

# **THE DETERMINANTS AND CONSEQUENCES OF POPULATION TRENDS**

**New Summary of Findings on Interaction  
of Demographic, Economic and Social Factors**

**VOLUME I**

**UNITED NATIONS**

# DEMOGRAPHIC PUBLICATIONS OF THE UNITED NATIONS

SELECTED LIST, JULY 1973

## Studies of population trends and problems

- The Determinants and Consequences of Population Trends: New Summary of Findings on Interaction of Demographic, Economic and Social Factors* (Volume I). English (French, Russian and Spanish in press). ST/SOA/SER.A/50. Sales No. E.71.XIII.5. *Volume II. Index and Bibliography*. ST/SOA/SER.A/50/Add.1. Sales No. 71.XIII.6.
- \* *The Aging of Populations and its Economic and Social Implications*. A world-wide survey and analysis of aging, its causes and consequences. English, French, 168 pp., \$1.75. ST/SOA/Series A/26. Sales No. 56.XIII.6.
- \* *Recent Trends in Fertility in Industrialized Countries*. A comparative analysis of the recovery of the birth-rate in various countries during and after World War II. English, French. 182 pp., \$2.00. ST/SOA/Series A/27. Sales No. 57.XIII.2.
- \* *Foetal, Infant and Early Childhood Mortality. Vol. I. The Statistics. Vol. II. Biological, Social and Economic Factors*. English, French. Vol. I: 137 pp., \$2.00. Vol. II: 44 pp., \$0.75. ST/SOA/Series A/13 and Add.1. Sales Nos. 54.IV.7 and 54.IV.8.
- \* *The Mysore Population Study*. Report of a field study of interrelationships of demographic, economic and social factors in Mysore State, India. English. 443 pp., \$4.50. ST/SOA/Series A/34. Sales No. 61.XIII.3.
- \* *Population Growth and Manpower in the Philippines*. A joint study with the Government of the Philippines. English, French, Spanish. 66 pp., \$1.00. ST/SOA/Series A/32. Sales No. 61.XIII.2.
- \* *Demographic Aspects of Manpower. Sex and Age Patterns of Participation in Economic Activities*. English, French, Spanish. 81 pp., \$1.00. ST/SOA/Series A/33. Sales No. 61.XIII.4.
- Guanabara Demographic Pilot Survey*. A joint project with the Government of Brazil, carried out in the State of Guanabara, Brazil. English, French. 77 pp., \$1.00. ST/SOA/Series A/35. Sales No. 64.XIII.3. (A Spanish version published by the Latin American Demographic Centre, Santiago, Chile.)
- Population Growth and Manpower in the Sudan*. A joint study with the Government of the Sudan on population and manpower problems. English, French, Spanish. 150 pp., \$2.00. ST/SOA/Series A/37. Sales No. 64.XIII.5.
- Growth of the World's Urban and Rural Population, 1920-2000*. English, French, Russian, Spanish. 124 pp., \$2.00. ST/SOA/Series A/44. Sales No. E.69.XIII.3.
- A Concise Summary of the World Population Situation in 1970*. English, French, Russian, Spanish. 35 pp., \$1.00. ST/SOA/Series A/48. Sales No. E.71.XIII.2.
- The World Population Situation in 1970*. English, French, Russian, Spanish. 78 pp., \$2.00. ST/SOA/Series A/49. Sales No. E.71.XIII.4.
- Measures, Policies and Programmes Affecting Fertility, with Particular Reference to National Family Planning Programmes*. English, French, Russian, Spanish. 162 pp., \$3.00. ST/SOA/Series A/51. Sales No. E.72.XIII.2.
- Interim Report on Conditions and Trends of Fertility in the World, 1960-1965*. English, French, Russian, Spanish. 89 pp., \$3.00. ST/SOA/SER.A/52. Sales No. E.72.XIII.3.

## Future population estimates

- World Population Prospects As Assessed in 1968*. Population projections to 2000 for world regions and to 1985 for each country. English, Russian (French and Spanish in press), 167 pp., \$2.00. ST/SOA/Series A/53. Sales No. 72.XIII.4.

## Reports on methods of demographic analysis and projections

- \* *Age and Sex Patterns of Mortality. Model Life Tables for Under-Developed Countries*. English, French, Spanish. 38 pp., \$0.40. ST/SOA/Series A/22. Sales No. 55.XIII.9.
- Manual I: Methods of Estimating Total Population for Current Dates*. English, French, Spanish, 45 pp., \$0.75. ST/SOA/Series A/10. Sales No. 52.XIII.5. (Also in Russian non-sales edition.)
- Manual II: Methods of Appraisal of Quality of Basic Data for Population Estimates*. English, French, Spanish. 67 pp., \$0.70. ST/SOA/Series A/23. Sales No. 56.XIII.2. (Also in Russian non-sales edition.)
- Manual III: Methods for Population Projections by Sex and Age*. English, French, Spanish. 81 pp., \$1.50. ST/SOA/Series A/25. Sales No. 56.XIII.3. (Also in Russian non-sales edition.)
- Manual IV: Methods of Estimating Basic Demographic Measures from Incomplete Data*. English, French, Russian, Spanish. 132 pp., \$2.00. ST/SOA/Series A/42. Sales No. 67.XIII.2.
- National Programmes of Analysis of Population Census Data as an Aid to Planning and Policy-Making*. A study to assist Governments in utilizing census results for purposes of planning in economic and social fields, and formulation of policy. English, French, Spanish. 64 pp., \$1.00. ST/SOA/Series A/36. Sales No. 64.XIII.4. (Also in Russian non-sales edition.)
- General Principles for National Programmes of Population Projections as Aids to Development Planning*. Guide-lines for national programmes of population projections to assist in policy-making and planning of economic and social development. English, French, Spanish. 60 pp., \$0.75. ST/SOA/Series A/38. Sales No. 65.XIII.2. (Also in Russian non-sales edition.)
- The Concept of a Stable Population: Application to the Study of Populations of Countries with Incomplete Demographic Statistics*. A technical study concerning the properties of stable, semi-stable and quasi-stable populations and their applications in analysis of demographic data of countries lacking reliable statistics. English, French, Spanish. 237 pp., \$3.50. ST/SOA/Series A/39. Sales No. 65.XIII.3.
- Estimating Future School Enrolment in Developing Countries: A Manual of Methodology*. A collaborative project with UNESCO. English, French, Spanish. 156 pp., \$2.00. ST/SOA/Series A/40. Sales No. 66.XIII.3. (Also published in UNESCO's series ST/S/10.)
- Methods of Analysing Census Data on Economic Activities of the Population*. English, French, Russian, Spanish. 152 pp., \$2.50. ST/SOA/Series A/43. Sales No. E.69.XIII.2.
- Variables and Questionnaire for Comparative Fertility Surveys*. English, French, Russian, Spanish. 104 pp., \$2.00. ST/SOA/Series A/45. Sales No. E.69.XIII.4.
- Manual V: Methods of Projecting the Economically Active Population*. English, French, Russian, Spanish. 119 pp., \$1.50. ST/SOA/Series A/46. Sales No. 70.XIII.2.
- Manual VI: Methods of Measuring Internal Migration*. English, French, Russian, Spanish. 72 pp., \$1.50. ST/SOA/Series A/47. Sales No. 70.XIII.3.
- Manual VII: Methods of Projecting Households and Families*. English (French, Russian and Spanish in press). 108 pp., ST/SOA/Series A/54. Sales No. 73.XIII.2.

\* Out of print. Available for reference in depository and other libraries which receive United Nations material.

POPULATION STUDIES, No. 50

# **THE DETERMINANTS AND CONSEQUENCES OF POPULATION TRENDS**

**New Summary of Findings on Interaction  
of Demographic, Economic and Social Factors**

**VOLUME I**

**UNITED NATIONS**  
New York, 1973

## NOTE

Symbols of United Nations documents are composed of capital letters combined with figures. Mention of such a symbol indicates a reference to a United Nations document.

Geographical areas for which statistical data are presented in this publication conform to the official country nomenclature used by the United Nations at mid-1971, when the first part of the study went to press; it has not been possible, therefore, to take into account the changes in the list of countries or in their official names, decided by the Secretary-General at a later date.

This study is published in two volumes. Volume I contains chapters I to XVII, the text of the study, and volume II the bibliography, author and subject indexes and an annex.

UNITED NATIONS PUBLICATION

*Sales No. E.71.XIII.5*

Price: \$U.S. 24.00  
(or equivalent in other currencies)

## PREFACE

The first edition of *The Determinants and Consequences of Population Trends* was published in 1953<sup>1</sup> in response to a recommendation of the Population Commission at its fourth session<sup>2</sup> that the Secretary-General should survey the existing scientific studies concerning the relationships between population trends and economic and social factors and prepare a summary of the findings of such studies with special reference to problems of economic development. In recommending that a revised edition of this study should be prepared, the Population Commission noted that the original study had proved to be a highly useful summary of facts, theories and analyses which was now in need of updating in order to take account of the results of new research and advances in knowledge of the demographic, economic and social interrelationships which had taken place since 1953.<sup>3</sup>

In the early stage of the revision of this study, numerous specialists in various fields of demography and related disciplines were invited to prepare papers in their areas

of specialty which served as background papers for the discussions at the World Population Conference, 1965. A list of these background papers and their authors is given in the annex, which appears in volume II. These papers provided a starting point for the drafting of many of the chapters of the present work. They were revised and expanded by the United Nations Secretariat with the assistance of some of the specialized agencies, the regional economic commissions, the United Nations demographic training centres, and various consultants. In order to ensure that the revised edition would reflect studies carried out in all parts of the world and take account of differing points of view, the United Nations enlisted the co-operation of five demographic research institutions in reviewing drafts of chapters, recommending additional bibliography and, in some cases, providing English or French summaries of studies published in languages with which the Secretariat was not well equipped to deal. These co-operating institutes included the following: Central Statistical Board, Council of Ministers of the Union of Soviet Socialist Republics, Moscow; Demographic Research Centre of the Institute of Social Sciences, Belgrade; Institut national d'études démographiques, Paris; Institute of Population Problems, Tokyo; and Office of Population Research, Princeton, New Jersey.

<sup>1</sup> United Nations publication, Sales No. 53.XIII.3.

<sup>2</sup> *Official Records of the Economic and Social Council, Ninth Session, Supplement No. 7.*

<sup>3</sup> *Ibid.*, *Thirty-first Session, Supplement No. 3*, para. 18; *ibid.*, *Thirty-fifth Session, Supplement No. 2*, para. 52.

## SUMMARY OF CONTENTS

<i>Chapter</i>	<b>Volume I</b>	<i>Page</i>
I. Introductory background .....		1
II. History of world population growth .....		10
III. Population theory .....		33
IV. Fertility .....		64
V. Mortality .....		107
VI. Population distribution, internal migration and urbanization .....		159
VII. International migration .....		225
VIII. Sex and age structure .....		262
IX. Demographic aspects of manpower .....		293
X. Families and households .....		335
XI. Population and natural resources .....		365
XII. Population and food .....		398
XIII. Demographic aspects of savings, investment, employment and productivity .....		434
XIV. Demographic aspects of modern economic growth .....		505
XV. Demographic projections .....		557
XVI. Demographic considerations in planning .....		589
XVII. Population policies .....		631

(A detailed table of contents of volume I is given on pp. vii-xv.)

## Volume II

Bibliography  
 Author index  
 Subject index  
 Annex

# CONTENTS

## Volume I

<i>Chapter</i>	<i>Page</i>
<b>I. INTRODUCTORY BACKGROUND</b>	
A. The widening compass of population research .....	1
1. Improvements in statistical data .....	1
2. Expansion of demographic research .....	2
3. Improvements in methodology and techniques .....	2
4. New demographic trends .....	3
5. Improved knowledge of interrelationships between population and economic and social factors .....	5
6. New concern with population policy .....	6
7. The development of demography as a scientific discipline and its relation to other disciplines .....	6
8. Gaps in knowledge .....	7
B. Organization of the study .....	9
<b>II. HISTORY OF WORLD POPULATION GROWTH</b>	
A. Palaeolithic to early historic period .....	10
B. Population of the ancient world .....	15
C. Population trends: ancient to modern times .....	16
D. Population growth in the modern period .....	20
1. Europe .....	23
2. Union of Soviet Socialist Republics .....	26
3. North America .....	27
4. Latin America .....	27
5. Oceania .....	28
6. Asia .....	28
7. Africa .....	30
E. Summary of regional trends, 1750-1965 .....	31
<b>III. POPULATION THEORY</b>	
A. Ancient and mediaeval writings on population .....	33
B. Towards modern theory .....	35
1. Mercantilist, physiocratic and related views .....	35
2. Political arithmetic .....	37
C. Malthus and his theory .....	38
D. The classical and neo-classical schools of economics and population theory	40
1. Malthus' population theory and the theory of economic growth of the classical school .....	40
2. Criticisms of Malthus' theory by non-socialist writers .....	42
3. The neo-classical school and population theory .....	43
E. Socialist and Marxist writings .....	45
1. Early socialists .....	46
2. Marx and Engels .....	46
3. Post-Marxian socialists .....	48

III. POPULATION THEORY (*continued*)

F. Contributions of other disciplines .....	51
1. Mathematical theories: the "logistic" law and related theories of population growth .....	52
2. Biological theories .....	53
3. Sociological theories .....	54
G. Focus on population .....	55
1. Optimum population theory .....	55
2. Theoretical demography .....	57
H. Recent developments .....	58
1. The theory of demographic transition .....	58
2. Population and economic development .....	60

## IV. FERTILITY

A. Levels and trends of fertility .....	64
1. Areas of low fertility .....	65
2. Areas of high fertility .....	70
B. Physiological variables affecting fertility .....	72
1. Maximum fertility rates .....	73
2. Age limits of the reproductive period .....	74
3. Post-partum sterility .....	74
4. Involuntary foetal mortality and other forms of sterility and subfecundity .....	75
C. Customs and practices affecting fertility .....	77
1. The intermediate variable framework .....	77
2. Age of entry into sexual unions (age at marriage); permanent celibacy .....	79
3. Amount of reproductive period spent after or between unions .....	82
4. Voluntary abstinence (social taboos on sexual intercourse) .....	82
5. Foetal mortality from voluntary causes (abortion) .....	83
6. Voluntary infecundity (sterilization) .....	84
7. Use or non-use of contraception .....	84
D. Factors related to past declines of fertility in areas where fertility is low .....	86
1. Cultural factors .....	87
2. Economic and social factors .....	88
E. Factors related to levels and trends of fertility in high-fertility areas ....	92
1. Cultural factors and factors related to family structure and function .....	92
2. Economic, social and other factors .....	95
F. Recent and current fertility differentials within countries .....	96
1. Urban-rural differences .....	97
2. Educational status .....	98
3. Economic status groups .....	99
4. Occupational groups .....	100
5. Employment of women .....	101
6. Religious and ethnic differences .....	102
G. Prospects for future trends of fertility .....	105
1. Prospects in areas where fertility is now high .....	105
2. Prospects in areas where fertility is now low .....	106

## ✓ V. MORTALITY

A. Levels and trends of mortality .....	108
1. Recent mortality levels .....	108
2. Past trends .....	110
B. Sex and age patterns of mortality .....	115
1. Sex differences in mortality .....	115
2. Age differences in mortality .....	118
C. Foetal and infant mortality .....	121
1. Stillbirths and perinatal mortality .....	122
2. Levels and trends of infant mortality .....	123
3. Characteristics of infant mortality .....	126
4. Factors affecting foetal and infant mortality .....	126
D. Causes of death .....	128
E. Mortality differentials .....	132
1. Urban-rural differentials .....	132
2. Geographical differentials .....	136
3. Occupational and other differentials .....	137
4. Differentials among ethnic groups .....	140
F. Factors related to high mortality in the past .....	142
1. Famines and food shortage .....	142
2. Epidemic diseases .....	143
3. War losses .....	144
4. Poor conditions in urban areas .....	145
G. Factors in mortality decline in developed countries .....	146
1. Economic development and rising income levels .....	146
2. Sanitary reforms and public health measures .....	147
3. Social reform .....	148
4. Advances in medicine .....	149
5. "Natural" factors .....	151
H. Factors in mortality levels and trends in developing countries .....	152
1. Factors in recent mortality decline .....	152
2. Factors in the persistence of high mortality in certain regions .....	155
I. Prospects for future trends .....	157
1. Prospects in areas of relatively high mortality .....	157
2. Prospects in areas of relatively low mortality .....	157

