de Janeiro, Brazil. English, French. 65 pp., \$0.60. Sales No. 56.XIII.4.
- \* No. 6. The situation and recent trends of mortality in the world; also a bibliography of selected demographic publications of the United Nations. English, French, Spanish. 210 pp., \$2.50. Sales No. 62.XIII.2.
- \* No. 7. Conditions and trends of fertility in the world. English, French, Spanish. 151 pp., \$2.00. Sales No. 64.XIII.2. (Also in Russian non-sales edition.)

### Miscellaneous demographic publications

- Multilingual Demographic Dictionary*. English, French, Russian, Spanish. 77 pp., \$1.00. ST/SOA/Series A/29. Sales No. 58.XIII.4.
- Proceedings of World Population Conferences*  
Rome, 1954 (31 Aug.-10 Sept.)
- \* *Summary report*. English, French, Spanish. 207 pp., \$1.00. E/CONF.13/412. Sales No. 55.XIII.8.
- \* *Papers*. Six volumes; papers in original languages. \$1.50 per volume. E/CONF.13/413-418. Sales No. 55.XIII.8, Vols. I-VI.
- Belgrade, 1965 (30 Aug.-10 Sept.)
- World Population: Challenge to Development*. A non-technical summary of highlights of the 1965 Conference. English, French, Russian, Spanish. 48 pp., \$0.75. E/CONF.41/1. Sales No. 66.XIII.4.
- \* *Volume I: Summary Report*. English, French, Russian, Spanish. 349 pp., \$5.50. E/CONF.41/2. Sales No. 66.XIII.5.
- \* *Papers*. Three volumes. English, French, Spanish. E/CONF.41/3-5. Sales No. 66.XIII.6-8.

### REPORTS OF UNITED NATIONS INTERREGIONAL SEMINARS ON POPULATION:

- \* *Report of the Interregional Workshop on Programmes of Training in the Field of Population* (Elsinore, Denmark, 19-30 June 1967). English, French, Russian, Spanish. 38 pp. E/CN.9/207-E/CN.9/CONF.4/1-ST/TAO/SER.C/98 (non-sales item, 1967).
- \* *Report of the Interregional Seminar on Application of Demographic Data and Studies to Development Planning* (Kiev, Ukrainian SSR, 15-25 September 1969). English, French, Russian, Spanish. 69 pp. E/CN.9/223-E/CN.9/CONF.5/1 (non-sales item, 1969).
- Report of the Interregional Seminar on Demographic Aspects of Manpower* (Moscow, USSR, 31 Aug.-11 Sept. 1970). English, French, Russian, Spanish. 34 pp. E/CN.9/240 and Corr.1 (non-sales item, 1971).
- Report of the Expert Working Group on Population Research in National Institutions* (Lyon, France, 3-11 June 1971). English, French, Russian, Spanish. 60 pp. E/CN.9/242 (non-sales item, 1971).
- Report on the Technical Meeting on Methods of Analysing Fertility Data for Developing Countries* (Budapest, Hungary, 14-25 June 1971). English, French, Russian, Spanish. 55 pp. E/CN.9/241 and Corr.1 (non-sales item, 1971).
- Report of the Interregional Seminar on Mortality Analysis* (Mamaia, Romania, 20 Sept.-3 Oct. 1972). English, French, Russian, Spanish. ST/SOA/SER.R/15-ST/TAO/SER.C/145 (non-sales item, 1973).
- Report of the Interregional Workshop on Population Action Programmes* (Manila, Philippines, 15-25 Nov. 1972). English, French, Russian, Spanish (in press). ST/SOA/SER.R/16-ST/TAO/SER.C/150 (non-sales item, 1973).

\* Out of print. Available for reference in depository and other libraries which receive United Nations material.