## VI. POPULATION DISTRIBUTION, INTERNAL MIGRATION AND URBANIZATION

A. Distribution of world population .....	160
1. Geographical factors .....	162
2. Social and economic factors .....	168
3. Demographic factors .....	170
4. Changes in factors affecting the distribution of population in modern times .....	172
B. Internal migration .....	173
1. Definitions .....	173
2. Principal sources of data .....	173
3. Methods of migration measurement .....	174
4. Principal internal migrations of modern times .....	175

VI. POPULATION DISTRIBUTION, INTERNAL MIGRATION AND URBANIZATION (*continued*)

C. The distribution and growth of urban and rural population .....	183
1. The distribution of urban and rural population in 1965 .....	184
2. The growth of urban and rural population in modern times .....	187
3. Demographic components of urban and rural growth .....	196
D. Factors affecting urban-rural population distribution .....	200
1. Observed conditions attending modern urbanization .....	200
2. General theories concerning internal migration .....	209
3. The economic functions of cities .....	212
4. The location of economic activities .....	213
5. Central place theory .....	214
6. "Laws" of city-size distribution .....	215
E. Policies and programmes affecting urban and rural population distribution	217
1. Return of rural migrants .....	218
2. Rural development .....	219
3. Decentralization of industry .....	220
4. Construction of new towns .....	221
5. Development of growth poles .....	221
6. Redevelopment of the big city .....	222

## VII. INTERNATIONAL MIGRATION

A. Migration trends in recent times .....	225
1. International migrations of Europeans .....	225
2. International migrations of Asians .....	233
3. International migration in Africa .....	234
B. Factors affecting international migration .....	237
1. Economic, social and other factors .....	237
2. Government policies .....	240
C. The effect of immigration and emigration on the growth and structure of populations .....	245
1. The effect on population growth .....	245
2. The effect on sex and age structure .....	248
D. Economic effects of migration .....	250
1. Effects on the labour force .....	250
2. Effects on employment and unemployment .....	253
3. Effects on wage levels .....	254
4. Effects on the balance of payments .....	255
5. Other economic consequences .....	255
6. Economic effects of selected post-war migration .....	256
E. Social aspects of migration .....	258
1. Social goals of immigration .....	258
2. Social absorptive capacity .....	259
3. Factors affecting integration .....	259
4. Social problems arising from migration .....	260

## ✓ VIII. SEX AND AGE STRUCTURE

A. Patterns of sex and age structure .....	262
1. Sex structure .....	262
2. Age structure .....	264

Chapter	Page
VIII. SEX AND AGE STRUCTURE ( <i>continued</i> )	
B. Determinants of sex and age structure .....	270
1. Factors determining sex structure .....	270
2. Factors determining age structure .....	273
C. Demographic effects of sex-age structure .....	281
D. Economic and social implications of sex and age structure .....	285
1. Dynamics of main functional groups .....	286
2. General implications .....	288
3. Implications of an aging population .....	289
IX. DEMOGRAPHIC ASPECTS OF MANPOWER	
A. Levels and trends of the labour force .....	294
1. The total labour force .....	295
2. Dependency burden .....	298
3. The male labour force .....	298
4. The female labour force .....	303
B. Demographic and economic factors in labour force size and growth .....	310
1. The roles of fertility, mortality, population age structure and age-specific activity rates .....	310
2. The role of migration .....	313
3. Effects of income, education and employment conditions .....	315
C. Length of working life and its implications .....	318
1. Tables of working life .....	318
2. Dynamic functions of the labour force .....	319
3. Expectations of earnings and consumption .....	321
D. Economic structure of the labour force .....	321
1. Regional variations .....	322
2. Changes in the process of economic growth .....	323
E. Unemployment and underemployment .....	329
1. Measures and levels of unemployment .....	329
2. Measures and levels of underemployment .....	332
3. Estimates of "labour surpluses" in agriculture .....	333
X. FAMILIES AND HOUSEHOLDS	
A. General definitions and concepts .....	336
B. Regional variations in the size and structure of families and households ..	337
C. Trends in the size and structure of families and households .....	340
1. Multiphasic changes in structure .....	340
2. Secular changes in average size and structure .....	342
3. Demographic transition and decline in average household size .....	347
D. Patterns and differentials in headship rates .....	347
1. Notion of the headship rate .....	347
2. Sex-age-specific headship rates in countries at different levels of development .....	348
3. Sex-age-specific headship rates by three major <i>per capita</i> income groups .....	349
4. Change in sex-age-specific headship rates .....	350
5. Patterns of sex-age-marital status-specific headship rates .....	351

Chapter	Page
X. FAMILIES AND HOUSEHOLDS ( <i>continued</i> )	
E. Factors affecting the number and size of families and households .....	352
1. Major regional differences .....	352
2. Sex-age structure .....	353
3. Fertility and mortality .....	354
4. Marriage and marital status .....	356
5. Economic and social factors .....	357
F. The life cycle of the family .....	361
1. Family life cycle as a demographic framework .....	361
2. Stages in the family life cycle .....	362
3. Length of stages in the family life cycle .....	363
G. Summary .....	364
XI. POPULATION AND NATURAL RESOURCES	
A. Concept of natural resources and problems of measurement .....	368
B. Recent views on natural resources .....	370
C. Classification of natural resources .....	373
1. Atmosphere .....	373
2. Hydrosphere .....	376
3. Lithosphere .....	379
4. New sources of energy .....	387
D. Factors affecting supply of natural resources .....	389
1. Reserves .....	390
2. Stage of technology .....	390
3. International trade .....	392
E. Factors influencing demand for natural resources .....	393
1. Growth of population .....	393
2. Average income .....	394
3. Stage of technology .....	395
4. Price-cost structure .....	395
5. Institutional patterns .....	396
F. Relation of natural resources and population to development .....	396
XII. POPULATION AND FOOD	
A. The population and food dilemma .....	398
B. Population and food requirements, nutrition and the demand for food ..	403
1. Recent trends in world population and food production .....	403
2. Recent trends in international trade and food supply .....	406
3. Food supplies and levels of nutrition .....	408
4. The demand for food .....	411
C. Population and agriculture .....	413
1. Agricultural land and its productivity .....	414
2. Agricultural labour and its productivity .....	421
3. Possibilities of increasing food supplies .....	425
D. Outlook and projections .....	427
1. Projections of requirements .....	428
2. Projections of demand .....	429
3. Projections of production and the reconciliation of demand and supply	432

### XIII. DEMOGRAPHIC ASPECTS OF SAVINGS, INVESTMENT, EMPLOYMENT AND PRODUCTIVITY

A. Demographic aspects of savings .....	434
1. Population size, density and savings .....	436
2. Age distribution and savings .....	436
3. Population growth and savings .....	446
4. International migration and savings .....	449
5. Internal migration and savings .....	450
6. Demographic and non-demographic determinants of savings .....	451
B. Demographic aspects of investment .....	452
1. Population size, density and investment .....	454
2. Age distribution and investment .....	454
3. Population growth and investment .....	455
4. International migration and investment .....	463
5. Internal migration and investment .....	464
6. Demographic and non-demographic determinants of investments ....	465
C. Demographic aspects of employment .....	465
1. Population size and employment .....	467
2. Age distribution and employment .....	470
3. Population growth and employment .....	472
4. International migration and employment .....	478
5. Internal migration and employment .....	479
6. Demographic and non-demographic determinants of employment ....	480
D. Demographic aspects of productivity .....	481
1. Population size and productivity .....	482
2. The age distribution and productivity .....	489
3. Population growth and productivity .....	491
4. International migration and productivity .....	500
5. Internal migration, urbanization and productivity .....	502
6. Demographic and non-demographic determinants of productivity ....	503
E. Some principal interrelations .....	503

### XIV. DEMOGRAPHIC ASPECTS OF MODERN ECONOMIC GROWTH

A. Economic growth: definition and manifestations .....	506
B. Population and economy in the modern period .....	508
1. Economic growth and demographic change in the period of modern economic growth .....	509
2. Industrialization and urbanization in the period of modern economic growth .....	520
C. Recent evolution and situation .....	522
1. Economic growth and demographic change in the post-war period ..	523
2. Some implications and associations of recent economic and demographic trends .....	529
D. Population and economic growth in the past and present .....	548
1. Early modern economic growth and population in the presently developed countries .....	548
2. The relevance of past economic and population trends for the presently less developed countries .....	551
E. Over-all view and some tentative conclusions .....	554

<i>Chapter</i>	<i>Page</i>
XV. DEMOGRAPHIC PROJECTIONS	
A. Demographic projections in historical perspective .....	558
B. Regional and world projections .....	561
1. Development of country projections .....	561
2. Development of regional and world projections .....	562
3. World population prospects as recently assessed .....	563
C. Types of specialized demographic projections .....	570
1. Labour force .....	571
2. Urban and rural population .....	575
3. Agricultural population .....	579
4. Education .....	581
5. Households and families .....	583
6. The need for a co-ordinated system of demographic projections .....	585
D. The use of demographic projections in planning .....	586
1. Industrial development .....	586
2. Agricultural development .....	587
3. Education .....	587
4. Health .....	587
5. Housing .....	588
6. Regional and urban development .....	588
XVI. DEMOGRAPHIC CONSIDERATIONS IN PLANNING	
A. Approaches to planning and the role of population .....	589
B. Demographic considerations in economic planning .....	592
1. The centrally planned economies .....	595
2. The developed private-enterprise and mixed economies .....	599
3. The developing countries .....	603
C. Planning for education, health and housing .....	612

### EXPLANATORY NOTES

The following symbols are used in the tables in this publication:

Three dots (...) indicate that data are not available or are not separately reported.

A dash (—) indicates that the amount is nil or negligible.

A blank in a table indicates that the item is not applicable.

*Developing regions* include Africa, Asia except Japan, Latin America except Temperate South America, and Oceania except Australia and New Zealand.

*More developed regions* include Japan, Europe, Temperate South America, Northern America, Australia and New Zealand, and the Union of Soviet Socialist Republics.

### FOOT-NOTE REFERENCES

Foot-note references include author's last name, title or partial title and year of publication only. Complete references are given in the Bibliography in volume II, which is alphabetically arranged by author.

## Chapter I

### INTRODUCTORY BACKGROUND

1. The present study, like the first edition of *The Determinants and Consequences of Population Trends*,<sup>1</sup> is conceived as an analytic inventory of existing knowledge and hypotheses concerning the factors affecting population trends and the influence of these trends upon economic and social conditions. By reviewing relevant literature in demography, economics, sociology, geography, history and other related fields, the new edition aims at synthesizing the findings of major research on population change throughout the world and on its economic and social correlates.

2. The period between the publication of the first and present editions of this study was marked by a vast upsurge in demographic literature, reflecting a number of developments. Most important, spectacular changes in demographic trends were taking place—the foremost being the sharp acceleration of world population growth. At the same time a wealth of new demographic data were becoming available, even for areas for which such data had previously been lacking, and the development and improvement of techniques for estimating demographic measures from defective data contributed to a better knowledge of demographic conditions and trends in these areas. The new demographic trends stimulated greater interest in population matters and provided a challenge both to scholars and those concerned with policy matters; as a result, great efforts were expended to analyse the causes and consequences of the new developments and their policy implications, including programmes and actions required, or considered desirable, for modifying these trends.

3. The revision of *The Determinants and Consequences of Population Trends* was undertaken at a time when the United Nations was becoming increasingly involved in the population field and when important debates and decisions on population and corresponding economic and social policies were being held in the parliamentary bodies of the United Nations. Critical changes were taking place in attitudes towards population matters and new kinds of policies were being developed by a number of Governments. This was also a time when there was a growing recognition of the important role of population in economic and social development. The bringing together of the findings of major research in this area, it was hoped, would be of assistance to Governments and international bodies in formulating appropriate policies and programmes to speed the development process. It was considered that such a summary would be useful both for the development of policies designed

to influence population trends, as well as for the formulation of economic and social programmes designed to take account of the consequences of a growing population. With respect to the latter aspect, it is clear that the size of the population, its rate of growth, and its composition and geographical distribution are important factors in determining present and future needs of a country in such areas as education, housing, health services, food supply, and the like, as well as its productive capacity. Effective planning to provide full employment and a growth in labour productivity requires a knowledge of the present size and composition of the labour force and its prospective changes. In order to make forecasts in all of these areas, knowledge is required of the factors influencing population trends, and application of the projections in appropriate development measures requires an understanding of the probable economic and social effects of population change. In addition, concern that rapid population growth might hamper development efforts has led numerous Governments to adopt policies aimed at influencing their birth rates. For such policies to be effectively implemented, knowledge of the factors affecting human reproductive behaviour is essential.

4. Some of the major developments in the field of population which have occurred since the publication of the first edition of the present study are further elaborated below.

#### A. The widening compass of population research

##### 1. IMPROVEMENTS IN STATISTICAL DATA

5. Major changes in the political map of the world occurred after 1945 with the emergence of new national sovereignties in many parts of the world. This circumstance in itself called for improvements in basic information and statistics concerning all aspects of life in the newly independent nations. As part of the efforts to improve national statistical systems, the United Nations enlisted the co-operation of Governments in carrying out the first world census programme around 1950; this was followed by similar programmes in 1960 and 1970.

6. The progress made in the statistical documentation of the world's population can be assessed from two analyses undertaken in 1960 and 1970, respectively.<sup>2</sup> Of the four population giants—China, India, the Union of Soviet Socialist Republics and the United States of

<sup>1</sup> United Nations publication, Sales No. 53.XIII.3.

<sup>2</sup> United Nations, *Demographic Yearbook, 1960 ...* (1961), pp. 1-12; ———, *Demographic Yearbook, 1970 ...* (1971), pp. 1-10.

America, which together contain nearly one half of the world's population—all except China had censuses around 1960 and 1970. Excluding these four countries, it was found that for the countries which make up the remainder of the world, data based on censuses accounted for 78 per cent of their combined population in 1959, and for 90 per cent in 1969. Notable progress in census-based estimates occurred in Africa and Asia during this interval. After weighing the possible sources of error in current population estimates, it was suggested that the absolute range of error in the estimated world population totals might have been about 111 million in 1959 and 113 million in 1969. In relative terms, however, this error range decreased from 3.8 per cent in 1959 to 3.1 per cent in 1969. The largest source of error continued to be an uncertainty of information concerning the population of China.

7. Efforts to develop or improve vital statistics systems have been successful in some developing countries, but in general such systems are still far from being adequate to provide reliable estimates of birth and death rates in the world's less industrialized areas. Around 1965, complete birth registration statistics were available for countries containing about 35 per cent of the world's population; for the less developed regions, the comparable figure was estimated to be only 5 per cent.<sup>3</sup> Of the world's four most populous countries, only the Union of Soviet Socialist Republics and the United States of America maintain reliable statistics of births and deaths. For an increasing number of developing countries lacking reliable vital statistics, estimates based on sample surveys or derived from census data have become available in recent years. The extent of improvement in the availability of data is suggested by the fact that, whereas a 1957 study of the United Nations<sup>4</sup> gave registered or estimated birth rates for only five countries in Africa and fourteen in Asia, the United Nations study published in 1972 included such data for thirty-three countries in Africa and twenty-nine in Asia.<sup>5</sup>

8. Population registers established in a number of countries have proved to be a useful source of data, in particular for measuring migration volumes. National sample surveys have come into frequent use, either to supplement data obtained from population censuses, or to provide a substitute for census or vital registration data when the latter are lacking or deficient. Many of these surveys have focused on investigations of the labour force and have contributed to an improved knowledge of employment and unemployment conditions, particularly in pre-industrial societies.

## 2. EXPANSION OF DEMOGRAPHIC RESEARCH

9. Along with the improvement of statistical information on the population, two major features of demographic

<sup>4</sup> United Nations, *Report on the World Social Situation ...* (1957), pp. 6-9.

<sup>5</sup> United Nations, *Interim Report on Conditions and Trends of Fertility ...* (1972), table 1, p. 58.

research during the past two decades call for comment. The first is the rapid growth and diversification of research, leading to a high degree of specialization among the individual branches of demography, such as fertility research, urban studies etc.<sup>6</sup> The second feature is a gradual change in the orientation of demographic research. Already in the early 1950s there was a growing interest among demographers in economic and social aspects of demographic change. At the close of the 1954 World Population Conference, the president of the International Union for the Scientific Study of Population, Mr. L. Hersch, stated: "Even now, however, the Conference may lay claim to certain rather substantial accomplishments. It has in various ways brought to light the multitude and variety of the links between demography and social phenomena in general and has thus at long last broken through the narrow circle of pure demography and the scientific isolationism so dear to the demographers of the nineteenth and the early twentieth centuries."<sup>7</sup> Another important change occurred in the early 1960s when demographic research became increasingly influenced by the gradual emergence of government policies. This new trend manifested itself first in a response to a growing demand for demographic analysis and projections needed in economic and social planning. Gradually, research underpinning the formulation of population policies attracted the attention of scientists and technicians, for it became evident that comprehensive international and national development programmes require that policies designed to influence population trends be included as a major component. The United Nations has played a role in this new development through its efforts to assist Governments with studies that would contribute either to the formulation of policies or to the implementation of adopted policies.

## 3. IMPROVEMENTS IN METHODOLOGY AND TECHNIQUES

10. Some of the major advances in demography since the 1950s have taken place in the area of methodology and techniques. More refined analytical tools have recently appeared in every field of demography. The revitalization and further development of stable population theory and the variety of methodological techniques derived therefrom proved to be a turning point in demographic analysis, as methodological progress was followed by practical applications. Thus, the demographic models developed in the early 1950s made possible a systematic analysis of the effects of different fertility and mortality levels on the age structure of the population and led, *inter alia*, to a better understanding of the causes of ageing of the population than had been possible previously. The extension of stable population analysis to the economically active population has provided a con-

<sup>6</sup> In 1953, when the first edition of *The Determinants and Consequences of Population Trends* was published, the authoritative bibliography, *Population Index*, published by Princeton University's Office of Population Research, contained a total of 2,236 listings for the year. By 1971 the number of entries in *Population Index* had grown to more than 3,700. In 1953 the various books and articles listed in this bibliography were grouped under only eleven main subject headings, whereas in 1971 nineteen main headings and about seventy subheadings were identified.

<sup>7</sup> United Nations, "Closing of the Conference" (1955), p. 181.

venient means for assessing the effects of different fertility and mortality levels operating through the age structure, as well as of different patterns of age-specific activity rates on total activity rates, dependency ratios, labour force replacement rates etc.

11. Stable and quasi-stable population analysis as well as other techniques are now widely applied in estimating basic demographic variables for countries with inadequate data. Among the techniques used, particularly with respect to data for African countries, are those involving the analysis of retrospective data on numbers of children ever born and numbers surviving; another is the method of "reverse-survival" of census-age data to derive birth-rate estimates.

12. Improved methodology for reconstructing demographic measures for early periods has contributed to progress in historical demography. For example, it has been possible to estimate long-term mortality trends extending from the middle of the nineteenth century for European countries and for some countries of overseas European settlement.

13. Multiple decrement life tables, which combine mortality rates with other demographic or socio-economic characteristics, have come into wider use. In particular, various types of nuptiality tables and working life tables have proved to be useful tools for analysis in their respective areas, and school-life tables and migration expectancy tables have shown much promise.

14. The techniques of population projection have been further advanced in the last two decades. Not only has the method of component projection replaced less adequate methods, but there has been an extension of the scope of projections to cover the different sectors or socio-economic categories of the population. Thus, there has been a trend towards providing a co-ordinated system of projections in such areas as labour force, rural and urban population, agricultural and non-agricultural population, school enrolment and households and families.

15. The development of mathematical demography has made notable progress. Advanced statistical and mathematical techniques have found their uses in model building and in research on the interaction between demographic, economic and social change. The utilization of matrix algebra and Markov chains to represent complex demographic phenomena has been facilitated by the advent of electronic computers. Large-storage computers have made possible the construction of highly complicated micro-simulation models which can include a large number of demographic and socio-economic variables and can ascertain their intricate mutual interrelationships.

16. In the area of fertility studies, greater use has been made of the cohort method of analysis; new methods have been developed for analysing distributions of births by birth order and parity progression ratios have been constructed for calculating birth probabilities. Progress has been made in determining fecundability periods of women with greater precision so as to improve the accuracy of calculations of pregnancy and birth probabilities. The possibilities have been explored of predicting actual future family size from desired family sizes reported

by couples. Intensive studies in the area of family planning have brought into widespread use KAP surveys for investigating the extent of knowledge, attitudes and practices concerning birth control. The multiple decrement life table approach has been applied in attempting to measure the use-effectiveness of various contraceptives for estimating births averted by various family planning methods. Path analysis, used earlier in social mobility studies, has been applied in studying the effects of family planning programmes on fertility.

17. The development of theoretical frameworks for the study of demographic phenomena has contributed to more systematic analyses in certain areas. For example, the analysis of factors affecting fertility has been facilitated by the use of a framework of intermediate variables through which social variables operate. Efforts have also been made to develop a commonly accepted framework for studying the effects of economic and social factors and their interaction on individual family choices concerning family size. Frameworks for migration analysis have also been proposed, but partly because of the many diverse types of migration and the complexity of migratory movements—which involve determinants at both the points of origin and destination—no particular framework has come into general use. In another area of demography, the further refinement of the concept of the "life cycle of the family" has provided a basis for more comparable research on changes in the size and structure of families and for studies of household income and expenditure; of particular interest is its application in studies of the dynamics of family building.

#### 4. NEW DEMOGRAPHIC TRENDS

18. The period between 1950 and 1970 saw the world's population growing at an average rate of 1.9 per cent annually—more than twice the rate of growth experienced during the first half of the twentieth century. This greatly accelerated growth of world population is the outstanding demographic fact of the past two decades. As table I.1 shows, an upturn in the rate of population growth occurred in the more developed as well as the less developed regions during the recent period, though it was far more spectacular in the latter. This trend, which was already becoming apparent at the time the first edition of the present study was published, was verified by the results of the 1960 round of censuses. As a result of the revelations of the 1960 censuses, a number of Governments found that their populations were growing faster than they had expected and they realized that this rapid growth might adversely affect economic and social progress and the improvement of levels of living.

19. Successful campaigns against disease had reduced mortality even in those areas of the world where, until recently, population growth had been held in check by high death rates. By the 1960s, according to United Nations estimates, crude death rates had fallen to about 9 per 1,000 population in the more developed regions and to about 17 in the developing regions—about half as high as the levels estimated for the first half of the twentieth century in both sets of regions (table I.2). While

TABLE I.1. TOTAL POPULATION ESTIMATES AND ANNUAL RATES OF INCREASE FOR THE WORLD, DEVELOPING AND MORE DEVELOPED REGIONS, 1900-1950

Major area	Total population (millions)			Average annual rate of increase (percentage)	
	1900	1950	1970	1900-1950	1950-1970
World total .....	1,650	2,486	3,631	0.8	1.9

TABLE I.2. ESTIMATED AND CONJECTURED AVERAGE ANNUAL BIRTH RATES, DEATH RATES AND RATES OF NATURAL INCREASE FOR THE DEVELOPING AND MORE DEVELOPED REGIONS OF THE WORLD, 1900-1970  
(Rates per 1,000 population)

Period	Developing regions			More developed regions		
	Birth rate	Death rate	Rate of natural increase	Birth rate	Death rate	Rate of natural increase
1900-1950 .....	41	32	9	26	18	8
1950-1960 .....	43	22	21	22	10	12
1960-1970 .....	41	17	24	20	9	11

SOURCE: United Nations, *The World Population Situation in 1970* (1971), table 3, p. 7.

birth rates showed a long-term descent—although with some fluctuations—in the more developed regions, those in the developing regions continued at a high level, with the result that the recent acceleration of population growth experienced in these countries is without precedent in the world's history.

20. While previously it had been possible to deduce only that fertility was high in the non-industrialized regions of the world, the improved estimates which have recently become available suggest surprisingly wide variations in fertility levels among the different geographical regions and subregions. Thus, fertility levels in these countries are now known to be more diverse than was formerly presumed. There is little indication as yet that fertility is falling in the most populous countries of the developing regions, although China—which lacks adequate data—may be an exception. Clear downward trends have appeared rather recently in certain other countries in the Chinese culture zone in Asia, as well as among small island populations in the Caribbean area and elsewhere. In the industrialized countries, the 1950s had seen some upturn of the birth rate, particularly in the areas of overseas European settlement. In the 1960s, however, birth rates receded in most of these areas, and the range of variation of birth rates in the industrialized countries became rather narrow.

21. Among the significant features of recent mortality trends has been a rise in death rates among middle-aged or older men in some highly industrialized countries. In these countries, where mortality had already reached low levels and infectious diseases had been brought completely under control, cardio-vascular diseases have become the most important cause of death. In some of the same countries, where infant mortality had also reached low levels, there has been a slackening in the rate of its further

decline. Meanwhile, striking declines in infant deaths have been recorded in certain developing countries, so that by the late 1960s, there was some overlapping of rates between developed and developing countries. This trend has brought into question the dependability of the infant mortality rate as an indicator of social and economic development. Most assessments of recent mortality decline in developing countries have attributed the causes mainly to advances in the control of disease and the development of health services rather than to improvements in economic conditions. Thus, it is generally concluded that the linkage between the level of economic development and the level of mortality has been weakened. This is not to deny, however, that important differences still exist in mortality conditions in different parts of the world. In fact, such differences exist even among the less developed regions and it is particularly in Africa that average life expectancy still lags disturbingly far behind the levels achieved elsewhere.

22. Next to the general acceleration of world population growth, probably the most significant demographic trend in recent years has been that of rapid urbanization. During the 1950s the urban population of the world was estimated to be growing at an average rate of 3.4 per cent per year and in developing regions it grew by about 4.7 per cent annually. While a large proportion of this growth could be attributed to the high rate of natural increase, migration from rural areas was also an important factor. In fact, in developing countries, as in most parts of the world, migration from rural to urban areas has become the predominant form of migratory movement. In developing countries much of this movement takes place because of unfavourable rural conditions and continues despite frequently high levels of unemployment in the cities.

23. Considerable changes have occurred in the volume and nature of international migration currents during the 1950s and 1960s. While the traditional streams of Europeans to overseas settlement areas have continued, the volume was considerably reduced from that of earlier peak periods. Meanwhile, however, important new currents have appeared, such as the movements from Southern Europe, North Africa and Turkey to Northern and Western Europe; from the British Commonwealth to the United Kingdom; and from Latin America to Northern America. Most of these movements have resulted from a geographic re-distribution of comparative economic opportunities. In a significant policy change, the major immigration countries of Northern America and Oceania have replaced ethnic criteria for immigrants with specifications as to desired skills—a shift which has had noticeable effects on international migrant flows. The phenomenon of the “brain drain”, whereby rich countries have been able to attract intellectual manpower from the less developed countries, has come into prominence as a problem to which solutions are still being sought.

#### 5. IMPROVED KNOWLEDGE OF INTERRELATIONSHIPS BETWEEN POPULATION AND ECONOMIC AND SOCIAL FACTORS

24. Recent literature has provided a better factual basis for understanding some of the important relationships between demographic, economic and social factors. Various studies have established that correlations exist between certain factors, though they often permit no conclusions concerning cause-effect relationships. The findings of some of these studies have suggested hypotheses—still to be tested—concerning the factors affecting demographic variables and the influence of population trends on economic and social conditions.

25. One such example is provided by studies which have examined the correlations between fertility levels in developing countries and indicators of their social and economic development. The findings of these studies have led to the development of the “threshold” hypothesis, which holds that improving economic and social conditions are not likely to have much impact in bringing down fertility in developing countries until a certain threshold level of development is achieved; but once such a level of development is attained, fertility is likely to decline spontaneously and decisively. Deviations from this pattern have been observed in certain circumstances, however, such as the cases where fertility has tended to be positively correlated with rises in the level of living. Recognizing the complex character of these relationships, various scholars have attempted to further elaborate upon or modify the threshold hypothesis.

26. Some of the new facts brought out by studies of fertility levels and trends in developing countries have led to a reappraisal of the theory of demographic transition, particularly with respect to its applicability in predicting the course of fertility change in developing countries. While this theory was based on events which occurred in the now industrialized countries, it is recognized that there was considerable variability in the demographic response to economic and social change in these coun-

tries and that it has not been possible to determine the precise relationship of particular economic and social changes to fertility decline. Observations of certain conditions and trends among the presently developing countries—such as periodic fluctuations in the birth rate, the existence of fertility differentials apparently unrelated to economic and social conditions and the failure of fertility to decline in some countries which have experienced considerable economic progress—suggests the complexity of the processes of change and the inadequacy of any simple model to explain them.

27. Various socio-economic theories have been advanced in recent years in attempts to provide explanations of family-size choices at the individual household level. Some of these have relied mainly on economic considerations, such as income, the marginal utility of children and costs of children including costs of opportunities foregone by parents, while others have given greater emphasis to factors of a more sociological nature, such as income relative to social status and individual preferences and tastes. Further interdisciplinary research in this area may reasonably be expected to lead to refinements of these theories and to a more generally accepted framework for socio-economic analysis of fertility.

28. While, as mentioned above, mortality levels in many developing countries have been sharply reduced by the application of health measures and modern medical techniques, a number of studies have suggested that further declines may depend more on economic and social development and that the less industrialized countries are not likely to achieve the very low levels of mortality prevailing in the most advanced countries without progress in raising general levels of living. In the more developed countries, studies continue to provide evidence of the influence of social class on mortality, but such differences appear to have narrowed drastically where general mortality has reached a low level.

29. A wealth of new literature has analysed different aspects of internal migration and population redistribution within metropolitan regions of different countries. Some of these studies have provided insight into the interrelationships between these demographic processes and industrialization and economic development. Empirical data confirm a general positive relationship between industrialization and urbanization, but the association is not a simple one. The findings suggest that the relation between urbanization and industrialization may be different at different levels of development and that countries with similar urbanization levels may differ with respect to their stage of industrialization. In particular, various studies have shown that recently in the less developed countries urbanization has outpaced industrialization, with the result that many of these countries are considered to be “over-urbanized” in relation to the industrial employment opportunities they are able to provide.

30. Improved knowledge of the relationship between population growth and economic growth has become especially urgent since the Governments of developing countries, which have accorded a high priority to economic advancement, are currently faced with more massive population growth than has been experienced at any

previous stage of history in any part of the world. Recent demographic literature clearly reflects this concern; in fact, there has been a decided decline in the number of studies considering the possible economic effects of a declining population—a preoccupation of industrialized countries in the 1930s—and an upsurge in those examining the probable effects of rapid population growth on the development efforts of agricultural countries. Analytical studies, models and projections have shown that the rapid population growth in developing countries may impose a heavy burden on society. A rapid increase in numbers implies an accelerated growth of virtually all needs and there is no reason to assume that the larger number will by itself increase the productive capacity sufficiently to compensate for the faster growth of population. Under the assumptions of most analytical studies and models, growth of income would be faster, the slower the growth of population. These findings, however, are not completely corroborated by the available empirical findings. Country data show no consistent association between the rate of growth of population and the rate of growth of total product during the 1950s and 1960s. The fact that many developing countries have achieved substantial growth of total product, and even gains in *per capita* product, indicates that rapid population growth does not preclude economic improvement. While the rate of population growth may not be one of the predominant factors determining the rate of economic growth, there appears to be a consensus that high population growth rates have held back advances in levels of living and have caused a widening of the income gap between developed and developing countries.

#### 6. NEW CONCERN WITH POPULATION POLICY

31. Among the most significant phenomena of the 1960s was the proliferation of national population policies that reflected the concern of Governments with the consequences of accelerating population growth.<sup>8</sup> In the 1930s when questions of population had also commanded much attention, it was the fear of declining population in the industrialized countries that provided cause for alarm.

32. In the early 1950s economic development for the world's less advanced agricultural countries became an accepted goal in the international community. The late 1950s saw a reconsideration of the role of social factors in human development, leading to an international consensus of opinion that social policies ought to be an integral part of national development policies. The second half of the 1960s introduced another dimension of the development process, namely the inclusion of population and population policies. Acceptance of this demographic component of development gained momentum and, by 1970, Governments of countries having more than half of the world's population had declared themselves in favour of policies aimed at influencing population growth. Government action in this field was accompanied by intensive study on the part of technicians of the means

<sup>8</sup> There are at present a few developing countries of sparse population where population increases are considered desirable to reduce overhead costs of certain infrastructure investments, if not also for other reasons.

of implementing official policies, and much attention was devoted, for example, to problems related to the organization, equipment and administration of large-scale family planning programmes.

33. While it is perhaps premature to speculate about the consequences of this new emphasis on population policies, it seems clear that there is a new awareness in the world of the important role of population factors in development, and that there has been a gradual change in opinion and in basic philosophy with respect to population questions. Appreciation of the significance of the population changes that are expected to occur during the next decades has stimulated scientists to promote relevant research needed to deal with the problems these demographic trends are likely to raise. While many of these problems call for an intensification of economic and social development programmes, it seems likely that the further development and refinement of population policy will become a feature of planning in both developed and developing countries during the coming decades.

#### 7. THE DEVELOPMENT OF DEMOGRAPHY AS A SCIENTIFIC DISCIPLINE AND ITS RELATION TO OTHER DISCIPLINES

34. In spite of the early scientific efforts of demographic pioneers, such as Graunt and Petty, and the early interest of economists in population matters, progress was not continuous. Like the other social sciences, demography has tended to develop, at least in part, in response to existing conditions or problems and thus progress was uneven. The emphasis given during the nineteenth century to mathematical, biological or other aspects of population trends hampered the formation of consistent and integrated theories in relation to which applied research could unfold. The largely statistical orientation of population studies in the beginning of the twentieth century was encouraging, though insufficient. Thus, many components of this scientific discipline remained to be established in order to make demography a partner of other sciences on an equal footing.

35. Several important steps in this direction occurred during the 1950s and 1960s. The propositions of the demographic transition were reconsidered, causes of rapid population growth were studied, and partial theories were offered to explain the variables affecting fertility, the process of urbanization and the like. New concepts and terminology were introduced into the study of population. Development of a standard terminology by the International Union for the Scientific Study of Population culminated in the publication of the *Multilingual Demographic Dictionary*,<sup>9</sup> thus reinforcing the international character of population studies. In the early 1950s there were only three specialized technical periodicals on demography, but by the late 1960s their number had grown considerably. National and international conferences, and particularly the 1954 and 1965 World Population Conferences, have stimulated the integration of international experience and international theoretical approaches into a more systematized body of knowledge. Gradually, demography became institutionalized as an academic

<sup>9</sup> United Nations, *Multilingual Demographic Dictionary* . . . (1958).

discipline in a number of universities and autonomous institutes. By the early 1970s there were a number of national demographic research institutes dedicated to impressive programmes of research in general or specialized areas of demography.

36. The teaching of demography at many universities was another factor which contributed to its development as a science. According to a UNESCO study,<sup>10</sup> in the early 1950s demography was taught in most parts of the world either as a part of demographic statistics, or as a subordinate field either within the departments of sociology or economics. Currently there are several countries in which demography has become a major subject of post-graduate courses leading to higher degrees.

37. Recognition of the interdisciplinary character of population phenomena and the growing interest in their study has led to new orientations in a number of scientific disciplines. The study of population within economics, neglected for a number of decades, has undergone a renaissance. In relation, particularly, to the problems of economic development of the third world and to development planning, population has become a prominent subject area within economics. A number of topics, such as population and development, manpower studies, the economics of fertility, and more comprehensive economic-demographic models, were developed in an attempt to better understand the interrelationships between population trends and economic growth.

38. Sociology, which in some countries had paid significant attention to demography, recently has been influenced by new tendencies in population studies. Family formation and fertility became a subject area of great interest, as did the interrelations between population change and social change in the broadest sense. Sociology has also contributed substantially in the fields of urbanization, migration and patterns of spatial population distribution. Social psychology, psychology and other behavioural sciences have discovered a new area of research in the complex and intricate set of questions connected with family planning, the reproductive behaviour of individuals and the social standards or cultural norms governing the behaviour of individuals.

39. Population geneticists were encouraged to pursue the study of human populations by a number of questions raised by biologists in demographic terms. In addition, reproductive physiology made a significant contribution to a better understanding of the reproduction of human populations. Applied research led to significant improvements in contraceptive technology and opened new perspectives towards more rational regulation of human fertility.

40. Even in some areas in which population had traditionally been regarded as a marginal subject, it has been receiving greater attention during the past two decades. Regional studies and city planning gave increasing emphasis to the study of the geographic distribution of population and of movements between rural and urban areas. Significant research has been initiated in such an

unexpected area as population and law in an attempt to examine the effect of legislation and legal institutions on population in general, and on the practice of birth control in particular. More recently, ecology and environmental science has focused on population questions with the aim of elucidating such basic issues as the effect of population growth on environmental factors, or in an attempt to promote policies necessary to prevent pollution.

41. With the growing importance of population in the social sciences in general, there has been a new trend in those disciplines which include an implicit humanistic orientation. Increasingly, questions have been raised of human rights and the status of women, particularly in connexion with the question of fertility regulation. Increased emphasis has also been given to those aspects of population trends which are international by their character and consequently affect the international political order. In a comprehensive reappraisal, which appears to challenge all the premises and guiding hypotheses relative to population growth, there are also new attempts to scrutinize the most fundamental relationships between population growth, economic development, social and environmental change and other factors ultimately affecting the well-being of nations and individuals. A number of hypotheses have been proposed, although there are still no comprehensive philosophical or ethical studies relative to this complex and delicate area.

## 8. GAPS IN KNOWLEDGE

42. The studies and research summarized in the present volume show the impressive growth of knowledge about human population and related social and economic problems in the past two decades. As a result of this expanding knowledge, nations have initiated new policies and programmes which are perhaps more enlightened than those of the past. Despite significant advances, however, the knowledge of population and its economic and social correlates is still deficient. On the occasion of the first World Population Conference in 1954, attention was called to the different dimensions of the gaps which still existed in the knowledge of demographic, economic and social interrelationships. These included the inadequacy of statistical data; the over-simplification or obsolescence of demographic theory; the limited ability to predict demographic consequences of particular economic and social changes, and even less ability to predict economic and social consequences of population change, or to trace a sequence of interrelated demographic, economic and social changes.<sup>11</sup>

43. These gaps, which existed in the 1950s, are only partly filled by the findings of recent research. Imagination and vision have not yet penetrated into the intricate web of individual and socio-cultural behaviour to determine the basic nature of their interactions with economic growth and social progress. The statistical data which are indispensable for analyses and conclusions are still inadequate for large areas of the world. It is not known to what extent generalizations based on empirically

<sup>10</sup> United Nations Educational, Scientific and Cultural Organization, *Demography ...* (1957).

<sup>11</sup> United Nations, "Economic and social implications ..." (1955), p. 176.

established facts in some areas of the world can serve as assumptions and hypotheses for far-reaching conclusions in other areas for which facts have not yet been established. The recent valuable contributions to demography and related sciences have given new insight into some crucial aspects of demographic, economic and social interplay, but have also led scholars to be aware of the still considerable shortcomings of knowledge.

44. These deficiencies in knowledge are found in all the major areas of demographic, economic and social relationships. While a systematic assessment of gaps in knowledge has not been possible in the present study, some examples may illustrate the nature of the problems that still remain. It has not been possible, for instance, to determine the relative influence of different economic and social factors which contributed to the long-term decline of fertility in the now industrialized countries. Nor have satisfactory explanations been found for the fact that fertility differences exist among the developing countries that do not appear to be related to the level of economic development. The conditions conducive to fertility decline in developing countries are not known with sufficient precision. For example, what kind and how much education is required to initiate important changes in attitudes towards family size and motivation with respect to reproductive behaviour? Through what processes does such change operate to influence individual motives in this sphere? Can couples be successfully motivated to adopt small-family patterns in the absence of a significant measure of other social change in the society? Another area requiring much further research is the development of methods for measuring the contribution of family planning programmes to fertility decline. The economic benefits of such programmes in relation to their costs is likewise an insufficiently explored subject at present.

45. While there are thus many serious gaps in knowledge still remaining with respect to the factors affecting fertility, this field has been much more intensively studied in recent years than other branches of demography, owing to its key role in determining future trends of population growth. In comparison with the recent attention given to fertility analyses, certain other aspects of population change have been relatively neglected. This applies in particular to the study of nuptiality, the processes of family and household formation, and to certain aspects of mortality. One of the main obstacles to improvement in the forecasting of probable future mortality trends is the poor quality of information on cause of death, even for the more developed countries. The relationship between infant mortality and fertility has not been very well established. Satisfactory methods for measuring health and morbidity have not yet been developed, and therefore no assessment is possible at present of the comparative general health status of different populations. With respect to mortality trends in developing countries, there are hypotheses, but no firm evidence, as to how far mortality decline might proceed through the application of modern technology alone in the absence of significant improvement in the level of living.

46. Migration statistics being among the most deficient of demographic data, no sound basis exists for determining the annual net balances of international migration

in many countries. While the majority of modern migrations have their roots in economic causes, there have been few attempts to assess the net effect of economic costs and benefits accruing to countries of immigration and emigration. Although the "brain drain" has been a much discussed phenomenon of the post-war period, its impact on the development efforts of those countries which have lost substantial numbers of their highly qualified personnel through migration has not yet been adequately appraised.

47. While the effect of demographic trends on economic development is a subject of much concern, the relationship is a complex one involving so many interdependent factors that it has not proved possible to isolate the demographic influences. Because of the key role of productivity in economic development, further research on the relationship of population size, its rate of growth and structure to the various determinants of productivity, assumes special importance. However, systematic study of the relationship of demographic trends to the many factors influencing productivity—for example, methods of production, specialization and economies of scale, skills of the labour force, advances in technology etc.—is not yet far advanced. Likewise, relatively few hypotheses and models have been established to explain the inter-relationships among population, education and economic development.

48. While there have been a number of attempts to study the effects of rising income and education on labour force participation, these relationships require further exploration. Whether the labour force is likely to expand or contract during periods of economic depression and what effect economic development is likely to have on the size of the female labour force are also far from clear. There are theories, but little empirical evidence, of the relationships of age of workers to the efficiency of the labour force. No satisfactory methods have yet been developed for measuring invisible underemployment arising from inadequate earnings or underutilization of a worker's skills.

49. These are but a few examples of the still remaining gaps in demographic knowledge. A comprehensive inventory of these gaps and lacunae remains to be drawn up and programmes of research developed with the aim of further reducing the areas of ignorance. Such programmes must take into account the present state of knowledge as well as the prospects for development of various disciplines concerned with population. For instance, aspects of population trends which might lead to international consensus regarding future national and international policies clearly deserve much attention. Another area worthy of high priority is the question of coordinating population policies considered desirable for the general welfare with individual aspirations and ideals with which the former may be in conflict. This is an interdisciplinary concern, involving also the active engagement of the political sciences.

50. The basic question of the interaction between science and government will, no doubt, affect the future of demography and related disciplines. A number of pertinent questions come to mind. Is the scientific community ready to make the necessary efforts to facilitate the development of appropriate policies by Governments?

Are the Governments ready to consider the advice of experts while evolving and developing their national policies? Have individual nations and the international community reached the stage of maturity which enables them to consider and decide upon the vital issues of the world *sine ira et studio*? The answers to these questions may determine whether the future progress which can be expected in view of the experience of the last two decades is accelerated or retarded.

## B. Organization of the study

51. The organization of the revised edition of *The Determinants and Consequences of Population Trends* differs substantially from that of the 1953 edition and reflects some of the major developments in the field of population described earlier in this chapter. At the beginning of the volume, chapters on the history of world population growth, population theory, fertility and mortality follow along the lines of the earlier edition. In a departure from the previous edition, international migration has been separated from internal migration; trends in the former, as well as their causes and consequences are discussed in chapter VII, while the latter is one of a number of major subjects discussed in chapter VI.

52. The revised edition contains new chapters dealing respectively with demographic aspects of modern economic growth, demographic considerations in planning and population policies—all subjects which have come into prominence in the past two decades. The crucial relationship between food supply and population is the subject of a separate chapter in this volume, whereas in the earlier edition it was included in a chapter on the relationship between population and resources in general. A separate chapter in the present study is also devoted to the findings of demographic studies on families and households, a previously neglected area of research. In recognition of the increasing importance of urbanization as a demographic phenomenon and the vast expansion of relevant literature, this subject, which received relatively little attention in the 1953 edition, is discussed extensively in chapter VI. Several different types of demographic—economic relationships which were discussed in different chapters in the first edition, have been brought together

in chapter XIII of the new edition; this chapter treats the subjects of demographic aspects of savings, investment, employment and productivity. While other important aspects of population change and their implications undoubtedly merited consideration for inclusion in the present study, there are inevitable limits to such a publication and certain subjects originally scheduled for coverage had to be omitted.

53. A summary such as that provided in the present study, covering a broad range of subject matter, cannot include mention of all relevant books and articles on each of the topics discussed. It has been the aim to include references to a selection of studies, which in so far as possible, would be representative of works carried out in all parts of the world and of differing points of view. Despite the special efforts which were made to ensure a fair representation of works in all languages (as detailed in the preface to this volume), it is acknowledged that this goal has not always been attained. The sources cited in each chapter reflect the range of material available to the United Nations Secretariat and to the individual authors who collaborated with the United Nations in the preparation of the texts. Undoubtedly many scientific works of merit have escaped attention. In cases where numerous studies dealt with the same subject, examples have been selected to illustrate the principal findings. In such cases the choice of examples is not to be construed as an expression of judgement as to the relative value of different works.

54. In the preparation of the present volume, some older material in the 1953 edition had to be eliminated in order to make room for more recent studies. Since the present volume was in preparation for a number of years, some chapters were completed much earlier than others. Hence, mention of works completed in very recent years occurs with greater frequency in those chapters which were last to be completed.

55. Throughout the study an effort is made to distinguish between conclusions that are generally accepted and based on well-established facts and those partly dependent upon authors' interpretations of facts, or containing a large element of opinion. Where the findings of different studies are in conflict, an attempt has been made to present the different points of view impartially.

## Chapter II

### HISTORY OF WORLD POPULATION GROWTH

1. In the scale of the hundreds of millions of years through which range speculations as to the beginnings of various expressions of life, man has but recently appeared. According to one representation, if these aeons were transposed to the relative time span of one year, the appearance of *Homo sapiens* would take place at approximately 2000 hours on the last day of the year, with the neolithic age beginning slightly less than five minutes before midnight.<sup>1</sup>

2. A continuous average increase of slightly less than 0.02 per cent per year would have produced the present population of the world from two dozen individuals a hundred thousand years ago. It is certain, however, that the secular trend of man's increase at no time proceeded at a constant rate, but was interrupted by periods of decline and at other times quickened its pace. It is in the modern period that the highest rates of growth have been sustained, with marked acceleration evidenced only in the twentieth century. It is likely that to the more than 3,000 million inhabitants of the earth in 1960, approximately 600 million, or roughly twice the number thought to have been in existence at the beginning of the Christian era, will be added in the succeeding decade. Although even at the present date the estimated numbers of inhabitants of large parts of the world are seriously questioned and for the remote past they are necessarily afflicted with greater uncertainty, the probable orders of magnitude shown in table II.1 give some indication of the dramatic multiplication of mankind.

3. Man's mastery of the often hostile physical elements of his surroundings permitted his existence as a species in the first instance, and his propagation in the second. His evolution has been a response primarily to the necessity to satisfy basic needs: food, shelter, clothing. As their acquisition increased his comfort and security and a surplus afforded opportunities for the cultivation of abilities and talents, aspirations were refined. An increasing ramification gradually appeared in the social structure, the element which promises today to become of surpassing import with the gain in control over the economic mechanism.

4. In the distant past, an improved food supply that alleviated malnutrition and lessened the incidence of famine is generally credited with having given an impetus to the first slow increment of the earth's inhabitants. Conversely, an expanding population could impel a community to improve methods for its sustenance.<sup>2</sup> The

TABLE II.1. CONJECTURES OF HISTORICAL POPULATION GROWTH

Date	Population (millions)	Average annual increase (per cent) since preceding date <sup>a</sup>	Approximate number of years required for population to double at given rate

SOURCES: see paragraphs 11, 30 and 56, and table II.4 below; estimates for 1950, 1960 and 1965 from United Nations, *World Population Prospects as assessed in 1968* (to be issued as a United Nations publication) (1970).

<sup>a</sup> Rates for periods prior to 1960-1965 are calculated on the basis of population at mid point of range.

beginning of the trend of increasing numbers early in the modern period has been linked to the initiation of social and economic advance. While in modern times the severity of the challenges to population growth has moderated, the complexity of factors affecting demographic trends has increased. To answer the many questions concerning these trends, a greater interdisciplinary co-operation among scientists has been recommended.<sup>3</sup> In attempting to outline the historical pattern of world population movements, this chapter draws upon the limited statistical data that have been compiled, in many instances not designed for demographic purposes. Where these data were lacking or patently inadequate, the work of archaeologists, anthropologists, geographers, economists, historians and numerous scholars in related fields has been the basis of deductions and amplifications.

#### A. Palaeolithic to early historic period

5. Palaeontology and archaeology are the principal contributors to the study of earliest man, more significantly since the introduction of carbon-dating, the technique which in many instances is able to reinforce estimates

<sup>1</sup> Nougier, *Géographie humaine préhistorique* (1959), pp. 14-15.

of the chronology of prehistoric events where long lapses of time are in question. Another method of arriving at inferences about the nature of prehistoric life is by the investigation of primitive societies extant, such as is conducted by anthropologists. Dating of geologic strata and deductions as to geographic conditions are further aids to understanding influences on the development of early populations.

6. Climate has been said to have exerted a major fundamental influence on human development.<sup>4</sup> During the course of the millions of years required for the evolution of the primates, it appears that man emerged as the dominant species during the geologic period of the Pleistocene, which began about 600,000 years ago. The greatest of the four separate glaciations which characterized this period covered about one third of the earth's land surface with ice at its most extensive phase.

7. The first stone-age industry was the means of at once increasing primitive man's food supply. The prolongation of life which resulted was not the only factor in increasing the population. It has been postulated that important to man's development into a single species was the quicker multiplication of the more successful types and the probability that they absorbed rather than extinguished rival species.<sup>5</sup> Leakey sees a more significant effect of the lengthened life span as permitting favourable mutations in the species to be reproduced at an accelerated rate.<sup>6</sup>

8. Ancestors of modern man seem to have become distinct from other lines of hominoids at least some 12-14 million years ago.<sup>7</sup> Skeletal remains considered as belonging to the genus *homo* approximately one-half million years old have been discovered in Java, China and other parts of Asia, and in Europe.<sup>8</sup> The oldest of such remnants, found at Olduvai Gorge in Tanganyika in association with stone tools and dating from about 1 million years ago, give weight to theories that it was in Africa that near-man advanced to the status of man by fashioning tools to a set and regular pattern.<sup>9</sup> Man's essentially biologic evolution may have been virtually completed at least 100,000 years ago. Around 50,000 years ago, following the gradual extinction of various collateral lines, such as Neanderthal man, *Homo sapiens* became established as a single species.<sup>10</sup> His evolution thereafter proceeded along cultural paths.

9. In addition to fashioning tools, man early mastered the use of fire, which further extended the range of his diet and habitation, encouraged closer group life and later made metallurgy possible. Hearths uncovered by archaeologists give evidence that the hunting and gathering

economy did not necessarily demand perpetual migration. Governed by a first principle of settlement geography, primeval man would have located where water and natural shelter were provided and food could be found within a convenient radius, thus becoming part of a community, of "a biologic and social group, clustering about hearths at the point of least transport, holding a collecting territory for its exclusive use, and relocating itself as infrequently as necessary".<sup>11</sup> The long period of infantile helplessness and maturation encouraged a more sedentary way of life. Children in such an economy were more of a handicap than in an agricultural economy and there are indications that infanticide was widely practised.<sup>12</sup> There is no sign of promiscuous mating; for economic reasons, monogamy was apparently the rule.<sup>13</sup> Remnants of the oldest known dwellings, uncovered at Vestonice in Czechoslovakia, show they were constructed and inhabited in the course of the upper palaeolithic period.<sup>14</sup>

10. Nevertheless, migration in small bands long predominated over settlement as a population characteristic and, as adaptation to changing conditions permitted, palaeolithic man spread over Africa and Eurasia. It is believed that humans first appeared in America as immigrants, crossing over a presumed land bridge at the present Bering Strait in the neighbourhood of 20,000 years ago,<sup>15</sup> possibly during one of the periods when climatic conditions were less severe in northern latitudes than they are now.

11. Throughout the world, desert and recurring ice conditions isolated some groups for millennia. The density of these primitive hunting and gathering peoples varied widely according to different conditions. When Australia was first settled by Europeans in 1788, the aboriginal population is estimated to have been about 300,000 with densities of from 2.5 to 5 persons per square kilometre in the favourable coastal or river-valley areas and about 1 person per 80 to 100 square kilometres elsewhere.<sup>16</sup> When purchased by the United States, Alaska had an average population density of approximately 1 person per 65 square kilometres, while that of the Northwest Territories was about 1 person per 500 square kilometres. Conditions in those areas and the most severe in late glacial Eurasia may have been roughly analogous.<sup>17</sup> It is reasonable to assume greater densities in more southerly regions, particularly in Eurasia. In the presumably highly favourable conditions of the Egyptian region of the Nile, a population of 20,000 at the most

<sup>14</sup> *Ibid.*, p. 134.

<sup>15</sup> Müller-Beck, "Paleohunters in America ..." (1966), p. 1,207, places the occurrence of this event from about 26,000 to 28,000 years ago.

<sup>16</sup> Mulvaney, "The prehistory of the Australian aborigine" (1966), p. 84. The author reasoned that the lack of tusked animals and scarcity of fine-grained rock were limitations on the tool industry and therefore on securing the abundance of food that would support a growing population, p. 85. Kroeber, *Anthropology* ... (1948), p. 390, has suggested a density of twenty-five persons per hundred square kilometres for the hunting-gathering areas along the Pacific coast of North America from Alaska to California.

<sup>17</sup> Hawkes, "Prehistory" (1965), p. 120.

has been suggested for the end of the palaeolithic period.<sup>18</sup> That number in the cultivated area of the United Arab Republic around 1960 would amount to an average of approximately 1 person per 2 square kilometres. It has been estimated that about 50 million square kilometres of the earth were usable as the Pleistocene was ending, and that on an average at least 5 square kilometres per person were required to sustain the human population. This has suggested a maximum world population of 10 million,<sup>19</sup> with the possibility that it was as low as 5 million.

12. Analyses of fossil remains confirm that the life of prehistoric man was short and frequently ended in violent death. Those who lived in a harsh environment died younger; those in more favourable circumstances lived longer. Physical environment alone, however, did not cause early death; cultural factors also played a part, and the observation that "one of the main causes of death of early man was his being killed by his own fellow-man"<sup>20</sup> likely had relevance throughout prehistory. The possibility is entertained that duration of life may have lengthened slightly in the neolithic age,<sup>21</sup> when food was more plentiful, although in an agricultural society famine and epidemic more often than war caused sudden peaks in the death rate.

13. Few skeletons of infants have been found preserved from early periods, but it is believed that infant and child mortality was extremely high. The slight evidence available suggests that most adult deaths occurred between ages twenty to thirty years, with women dying at a younger age than men as a rule. Some studies have led to estimated crude death rates ranging from 50 to 80 per thousand in the palaeolithic period, and a life span for men about 20 per cent longer than that for women.<sup>22</sup> It appears that this sex-differential in mortality was general almost until the modern era.<sup>23</sup> Conclusions that survivors to adult ages rarely attained the age of fifty may find some support in findings at the excavated Anatolian neolithic village of Çatal Hüyük. Remnants of food, artifacts and build-

ings dating from the sixth millennium indicated a high degree of accomplishment, and the human skeletons were those of a healthy population; nevertheless the life-span of the inhabitants was short.<sup>24</sup> It has been tentatively suggested that even in the Iron Age in France, average expectation of life at birth was no more than ten to twelve years, which would have required crude birth rates to be over eighty per thousand if the population were to survive.<sup>25</sup> It seems that mere maintenance of the species in normal conditions would have required a minimum of three female births per woman attaining her reproductive period, given the following assumptions: a mean expectation of life of twenty years, infant mortality of about two thirds and, of the hypothetical total of six births, the survival to adult years of one female capable of bearing children. In actuality, the reproduction rate would have had to be well above this level to offset losses during periods of greater-than-usual hardship.

14. The level of mortality, governed in the past by the degree of hardship in living conditions and to a great extent in recent times by the improvement of conditions directly related to health, has been emphasized by some as the primary determinant of population increase or decrease.<sup>26</sup> The birth rate is given equal weight by others, who consider that even in early times indications of fertility control by means of abortion, sexual taboos and marriage customs signified a modification of attitudes favouring maximum child bearing.<sup>27</sup> The concept of fertility as a demographic variable, not a biologic constant, would therefore seem to have applicability throughout all times.<sup>28</sup> Fecundity may be viewed in a similar light, considering the effect of individual differences with respect to the number of years reproductive capacity is effective, its rate of diminution, and the instances of total infecundity.<sup>29</sup> It is generally concluded that there has been no change in the basic fecundity of the human species. However, the possibility of a greatly varied incidence of infanticide should be included in these considerations.

15. The evolution from a hunting and gathering economy has been accomplished in perhaps only the last 1 or 2 per cent of the duration of human existence by even the most advanced of today's societies. During a geologic period of extreme instability of climate and also of extreme simultaneous climatic contrast, modes of securing subsistence were spread by migration of peoples and cultural diffusion, and adapted to conditions in

(1963), pp. 633-645. The frailty of conclusions based on prehistoric skeletal remains is discussed by Henry, *Commentaire* [to Nougier, "Essai sur le peuplement..."] (1954), pp. 272-274.

<sup>23</sup> Goldstein, "Some vital statistics..." (1953), pp. 3-4, found that skeletons, dating from about A.D. 800 to 1700 of American Indians, whose culture was comparable to those of earlier stone-age peoples in other regions, indicated an average life span of thirty-one years for one group of 767 individuals and forty-three years for 587 from another locality. In so far as could be determined, males generally outlived females. A study by Jones, "The demography of the Australian aborigines" (1965), pp. 232-245, finds a reversal in this sex-differential for present-day Australian aborigines. Living under immeasurably more favourable conditions than their remote ancestors, they show an estimated expectation of life at birth of 50 for males and 50.7 for females.

<sup>24</sup> Mellaart, *Çatal Hüyük...* (1967), particularly p. 225.

<sup>25</sup> Nougier, "Essai sur le peuplement..." (1954), p. 267. It was noted that death rates may have been lower in the preceding neolithic era.

<sup>26</sup> Thompson, "The spiral of population" (1956), p. 975.

<sup>27</sup> Durand, "World population..." (1958), pp. 31-32.

<sup>28</sup> Taeuber, "Future population trends..." (1966), p. 192.

<sup>29</sup> Briefly stated, "fertility" refers to procreative performance, "fecundity" to procreative potential. This difference is discussed in detail in chapter IV. Bourgeois-Pichat includes a consideration of fecundity in his "Social and biological determinants..." (1967), pp. 160-163, and finds wide variations in fertility a characteristic of pre-modern societies.

widely separated locations.<sup>30</sup> While the earliest stone-age industry was probably of African origin, it appears that its subsequent development and the related cultural expansion, as interpreted from artifacts and drawings on cave walls, apparently received the greatest impetus in the Mediterranean region, and South and East Asia.<sup>31</sup>

16. The first great economic revolution—the development of agriculture and the domestication of animals—ushered in the neolithic age.<sup>32</sup> Present knowledge places its origin in the hills of South-West Asia about 10,000 years ago, following the final retreat of the glaciers and the cessation of the pluvial periods. There was a significant change in the physical environment at this period. Prairies south of the Mediterranean and in South-West Asia became more desiccated and were traversed by great rivers and interspersed with oases. The wind-swept interior plains became hard grass lands; great forests spread across much of Europe, northern Asia and North America. Although almost nothing is known of the beginnings of this “neolithic revolution”,<sup>33</sup> there is some conviction that it was preceded by changes not only in the natural conditions of the environment, but in the level of culture as well.<sup>34</sup> No evidence has yet been uncovered to support the hypothesis that there may also have been a separate point of origin in South-East Asia,<sup>35</sup> but the later innovation of agriculture in Middle America seems to have taken place independently.<sup>36</sup>

17. One of the earliest agricultural settlements yet uncovered, Jarmo in Iraq, dating from about 7000 B.C., appears to have had about 150 inhabitants. Estimated average population density for the settled portions of the area, about 10 per square kilometres, has remained roughly the same to the present day.<sup>37</sup> This more seden-

tary way of life and greatly augmented food supply at once encouraged increases in populations which had heretofore had only a precarious tenure on existence.<sup>38</sup> When densities grew beyond the carrying capacity of the site, the excess numbers formed new settlements flourishing first in the Fertile Crescent;<sup>39</sup> their probable size has been put at from 200 to 500 inhabitants.<sup>40</sup>

18. There was a further diffusion of agriculture and the industries it stimulated and supported into the Near East, Central Asia, Africa, and Europe along the sea coasts and deep into the continent by way of such river valley systems as the Dnieper, the Danube, and the Rhone. By about 1500 B.C. in Europe, only the northern forest of the Scandinavian peninsula and the Russian forest and *tundra* remained untouched by it. Its effect on human multiplication is suggested in a study based on archaeological evidence for the area comprising present-day France. A maximum of 50,000 inhabitants was estimated in the final stage of the palaeolithic period, followed by decline until the beginning of the neolithic age. By the fourth millennium, the first agriculturists and forest-dwellers possibly numbered one-half million; in the next thousand years, growth to five million is considered plausible.<sup>41</sup> Clusters of dwellings uncovered in the Danubian culture region suggest villages in the range of 200-600 inhabitants, settlements representing “a quite revolutionary growth . . . where only a few tiny bands of hunters had previously roamed”.<sup>42</sup>

19. Increasing complexity was expressed in political organization, new institutions, a stratified society.<sup>43</sup> Advances in agriculture and related technology produced food surpluses sufficient to maintain communities of those who did not grow their own food and therefore could specialize in other activities.<sup>44</sup> The social structure of the first small towns in the fertile alluvial plain of Mesopotamia lent itself to economic development,<sup>45</sup> which in this locale took the form of large-scale irrigation and flood-control systems that made possible vastly greater crop

<sup>30</sup> Sauer, “The agency of man . . .” (1956), pp. 51-54. Hulse succinctly summarizes the historic significance of migration in stating that men everywhere tend to spread their genes, their ideas and their artifacts, given the opportunity, and that none of these are transmitted by telepathy. Hulse, “Comment” [on Newman, “A trial formulation . . .”] (1958), p. 41.

<sup>31</sup> Leakey, *The Progress and Evolution . . .* (1961), p. 10.

<sup>32</sup> Cipolla, *The Economic History . . .* (1967), p. 18.

<sup>33</sup> Childe, *Man Makes Himself* (1965), uses this term in the sense that certain conditions, as the culmination of a gradual process, were analogous to those of the “Industrial Revolution” in Europe, i.e., in particular, a sudden increase in population (see chapter V).

<sup>34</sup> Braidwood, “The agricultural revolution” (1960), p. 134, giving weight to cultural development, states that there was not a significant change in climate in the area where farming appears to have originated. Sauer, “The agency of man . . .” (1956), p. 56, sees the origins of planting and domestication in a previous sedentary society, having a surplus and leisure. See also Vidal de la Blache, *Principes de géographie humaine* (1948), pp. 74-111; Brunhes, *La géographie humaine* (1956), pp. 300-310.

<sup>35</sup> This hypothesis is discussed in von Wissmann *et al.*, “On the role of nature . . .” (1956), pp. 285-286, with particular reference to the investigations of Smolla.

<sup>36</sup> MacNeish, “The origins of new world . . .” (1964), pp. 29-37, dates domesticated food c. 6700 B.C., domesticated animals c. 3400 B.C., as well as the first fixed settlements, in the valley of Tehuacán in Mexico where there is the longest known record of continuous occupation in the New World.

<sup>37</sup> Braidwood, “The agricultural revolution” (1960), pp. 136, 138-143. Other discoveries of this period are Jericho—see Kenyon, *Archaeology in the Holy Land* (1960)—and Çatal Hüyük in Anatolia—see Mellaart, *Çatal Hüyük . . .* (1967).

<sup>38</sup> Mumford, *The City in History . . .* (1961), p. 11, suggests “... the extra security . . . the relief from forced fasting, that long-proved diminisher of sexual appetite, may have given to sexuality . . . an early maturation . . . a potency it perhaps lacked in the anxious, often half-starved life of hunting and collecting peoples”.

<sup>39</sup> Childe, *New Light on the Most Ancient East* (1952), pp. 122, 232-233. The author dates this early growth about 4000 B.C.

<sup>40</sup> Adams, “The origin of cities” (1960), p. 154.

<sup>41</sup> Nougier, “Essai sur le peuplement . . .” (1954), p. 269.

<sup>42</sup> Childe, *The Prehistory of European Society* (1958), p. 50. The author states that the colonization of this vast central European territory was accomplished by reason of the fertility of the peasants and an economy principally dependent upon vegetable crops which quickly exhausted the soil. The villagers were then forced to move to a new site when all plots within walking distance were rendered infertile, pp. 49-53.

<sup>43</sup> Sjöberg traces the development of urbanism in the context of cultural analysis. See his “The origin and evolution of cities” (1965), pp. 25-39; also *The Pre-industrial City* (1960).

<sup>44</sup> This feature is generally accepted as the prime criterion for the differentiation of rural and urban sectors of society. See Davis, “The origin and growth of urbanization . . .” (1955), pp. 429-430.

<sup>45</sup> Childe, *New Light on the Most Ancient East* (1958), pp. 118-119. It is inferred from the prominence of the temple in very early sites that religious beliefs and ceremonies were under the control of full-time priests, who required the support of the farmers.

yields. It is widely held that the collective activity required in the regulation of water and soil resources enlarged the political, economic and cultural base and provided for an accelerating human multiplication at a high density level.<sup>46</sup> By about 4000 B.C., what has been termed the second great revolution in human culture, the "urban revolution", had begun, described as "... an expression more of changes in man's interaction with his fellows than ... with his environment".<sup>47</sup> It apparently began more or less simultaneously in two oases—the Lower Nile region and Lower Mesopotamia—marking the end of a passage of 3,000 or 4,000 years in which "the life of man had changed more radically than in all of the preceding 250,000 years".<sup>48</sup> Recent discoveries indicate that the Harappan civilization flourished concurrently with the Sumerian and the early Egyptian, and that it extended far beyond the Indus valley, even reaching the present border between Iran and Pakistan, the Himalayas to the north and along the west coast of India to the Gulf of Cambay north of modern Bombay.<sup>49</sup> Somewhat later, the Hwang Ho (Yellow River) Valley provided the early centre of expanding civilization in China, and in the first millennium, Mayan civilization emerged in Middle America.

20. Conjectures as to the size of early cities cover a wide range. Where archaeologists have been able to gauge the area of ancient sites and the type and proximity of dwellings, an assumed average density may indicate the number of inhabitants. Estimates of the labour required to erect the characteristic monumental structures, written records on clay tablets and extent of cemeteries are among the clues considered in dispelling some of the mystery. The city-states of Sumer were an outgrowth of the need to administer its system of irrigation agriculture, and those with a situation favourable to commerce and industry expanded accordingly. Recent excavations at Uruk suggest a population of 50,000 about 2500 B.C.<sup>50</sup> Remains of the great capital city of Ur suggest that the built-up area may have comprised a population of around

200,000 early in the second millennium,<sup>51</sup> while the uncovering of a provincial city of that time indicates it had about 9,000 inhabitants.<sup>52</sup> Thebes, as the capital of Egypt, could have had around 225,000 inhabitants about 1600 B.C.<sup>53</sup> However, for this initial period of urban development it has been judged that the number of cities did not increase significantly and that in general their size remained in the scale of 2,000 to 20,000 inhabitants until well into the first millennium.<sup>54</sup> One reason for this lack of growth may have been the static condition of technology until after iron first came to be used in the Near East, about 1300 B.C.<sup>55</sup>

21. In the ancient domains, technical and economic advance included the development of metallurgy, the introduction of writing systems, and the elaboration of handicraft, commerce and the division of labour. More complex political systems and new modes of construction were also introduced. The relation of city-centred civilizations and the more primitive farming societies remains obscure. Technical advances presumably were complementary in these societies, stimulating the growth of population both in the urban civilizations and in rather distant primitive communities.<sup>56</sup> Thus, a fairly continuous area of increasing population density extended across North Africa and Southern Europe, and Southern Asia and in isolated areas of Eastern Asia as well. There were, nevertheless, great regional differences, accentuated by frequent calamities, warfare and shifting centres of political control. These trends reached temporary culminations in the Seleucid and Sassanid Empires in Persia, Asoka's Empire in India, the Han Empire in China and in the Roman Empire in the Mediterranean basin, all within a few centuries before or after the beginning of the Christian era.

22. Where the frontiers of agricultural society were not marked by forest but by steppe or desert, the consolidation and expansion of farming communities gave rise to pastoral nomadic societies, notably in central and South-West Asia and North Africa. Recurrent invasion by such nomads and by forest dwellers constituted a persistent pressure on the early empires of antiquity, and strong frontier tensions of this kind remained a slowly diminishing check to the expansion of settlement, and probably of population growth, until recent history.<sup>57</sup>

<sup>46</sup> Wittfogel has estimated that in the 3,000-4,000 years prior to the growth and expansion of population associated with the Industrial Revolution, 60 to 70 per cent of the world's population lived under conditions shaped by hydraulic civilizations. See Thomas, ed., *Man's Role* ... (1956), p. 418. See also Adams, "The origin of cities" (1960), p. 157; Woolley, "The beginnings of civilization" (1965), pp. 415 ff.

<sup>47</sup> Adams, "The origin of cities" (1960), p. 153. Childe places this event in a unilinear historic development, *Man Makes Himself* (1965). Wittfogel, "The hydraulic civilizations" (1956), pp. 152-164, first classifies societies as based on rain, small-scale or large-scale irrigation agriculture, the latter associated with the first major Eastern civilizations. Adams, "The origin of cities" (1960), p. 157, suggests that border disputes between neighbouring communities dependent on irrigation agriculture drew people together in offensive or defensive concentrations. See also his *The Evolution of Urban Society* ... (1965). Mumford, *The City in History* ... (1961), pp. 29-39, presents the concept of an "urban implosion", a gathering in a limited area of many heretofore scattered and unorganized functions.

<sup>48</sup> Braidwood, "The agricultural revolution" (1960), p. 148.

<sup>49</sup> Dales, "The decline of the Harappans" (1966), pp. 92-100. See also Woolley, "The beginnings of civilization" (1965), pp. 395-397, 451-458.

<sup>50</sup> Adams, "The origin of cities" (1960), pp. 160, 166.

<sup>51</sup> Kramer, *The Sumerians, Their History, Culture and Character* (1963), pp. 88-89.

<sup>52</sup> Woolley, "The beginnings of civilization" (1965), p. 428. This author considers the possibility of a population of 360,000 for Ur about 1700 B.C. D'iakonov, *Obshchestvennyi i gosudarstvennyi stroi* ... (1959), estimates 100,000 inhabitants for ancient Lagash.

<sup>53</sup> Davis, "The origin and growth of urbanization ..." (1955), p. 431.

<sup>54</sup> Mumford, *The City in History* ... (1961), p. 62.

<sup>55</sup> Davis, "The origin and growth of urbanization ..." (1955), p. 431.

<sup>56</sup> A requirement of fifty to ninety farmers to support one man in a city has been suggested, *ibid.*, p. 432. According to Thompson, "The spiral of population" (1956), pp. 970-986, every change in man's techniques of production and in social organization affecting his ability ... to use his labour effectively, "favoured an increase in his numbers as long as he accepted a subsistence, or near-subsistence, level of living as his inevitable lot", pp. 970-971.

<sup>57</sup> Lattimore, *Studies in Frontier History* ... (1962), pp. 24-26, 141-154, 256-258, 484-488, 495-496, 503-506.

23. Thus, prehistoric and early historic developments resulted in the emergence of what could be viewed as four major types of economic regions in the world with their related demographic features:

(a) Associated city-centred, agrarian and commercial civilizations occupying the Mediterranean basin, extensive areas in Eastern Asia, and an independent zone of similar character in Middle America;

(b) Adjacent regions of village economy, extending into more isolated regions and including woodlands, of Northern Europe and Asia and to a lesser degree in the western hemisphere;

(c) Nomadic and semi-nomadic areas in inner Asia, bordering steppe lands and, to the south, the Sahara-Arabic belt;

(d) Hunting, gathering and fishing economies of tribal societies in Africa south of the Sahara, Oceania and most of North and South America.

### B. Population of the ancient world

24. Large parts of the world's population were subject to some forms of partial census enumeration near the beginning of the Christian era, but the information gleaned from such censuses is of limited value. For most regions, of course, this kind of information is lacking. Modern investigators must, therefore, rely on summary figures and estimates in ancient manuscripts; on inferences from archaeological evidence; on records of such things as grain imports, taxes, and military forces; or on some combination of such sources in the context of other historical information.

25. More plentiful sources of information and close studies made of them permit clearer discernment of trends for Europe and the Mediterranean region at this time. Indications are that by this period a decline in the free population of Greece was already established. In some of the Greek states after the age of Pericles this was probably due initially to war losses, epidemics, and migration to other regions. Later decline must be interpreted as resulting from the avoidance of marriage, avoidance of child-bearing within marriage, and exposure of infants.<sup>58</sup> A similar tendency, perhaps less extreme in degree, characterized later Roman society. The prevalence of slavery should also be noted as an inhibiting factor to population increase. Segregation of the sexes and high mortality prevented procreation among this appreciable class of society.

26. Roman censuses, taken for administrative purposes, were most frequently concerned only with citizens. Sometimes only adult males were included; in other

SOURCE: Beloch, *Die Bevölkerung der griechisch-...* (1886), p. 507.

circumstances, all household members except children.<sup>59</sup> In 1866, Beloch presented estimates of the area and population of the Empire which show a total of 54 million persons at the death of Augustus in A.D. 14, as given in table II.2. Estimates of later students range from 50 to 70 million, with upward revision of Beloch's estimate generally favoured.<sup>60</sup> More recently, the hypothesis of 100 to 110 million has been seriously considered.<sup>61</sup> Walek-Czernecki concluded that the population of Egypt must have been around 8 million in the Ptolemaic era and perhaps as high as 9 million in the first century A.D.<sup>62</sup> French historians have since concluded that Beloch's estimates for the area which is now France were too low.<sup>63</sup> Cavaignac, adjusting the records used by Beloch for an assumed omission of children, estimated 80 million persons in the Empire at the time of Augustus. He further estimated an increase to 150 million by A.D. 180.<sup>64</sup> Although Cavaignac's conclusions have not been generally accepted by other competent students, it is widely agreed that the total population of the Empire increased during the first two centuries after Augustus.<sup>65</sup>

<sup>63</sup> Landry, *Traité de démographie* (1949), p. 53. Nougier suggests 8.5 million for France in the second century A.D.; see his "Essai sur le peuplement ..." (1954), p. 262.

<sup>64</sup> Cavaignac, "Notes de démographie antique" (1935), pp. 8-9.

<sup>65</sup> Under Augustus, according to Nilsson, *Imperial Rome* (1962), p. 330, every noble Roman aged 25 to 60 was required by law to be married or betrothed; married men were given preference for state office, and the parents of three or more children received special distinction.

<sup>58</sup> Bérard, "Problèmes démographiques dans l'histoire ..." (1947); Landry, *Traité de démographie* (1949), pp. 44-47. The historian Polybius observed, "... the whole of Greece has been subject to a low birth-rate and a general decrease of the population" and attributed this condition to men's having "fallen into such a state of pretentiousness, avarice and indolence that they did not wish to marry, or, if they married, to rear the children born to them, or, at most as a rule, but one or two of them ...". Polybius, *Histories* (c. 140 B.C.; 1927 ed.) vol. 6, bk. 36, p. 385. Wolfe, however, doubted that this statement, even if true of the "urban bourgeoisie", was true of the behaviour of the "miserable country folk". See his "The economics of ..." (1932), p. 36.

27. There are references to censuses in Chinese histories for several centuries before the Christian era, but the totals given are subject to wide and inconclusive interpretation. The avoidance of enumeration was often politic, as where the consequences concerned taxation or military service. Statistics dating from A.D. 2 have been profitably analysed in spite of their many deficiencies, such as the exclusion of non-Chinese, nobles, slaves, and inmates of monasteries and the tendency to overlook women and girls. For this year, an estimate based on the number of households arrived at a population of 71 million for a China corresponding roughly to the present boundaries.<sup>66</sup> No allowance was made for omission of households or of the non-Chinese population, and a higher total is entirely plausible.

28. No extensive census enumerations appear to have been made in ancient India. For Asoka's Empire at the beginning of the third century B.C., figures of 200 to 400 million have been advanced.<sup>67</sup> It seems impossible to place much reliance on any specific estimate of total population in India at this early date, but it is known that large portions of the Indian subcontinent were already well developed.

29. For other parts of the world, no conjectures based on contemporary records seem possible. This deficiency is most serious in West and South-East Asia, where civilization was well advanced. In Northern Europe, sub-Saharan Africa, Northern Asia, Japan, the Americas and Oceania the evidence points to relatively sparse habitation in neolithic and bronze age conditions for some parts, but society in much of the regions was at the pre-agricultural stage.

30. On the basis of these estimates and considerations, it may be proposed that the world population was probably between 200 and 400 million at the beginning of the Christian era.

### C. Population trends: ancient to modern times

31. In the first millennium of the Christian era there was no sustained increase in the population of the old centres of civilization, but wide fluctuations, with occasionally very heavy losses. The population of the Roman Empire may have remained fairly constant until near the end of the fourth century, with divergent trends in different parts of the Empire. There was a slow increase of the dense population in the centres of ancient civilization (Asia Minor, Egypt and Syria) but likely a decrease in the western provinces racked by economic and political crises and barbarian invasion.<sup>68</sup> A repetition of tribal migrations and vast movements of nomadic populations again had a powerful impact on Eurasian demographic history.

32. The fifth century saw the collapse of the Western Roman Empire when it was completely overrun by Germanic tribes. It was in this century also that the Huns swept into Europe as far as France, a few centuries after their incursions into China and India. The Arabs began

their expansion in Asia, Africa and parts of Southern Europe with the rise of Islam in the seventh century, and in the thirteenth century, the pressures of the Mongol Empire, extending from China to Russia, were felt as far west as Poland and Hungary. There were also invasions into Europe by the Magyars in the ninth century and aggressive expansion by the Vikings. These continual shifts of population reflected widespread hardship and political instability. Among the numerous principalities of India, "... a king was normally at enmity with his immediate neighbours ...",<sup>69</sup> while for the peasant, the great enemy was drought. The introduction of Moslem rule by Turks brought not only religious strife, but added to the convulsions of rising and falling dynasties. The evidence of setbacks in China's growth have likewise been attributed in large measure to the disruption attendant upon dynastic successions.

33. Following the decline of Roman authority in the west, the destruction and depopulation caused by barbarian invasions were most intense in certain frontier regions, notably in Dacia (the lower Danubian region). In contrast, to a large extent barbarians were absorbed into the more firmly established populations of Italy, Spain, and Narbonese Gaul (part of southern France), without severe disruption of economic processes, according to one view.<sup>70</sup> Interpretations of economic history indicate to others, however, severe depression; communication and commercial channels were disrupted, the fields deserted and cities contracted.<sup>71</sup> These conditions were seen as arising not so much out of political disintegration, but rather from an aggravation of weaknesses inherent in the economic base of the former empire: lack of technical advance, relative low population density in the hinterlands of the small cities, and a consumer segment composed of the very wealthy living on the produce of their own estates and the very poor barely subsisting.<sup>72</sup> The institution of slavery, a deterrent to economic as well as population growth, persisted during the greater part of this millennium and even longer in the Mediterranean zone of Moslem expansion. Military captives augmented the slave population, and the slave traffic included the sale of children. Serfdom also contributed a restraining effect on demographic growth, with its limitations on the peasants' freedom to move, to marry and to control the disposition of their children.<sup>73</sup> To these adverse economic and social factors and the added devastation in the Mediterranean basin of the plagues of the sixth century were attributed the principal cause of the demographic decline.

34. After the turn of the millennium, an economic and demographic upsurge was in evidence in most of Europe. Between the eleventh and thirteenth centuries, numerous new communities emerged in Western and Eastern Europe. Signs of urban revival were already

evident in Italy by the eighth century, and by the twelfth and thirteenth centuries the cities, particularly in the north, had begun to expand beyond their old Roman walls.

35. The population of Italy fluctuated within a narrow range, and by the thirteenth century was slightly above 8 million, according to one author,<sup>74</sup> indicating a recovery to near Imperial Roman levels. With continuing fluctuations and slow increase, it has been considered probable that a level of about 11 million was reached by 1560, where it likely remained until the beginning of the eighteenth century.<sup>75</sup> Conditions in Spain during the Middle Ages, such as frequent changes of territory, the invasion and settlement by the Moors, and almost continual warfare, make it difficult to come to a conclusion about the size of the population during that period. Ten million has been estimated at the end of the fifteenth century and, after a drastic decline, somewhat over ten million at the end of the eighteenth century.<sup>76</sup>

36. Farther north, fragmentary evidence suggests that recovery and growth were faster. Levasseur raised Beloch's estimate of 5.7 million for the population of Roman Gaul to about 8 million and assumed a similar figure for the time of Charlemagne.<sup>77</sup> An analysis of a hearth count in the year 1328 provides a benchmark for French demographic history from which one author concluded that the population in the territory corresponding to Roman Gaul was then considerably over 20 million.<sup>78</sup> This estimate has been found implausibly high by many French scholars, one reason being that the resulting population density of 40 per square kilometre could not have been supported by the French economy at that time.<sup>79</sup> Nevertheless, substantial growth since Roman days was certain. The population was thereafter greatly decreased by one third to one half because of famine, the Black Death and the Hundred Years War in the course of the fourteenth and fifteenth centuries. Gains in the sixteenth century were checked by the religious wars (1565-1580).

37. Archaeological evidence for the population in Britain of Roman times has led to estimates of between 0.5 million and 1.5 million inhabitants.<sup>80</sup> The great survey of 1860, recorded in the Domesday Book, is the first substantial basis for estimates. A total of about 1,100,000, approximately equivalent to the "medium" estimates for Roman times, is indicated.<sup>81</sup> Monastic records and other local evidence point to a threefold or

fourfold increase in the next 250 years. Subsidy Rolls of 1377 originating in the poll tax levied to finance participation in the Hundred Years War provide another benchmark and, after consideration of the evidence of plague mortality, a pre-plague estimate for 1348 of 3.7 million or more is obtained.<sup>82</sup> Life-table methods show a decrease of 40 per cent from 1348 to 1377, and another decline of approximately 25 per cent by the first decade of the fifteenth century which may have reduced the population to about 2,100,000. The evidence then shows a slow increase to about 3,200,000 in 1545.<sup>83</sup>

38. The most rapid increases of population in Europe during the mediaeval period took place north of the Alps and west of the Carpathians, where the enlargement of forest clearings and the extension of agriculture provided an economic basis for the support of additional people.<sup>84</sup> An increase has been assumed for Germany from 2 or 3 million in Caesar's time to some 12 million at the beginning of the fourteenth century.<sup>85</sup> The general expansion of the sixteenth century was notable in this region after set-backs from plague in the preceding century. Likewise, in the seventeenth century the general stagnation in much of Europe was pronounced in the German states, which suffered severe losses from the Thirty Years War (1618-1648), possibly as many as 40 per cent of the inhabitants.<sup>86</sup> For the present area of Czechoslovakia, an estimate of about 0.5 million inhabitants has been given for the fifth century. Around the middle of the seventeenth century, after drastic reductions resulting from the Thirty Years War and emigration, its population may have been close to 3 million. A population of 6.3 million has been estimated for 1787.<sup>87</sup>

39. The eastern branch of the Slavic nations in East-central Europe grew and extended their area of habitation into the Russian plain.<sup>88</sup> Uralis estimated the population of Russia, after the occupation of the forest zone by Slavs, as 8.6 million persons at about A.D. 1000.<sup>89</sup> Estimates based on the census by Peter the Great in 1724 indicate a population of about 18 million within his realm.<sup>90</sup> The steppe zone, south and east of this area, was still occupied by nomadic tribes.

40. The population of the Near East fluctuated around a fairly constant level during most of the mediaeval period, but there were sharp localized reverses resulting from the destruction or out-movement of population, notably in Mesopotamia, Persia, and Turkestan.<sup>91</sup> The great irrigation system east of Baghdad ceased to function by the end of the twelfth century and depopulation

followed. In the fourth century, the eastern region of the Roman Empire is believed to have had a larger population than its counterpart in the west, increasing to about 30 million by the middle of the sixth century.<sup>92</sup> A factual basis for estimating the population of the Byzantine Empire is almost non-existent, but it seems indisputable that demographic decline accompanied the economic reverses, pestilence and wars of its last centuries. However, under early Ottoman rule there was at least vigorous urban growth; Istanbul is thought to have grown from 100,000 to 700,000 in the century between 1478 and 1580.<sup>93</sup> There is no adequate basis for assuming a distinct trend for the area as a whole, but for the end of the sixteenth century a total of 16 million has been proposed for the European and Asian parts.<sup>94</sup>

41. There has been agreement that India's population was probably about the same at the beginning of the modern period as it had been two thousand years earlier. After periods of some increase, calamities of one form or another wiped out a large part of the population, leaving the long-run trend more or less stationary<sup>95</sup> (see table II.3).

42. Advanced and likely populous civilizations were formed and destroyed in other parts of Asia, in Cambodia, for example, and in Ceylon, which has been described as a demographic prototype of South Asia. Architectural ruins and interpretation of the ancient writings suggest a sizable population supported by irrigation agriculture; a possible maximum between 7 million and 8 million has been hazarded from calculations of probable rice-paddy production in early times.<sup>96</sup> Apparently, high fertility offset high mortality and population and resources maintained a favourable balance over many centuries, with irrigation agriculture reaching its highest development in the twelfth century.<sup>97</sup> Thereafter, neglect of the irrigation works, possibly as a result of foreign invasion and internal strife, undermined the economic foundation of the civilization. Numbers were greatly reduced by malaria and other diseases, as well as by famine. No official basis for an estimate prior to 1789 is available, for which date a total of 1.8 million has been given.<sup>98</sup>

43. Only for China is there a more or less continuous record which shows fluctuations that Chinese tradition and modern scholarship alike have interpreted as related to dynastic growth and decay. According to Chen's interpretation, the beginning of a new dynasty was ordinarily followed by a period of peace and order, of cultural development and population growth. As time went on, the increasing density of population exceeded

TABLE II.3. ESTIMATED POPULATION IN SELECTED ASIAN COUNTRIES: ANCIENT TO EARLY MODERN PERIOD

<i>Dynasty and selected years</i>	<i>Year or period</i>	<i>Population (millions)</i>	<i>Year or period</i>	<i>Population (millions)</i>

<sup>a</sup> Durand, "The population statistics . . ." (1960), p. 249. Ping-ti Ho estimates about 65 million for late fourteenth century, 130 million c. 1500 and 150 million c. 1600; Ho, *Studies on the Population* . . . (1959), p. 264.

<sup>b</sup> Nath, *A Study in the Economic Condition* . . . (1929), p. 117.

<sup>c</sup> Datta, "A re-examination of Moreland's estimate . . ." (1960), p. 182. Moreland, *India at the Death of Akbar* . . . (1920), pp. 9-22, arrived at an estimate of 100 million; Davis suggests 125 million, *The Population of India* . . . (1951), p. 24.

<sup>d</sup> Durand, "The modern expansion . . ." (1967), p. 138.

<sup>e</sup> Ishii, *Population Pressure* . . . (1937), pp. 3-7.

the development of improved farming techniques and gradually the struggle for existence was intensified. Then came a period of famine and pestilence with a consequent reduction in population.<sup>99</sup> Lattimore, in interpreting the sequence of population change, emphasized the importance of migratory invasions by nomads from inner Asia into Chinese agricultural societies at times of internal confusion.<sup>100</sup> A summary of estimates is given in table II.3. In broad outline, the course of Chinese population is seen as coinciding roughly with contractions and expansions assumed to have occurred in Europe, especially after the first millennium, with a tendency for Chinese populations to be some fifty per cent larger.

44. In Japan, agriculture seems to have been practised for more than two thousand years preceding the modern period, but neolithic conditions persisted in the north of the country until the end of the first millennium A.D. On the basis of records of land distribution, Japanese scholars have prepared the estimates given in table II.3, which show a substantial growth in the Middle Ages. By the end of the seventeenth century, population may have grown to 25 million.<sup>101</sup>

45. On the basis of urban data, the population of Egypt has been put as low as 2.7 million at the time of the Arab conquest,<sup>102</sup> and under Turkish rule some centuries later it again suffered a drastic decline.<sup>103</sup> An estimate

of 2.5 million has been given for the end of the eighteenth century and only in the course of the nineteenth century did it attain levels comparable to those of the Ptolemaic Empire.<sup>104</sup>

46. For sub-Saharan Africa, demographic evidence is absent and even circumstantial historical information has been assembled only recently. The formation of the Sudanic states before the end of the first millennium and the emergence of extensive flows of trade constitute presumptive evidence of at least local increases.<sup>105</sup> Between the thirteenth and fifteenth centuries, signs of settlement and prosperity multiplied in East Africa, and to the west the Guinean states emerged. Exploration by Portuguese navigators in the first half of the fifteenth century opened about 4,000 miles of African coast, from the Senegal River to Angola, where trading centres for the overseas slave traffic were established. The first exports went to Europe in small numbers and then, after the discovery of the Americas, across the Atlantic in increasing volume.<sup>106</sup> The slave trade did not reach significant proportions until the seventeenth century, when of the untold numbers captured, almost three million Africans are thought to have survived the rigours of captivity and transport to be landed in the Americas. This traffic in itself need not have resulted in depopulation in West Africa, but with the added effects of social and political disorganization, especially in later periods, such may have been the consequence. Losses in more sparsely populated East Africa would seem to have been disastrous.<sup>107</sup> In the longer run, however, it is believed that large migrations into Eastern and Southern Africa ultimately produced substantial settlement there. The overseas shipment of human cargo lasted for more than four centuries (1442-1880), for "... local African custom, the profits of the trader, the needs of the planter, and the barrenness of Negro women under slave conditions, all combined to impose the need for continued importation of Negroes to supply a labour market always being depleted".<sup>108</sup> Although no pretension to accuracy can ever be made, a conjecture of the number captured has been as high as 20 million. It has been further estimated that perhaps only one third of those captured survived to be placed on sale in the New World.<sup>109</sup>

<sup>104</sup> Issawi, "Population and wealth ..." (1956), pp. 690-691.

<sup>105</sup> Ibn Battuta, visiting the Mali Empire in the fourteenth century, noted its agricultural and commercial prosperity, and the ease and safety of travel. See Oliver and Fage, *A Short History of Africa* (1962), p. 89.

<sup>106</sup> Tannenbaum, *Slave and Citizen* ... (1947), pp. 14-16. The European slavers' activities were confined to the ports; their supply from the interior was totally controlled by the Blacks for three centuries. Slavery in Africa was part of the cultural scene, but its conditions were not to be compared to the harshness of those which existed in the Americas; see Elkins, *Slavery* ... (1963), pp. 95, 96.

<sup>107</sup> Oliver and Fage, *A Short History of Africa* (1962), pp. 120-122.

<sup>108</sup> Tannenbaum, *Slave and Citizen* ... (1947), pp. 14, 36. On the average, an African slave was expected to survive about eight years on a Brazilian plantation; Furtado, *The Economic Growth of Brazil* ... (1963), p. 46.

<sup>109</sup> Tannenbaum, *Slave and Citizen* ... (1947), p. 29. The author briefly refers to early records of numbers of African slaves in Europe and the Americas at different dates, and the extent and implications of this traffic as a commercial venture; see pp. 5-20, 30-38.

47. In the Americas, European conquest led to native depopulation, particularly drastic in what is now Latin America. The indigenous population had remained sparse in most of North America, but in Middle and South America and in Mexico the practice of sedentary maize agriculture and the urban, metal-using cultures of the Aztecs, the Incas and the Chibcha had favoured population growth for some centuries and supported sizable agglomerations. The population of the Caribbean, numbering hundreds of thousands in the pre-Hispanic period, disappeared within a few decades following the Spanish conquest. For central Mexico, comprising about 25 per cent of the present-day area of the country, a decline from around 25 million in 1519 to slightly over 1 million near the end of the century has been suggested, with a recovery to about 3.7 million by 1793.<sup>110</sup> Rosenblat arrives at approximately 3 million for this date, and in general takes issue with the methods of Borah and Cook in obtaining estimates.<sup>111</sup> In South America, especially in the Andean regions, infectious diseases of European origin are believed to have spread even in advance of the Conquest and within a short time after that event to have reduced a population of many millions to a much smaller size. Willcox's estimate of 12 million for Latin America in 1650 (with which Carr-Saunders agreed, but which Willcox later revised to 7 million) may represent a mere fraction of a previously much larger population.<sup>112</sup> The figure of one million for North America at that date is generally accepted.

48. In summary, it appears that following the stagnation of the Dark Ages, there were beginnings of expansion of population in the period A.D. 1000-1650. Growth in Europe shifted from the Mediterranean area of antiquity to the north-west and notably to the central and eastern regions of active colonization. Growth was probably substantial in China, greater in the south than in the north as heretofore, and in Japan. India seems to have remained unchanged, as did Africa where it is believed that there were gains in the east and south balanced by losses in the west. Western Asia experienced decline, and a burgeoning indigenous American population was cut back drastically by disease and despair following European conquest.

<sup>110</sup> Borah and Cook, *The Aboriginal Population* ... (1963), pp. 4, 88; tribute records were studied as the source of these estimates. The figure of 25.2 million is based upon a family size of 4.5. A possible family-size factor of 3.5 would give a total population of 20 million; one of 5.0, 28 million. From various interpretations of other aspects of the material, the range would be 18.8 million to 26.3 million. The authors calculated the population to be about 6.3 million in 1548. See also their *The Population of Central Mexico in 1548* ... (1960) and Cook and Simpson, *The Population of Central Mexico* ... (1948), p. 38.

<sup>111</sup> Rosenblat, *La población de América en 1492* ... (1967), p. 26.

<sup>112</sup> Willcox, "Increase in the population ..." (1931), p. 62; and his *Studies in American Demography* (1940), pp. 37-38. Carr-Saunders, *World Population* ... (1936), p. 30. The population of pre-conquest Latin America remains a subject of much controversy. Rosenblat proposes about 12.5 million for 1492: *La población indígena* ... (1954), vol. 1, p. 102. Chaunu, "La population de l'Amérique indienne ..." (1964), p. 117, on the basis of estimates for central Mexico in Borah and Cook, *The Aboriginal Population* ... (1963), would at least double the figure of 40 million which was rejected by Rivet as too high; see Rivet, *Les origines de l'homme américain* (1957).

49. Such declines in mortality as occurred were not sustained for a significant length of time; increased density brought about by more prosperous conditions carried with it greater vulnerability to epidemic disease. The most severe scourges were the Plague of Justinian and the Black Death. The first apparently spread from a source in the hinterland of South-West Asia throughout the world, from A.D. 542 to the end of the century. Estimates have been given that half the Byzantine Empire was destroyed by A.D. 565, and that the total cost to the world was 100 million persons. The Black Death reached Europe in 1346, probably from Central Asia, and has been described as the most frightful pandemic ever to afflict mankind.<sup>113</sup> Even before the appearance of this scourge, however, an upsurge in European population growth had slowed.<sup>114</sup>

50. During these centuries, periods of famine, pestilence and war alternated with recovery in most areas, with consequent slow net population increase for some. In the century following the Plague, recovery seems to have been most rapid in Italy,<sup>115</sup> but for many regions there is evidence of great contraction, abandonment of homesteads and villages and of labour shortage.<sup>116</sup> There was resumption of demographic growth by A.D. 1500 and, in general, the sixteenth century was one of expansion, notably in the German frontier regions. Although fertility was generally high, it cannot be assumed that it was at a maximal "natural" level. As discussed in chapter IV, the postponement of marriage reduced fertility considerably below its highest potential in Europe; in all parts of the world sexual taboos, extended periods of lactation and abortion are assumed in different measure to have restrained reproduction, and resort to infanticide and abandonment of infants was a further deterrent to population growth.

51. The relationship between population growth and economic development was complex. Population increases seem to have induced migration and conquest but colonization also provided the opportunity to multiply, and the sustained movements in population seem to have been responses to conditions that favoured peaceful extension of cultivation and commerce. The uniformities sometimes observed in the movements of population in different regions raise the question whether climatic change, affecting harvests, and autonomous variations in the intensity of epidemic diseases were factors which decisively affected demographic growth.<sup>117</sup>

52. The estimates of world population at the middle of the seventeenth century, referred to in section E below, remain indications of the order of probable magnitude rather than measurements. They cannot be used to test propositions about the dynamics of population growth, but the impression that world population in 1650 had

not yet doubled its size in the early years of the Christian era is compatible with the view that the rate of expansion was lower in this period than in the preceding several thousand years.

#### D. Population growth in the modern period

53. Early in the modern period in Europe, the nation-state as a political entity had evolved, with an administrative machinery adaptable to a vast expansion of commerce and the exploitation of overseas settlement. The new mercantilist policy included in its body of theory expressions by some writers on the benefits of a numerous population (see chapter III, section B). Recognition of the utility of statistical data for many activities of government fostered speculation as to the number of a country's inhabitants. Prompted by the vagaries of current speculation, John Graunt attempted a more careful estimate of the population of England and Wales, published in 1662.<sup>118</sup> Various suppositions concerning size of populations were examined by Riccioli, who produced in 1661 what was perhaps the first considered attempt to estimate the population of the world.<sup>119</sup> Later, partial enumerations and estimates for limited areas were undertaken, and even a few counts of whole populations attempted. An instance of the latter was the series of house-to-house counts of all inhabitants in the colony of New France, that taken in 1665 probably being the first total census ever accomplished. The first total national population census in continental Europe was completed in Sweden in 1749, but it was not until 1801 that France and England overcame resistance to a similar undertaking. The newly established United States of America included a provision in its Constitution for decennial censuses and promptly conducted the first in 1790.<sup>120</sup>

54. Such early endeavours and subsequent progress in more precise population accounting, including registration of vital statistics, were principally confined to areas of European settlement. In China, systems of registration designed to serve various purposes over the centuries have been subject to a number of interpretations as sources of population totals.<sup>121</sup> Early Japanese counts were not preserved and the practice was gradually abandoned. A resumption of national census-taking in the eighteenth century was not representative of the total

<sup>113</sup> See Hirst, *The Conquest of Plague* ... (1953), pp. 10-16.

<sup>114</sup> Helleiner, "Europas Bevölkerung und Wirtschaft ..." (1954), pp. 254-269.

<sup>115</sup> Cipolla *et al.*, "Rapport collectif" (1950), pp. 69-71.

<sup>116</sup> Abel, *Die Wüstungen des* ... (1955).

<sup>117</sup> See, for example, Utterström, "Climatic fluctuations and population ..." (1955); see also Le Roy Ladurie, "Climat et récoltes ..." (1960), pp. 458-465, and his "Histoire et climat" (1959).

<sup>118</sup> The work of Graunt and his followers, who introduced quantitative research methods, named "political arithmetic", in estimating population numbers, is discussed in chapter III, section B.

<sup>119</sup> See Willcox, "Increase in the population ..." (1931), vol. 2, pp. 44-49, for a brief evaluation of this and other contemporary estimates for the world.

<sup>120</sup> For a brief account of early censuses, see Wolfe, "Population censuses before 1790" (1932).

<sup>121</sup> An examination of official population records beginning 1368 is discussed in Ho, *Studies on the Population* ... (1959), pp. 3-100. Perhaps the most comprehensive record, the *Pao-chia* of the Ch'ing dynasty (1644-1912), is described in detail by Hsiao, "Rural control in nineteenth century China" (1953).

TABLE II.4. VARIOUS ESTIMATES OF POPULATION OF THE WORLD AND MAJOR REGIONS, 1750-1965

SOURCES: Carr-Saunders, *World Population* ... (1936), p. 42. Willcox, *Studies in American Demography* (1940), p. 45; estimates for America have been divided between northern America and Latin America by means of detailed figures presented on pp. 37-44. Durand, "The modern expansion ..." (1967), p. 137. Estimates for 1950 and 1965 from United Nations, *World Population Prospects as assessed in 1968* ...

Note: Because of rounding, the sum of the parts does not exactly equal the total shown in all cases.

<sup>a</sup> Estimates for Asia and Europe in Carr-Saunders' and Willcox's series have been adjusted to include the population of the Asiatic USSR with that of Europe rather than Asia. For this purpose, the following approximate estimates of the population of the Asiatic USSR were used: 1750, 4 million; 1800, 5 million; 1850, 8 million; 1900, 22 million. Durand's estimates for USSR only are shown.

<sup>b</sup> Latin America is distinguished from northern America at the southern border of the United States and comprises Middle America, South America and the Caribbean Islands.

<sup>c</sup> United States, Canada, St. Pierre and Miquelon.

<sup>d</sup> Range exists in USSR component only, shown separately below.

population, but in 1872 effective registration was instituted by the Meiji régime. Reliable censuses date from 1920.<sup>122</sup>

55. To the present time there are large regions of the world where development of demographic statistics has scarcely begun. Demographic historians are uncovering and interpreting an increasing amount of information that gives new insights into population movements throughout the modern period. Nevertheless there remain large gaps that can never be filled, but only bridged by improved conjectures. The estimates prepared by Willcox and by Carr-Saunders for the world and its major regions for the period 1650 to 1900 have received wide acceptance from the time of their first publication in the 1930s,<sup>123</sup> but a reassessment of growth trends has now become profitable. Results of the most recently published study to date<sup>124</sup> are presented with the Willcox and Carr-Saunders estimates in table II.4 for fifty-year intervals from 1750 to 1900.

56. Working back to 1650, Willcox arrived at 470 million and Carr-Saunders 545 million for the total population of the world, and deductions of both authors for the century following imply a net growth rate of three per thousand.

57. A quickening of this modest rate was apparent for the period 1750-1900. Medium estimates for the latest series given in table II.4 furnish a convenient reference point as centres of ranges of low and high variants "... not intended to define absolute limits, but to indicate the width of estimated ranges of relative plausibility without excluding the possibility that the true numbers might have been outside these ranges".<sup>125</sup> It may be observed that estimates in the two earlier series fall within the ranges outlined in the later series in nearly all cases, and when outside it is to a negligible degree. These recent estimates show upward revisions for all regions except Africa in 1900 and Oceania.

58. The magnitude of Asia's population, roughly about two thirds of the world total until 1850, after which it was closer to half, make the disparity in estimates for that region more significant. The principal reason for the variations in Asia is the different evaluations of the conflicting evidence with respect to the population of China. Totals for this country, as a component of the medium estimates for Asia given in table II.4, comprised approximately one quarter of the world total in 1750 and 1900 and one third in 1800 and 1850.<sup>126</sup> Willcox, after examining various Chinese sources and making certain allowances, reached totals for 1650 and 1900

between which he interpolated his series, assuming a constant rate of growth during 1650-1850.<sup>127</sup> Carr-Saunders accepted higher estimates for 1650 and 1900 and then pursued the same method.<sup>128</sup> Durand's estimates for China's population prior to 1900 were based on official sources rejected by both Willcox and Carr-Saunders, while for 1900 he had the 1953 census total on which to base a backward projection at an assumed rate of growth.<sup>129</sup>

59. For Africa, Carr-Saunders made an allowance in his 1850 and earlier estimates for the presumed depopulating effect of the slave trade, while Willcox apparently considered the continental total too uncertain to warrant any change in the estimates until 1900, when he accepted a figure which represented substantial growth. For Africa south of the Sahara, where a foundation for calculations is almost totally lacking, Durand's hypothesis concurred in this pattern of growth, but at a lower level. Wider acquaintance with North Africa recommended its separate treatment; totals for 1750-1900 were obtained by backward extrapolation from a United Nations estimate for 1920.<sup>130</sup>

60. The population enumerations and registration of births and deaths carried out in many parts of Latin America from the colonial period onward had many deficiencies, and recent studies as well as improved population statistics have indicated that too great dependence on these records have produced estimates believed to be considerably understated.<sup>131</sup> Thus, the low variant of the most recent series given in table II.4 somewhat exceeds the estimates of the two earlier series.

61. The closer accord of population estimates for the remaining areas of European settlement is a reflection of the progressive reliability of their statistical data during the period here considered. Carr-Saunders accepted the results of Willcox's thorough examination of the work of scholars concerned with the number of inhabitants of modern Europe.<sup>132</sup> Subsequent advances in this field of investigation have led to estimates which consistently equate the earlier estimates with the low variant shown in table II.4. Upward revision was deemed appropriate for the USSR, as well. When Europe excluding the USSR is considered, the range of plausible estimates narrows appreciably in 1800 and is non-existent thereafter.

62. Emigration from Europe to the New World, beginning modestly in the sixteenth century and swelling

<sup>122</sup> An Imperial decree in A.D. 645, ordering that a census be taken every six years, was followed for about 150 years. Censuses taken in the Tokugawa period excluded large segments of the population and required substantial adjustment for later students to reach approximations of the country's total. Ishii, *Population Pressure* ... (1937), pp. 2, 5-8, 48-56.

<sup>123</sup> Willcox, *Studies in American Demography* (1940), pp. 22-51; these are revisions of previous estimates, published in his "Increase in the population ..." (1931), pp. 33-82; Carr-Saunders, *World Population* ... (1936), p. 42 (for 1650-1933).

<sup>124</sup> Durand, "The modern expansion ..." (1967), pp. 137-138.

<sup>125</sup> *Ibid.*, p. 136.

<sup>126</sup> Medium estimates for China at fifty-year intervals 1750-1950 are (in millions): 200, 323, 430, 436 and 560, *ibid.*, p. 137.

<sup>127</sup> Willcox, *Studies in American Demography* (1940), pp. 35, 48, 532; a thorough discussion of the author's approach to estimating the population of China is given in appendix II, pp. 511-540. It is now apparent that the total for 1650 was based on a misapprehension of the source of the data. Willcox believed it to relate to a count of households when in fact it was concerned with a customary tax assessment which had grown out of an imposition of compulsory labour service on most adult males at an earlier period. See Ho, *Studies on the Population* ... (1959), pp. 24-35.

<sup>129</sup> Durand, "The modern expansion ..." (1967), pp. 147-148.

<sup>130</sup> *Ibid.*, pp. 152-153.

<sup>131</sup> *Ibid.*, p. 156. The author cites, in particular, Castro, "El desarrollo de la población ..." (1959), pp. 425-443.

<sup>132</sup> Willcox, *Studies in American Demography* (1940), pp. 22-51, includes comprehensive references to sources.

to large proportions at the beginning of the twentieth century, profoundly altered the map of world population distribution. In spite of the magnitude of the exodus, however, Europe excluding the USSR steadily maintained around 16 per cent of the world's total population as estimated at fifty-year intervals from 1750 to 1950. The principal areas in which the European emigrants settled, the Americas, the Asian part of the Russian Empire and Oceania, experienced rapid growth of population, due to the high rates of natural increase among the migrants and their descendants as well as to the immigration itself. The proportion of the world's total population in areas of European settlement increased from about 24 per cent in 1750 to 28 per cent one hundred years later and to 36 per cent in 1900 and 1950.

63. The movement of Europeans to Africa and Asia has been small relative to the total population, and has been nearly balanced by the migrations of Africans and Asians to the European cultural sphere. The importation of African slaves, it should be noted, added considerably to the population of the Americas until 1850.

64. Incidental to the transfer of populations was the cultural diffusion which modified customary patterns of living. In modern times, improved communications permit on an expanding scale the spread of some factors affecting population trends which was formerly accomplished at a much slower pace by migrations.

## 1. EUROPE

65. In addition to the scattered first attempts at census-taking in the eighteenth and early nineteenth centuries, there were some accountings of the populace for fiscal and administrative purposes covering smaller territories and in cities. These sources, reinforced by deductions from known economic and other related conditions gave the principal indication of population sizes. Ecclesiastical registers of baptisms, marriages and burials have also been a valuable source for demographic analysis, especially when associated with epidemics, crop failures, wars and other historical events.<sup>133</sup> Detailed analyses of fertility and mortality levels have been made from the reconstitution of families over several generations from local parish records by French historical demographers, and similar studies for social classes from the beginning of the sixteenth century have added to this body of knowledge.<sup>134</sup> The development of civil registration on a national scale had its inception in this period, but because of deficiencies, data from this source, for some countries until fairly

<sup>133</sup> See, for example, Mols, "Introduction à la démographie ..." (1954); Meuvret, "Les crises de subsistance ..." (1946); and Eversley, "A survey of population ..." (1957).

<sup>134</sup> See, for example, Fleury and Henry, *Des registres paroissiaux* ... (1956); Gautier and Henry, *La population de Crulai* ... (1958); and Goubert, *Beauvais et le Beauvaisis* ... (1960); Hollingsworth, "The demography of the British peerage" (1964), pp. 29-70; Peller, "Births and deaths among Europe's ..." (1965), pp. 87-100.

recently, are subject to many adjustments and interpretations.<sup>135</sup>

66. During the course of the seventeenth century, Europe had endured a series of disasters—severe cold, crop failures and famine, rebellions and wars, of which the Thirty Years War was one of the most devastating in history. Perhaps the greatest scourge was the Plague, which entirely ceased only in the early part of the eighteenth century. These afflictions did not appear simultaneously nor to the same extent in all areas. Where there was growth in some regions, it was offset by loss in others, so that conclusions as to stagnation in the trend of total European population would seem reasonable.

67. From the beginning of the eighteenth century, there was an amelioration of conditions formerly marked by calamities. As seen by some, at this point domination by nature was modified by increasing and more deliberate control of man over his circumstances, and a period of economic and demographic growth began.<sup>136</sup> Although from country to country the turning point varied, the upward demographic trend was general in most parts of Europe and was to continue at an accelerating rate into the twentieth century. Its initiation is frequently credited to lowered death rates, resulting chiefly from a lessening of peaks of mortality. The disappearance of the Plague from Western Europe, after a final brief outbreak in Provence in 1720, is widely credited with furthering this advance.<sup>137</sup> Increased colonization and expansion of arable land in Eastern and Northern Europe and the beginning of the Industrial Revolution, first in England about 1750<sup>138</sup> and next in other countries of Western Europe, were also major contributory factors. Various opinions as to the effects of the Industrial Revolution on population growth are discussed below.

68. Laslett's careful investigations of conditions in England on the eve of the Industrial Revolution led him to agree with Gregory King's estimate of average expectation of life at birth for both sexes as 32 for England at the end of the seventeenth century.<sup>139</sup> The analysis of parish records by several scholars has given an indication

<sup>135</sup> Methods for the use of early civil and parish registers as maintained in France are given by Fleury and Henry in *Nouveau manuel de dépouillement* ... (1965), superseding their earlier *Des registres paroissiaux* ... (1956). For studies of population trends in various parts of Europe based on parish registers, early censuses and other types of demographic records, see Société de démographie historique, *Annales de démographie historique*, 1965 ... (1966); —, 1966 ... (1967).

<sup>137</sup> Helleiner, "The vital revolution reconsidered" (1965), pp. 85-86. "... perhaps only a society freed from the fear as well as from the material and spiritual consequences of sudden death was able to achieve that high rate of intellectual and technical progress without which population growth could never have been sustained", p. 86.

<sup>138</sup> Although 1750 is generally accepted as marking the advance appearance of the Industrial Revolution, Ashworth states: "It would be truer to say that between 1760 and 1830 many of the essential foundations of an industrial revolution were laid in Great Britain, and that on a very limited part of them a notable structure was erected; but a very large part of the building was left for completion later." *A Short History of the International Economy* ... (1952), p. 19.

SOURCES: These data were compiled by Glass and Eversley eds., *Population in History* ... (1965), p. 21, from the following sources: Henry, *Anciennes familles genevoises* ... (1956); Hollingsworth, "The demography of the British peerage" (1964); Peller, "Births and deaths

among Europe's ..." (1965); Struyck, *Les œuvres* ... (1912); Gautier and Henry, *La population de Crulai* ... (1958); Delaporte, *Evolution de la mortalité en Europe* ... (1941).

of the progress in extending the life span in succeeding years. While these data, summarized in table II.5 relate to a favoured segment of society, they nevertheless signify a general trend.

69. Where population expanded in an agricultural economy, it is probable that accelerated growth was also due to early marriage and high fertility (as was the case in North America in similar circumstances) as well as less prominent peaks of mortality. The growth of population associated with the rise of manufacturing industry may similarly have been induced by increased economic opportunity and early marriage. This interpretation of the interaction in the process of industrialization of long-term growth in both population and output interjects a modification in the general view that lowered mortality gave the primary impetus to an upsurge in numbers. In the case of Britain, it has been conjectured that for the period beginning with the 1740s, provision for the increasing population derived from growth in output forestalled a rise in the death rate; growth in population, augmenting the labour force, permitted the pace of industrial develop-

ment to keep its momentum, and the accompanying rise in demand and prices was an incentive to expansion and innovation. Greater employment opportunities then encouraged family formation at earlier ages.<sup>140</sup>

70. The sequence of first accelerating, then declining rates of population increase in Europe is explained by the relative timing of the declines in both birth and death rates during the modern era. The sustained excess of births over deaths which had apparently become normal in Europe during the eighteenth century produced moderate population increases over fairly long periods of time in spite of short-term fluctuations in periods of economic prosperity or adversity. This excess was augmented during the nineteenth century as mortality rates dropped while birth rates generally remained high. The downward trend in the birth rate evident by the latter part of the nineteenth century was nevertheless outpaced by falling death rates. Growth was steady, from an estimated average rate of 6.2 per thousand for 1851-1860 to

<sup>140</sup> Deane, *The First Industrial Revolution* (1965), p. 34.

9.9 for 1891-1900,<sup>141</sup> and persisted in the first years of the twentieth century in spite of the swelling stream of overseas emigration.<sup>142</sup> Subsequently, death rates continued on their downward slope, but the fall in European birth rates quickened, with the result that population growth became slower.<sup>143</sup>

71. This pattern is illustrative of the demographic transition from high to low mortality and fertility, in both instances nearly in balance and permitting only slow population growth, if any. In its classic progression, the first stage produced rapid population increase as mortality declined while fertility remained high. In the second stage, the onset of fertility decline accompanied a continued lessening of mortality, but the age-structure established by the first stage was still favourable to high birth rates and a continuation of marked expansion. The transition was completed in the third stage, with birth rates nearer a low level of death rates.

72. The earliest reliable vital statistics for any region have made it possible to trace this transition in the demographic history of the Northern European countries since 1735.<sup>144</sup> During the greater part of the eighteenth century, there were wide fluctuations and great variation among areas, but the long-term trend was one of moderate growth. Trends for this and following centuries are given in table II.6 below. Fertility may have been somewhat lower than the prevailing level in Western Europe, possibly influenced by marriage patterns and some attempt at limitation. From the second half of the century, a slight lowering in the birth rate is indicated. A brief period of higher rates around the middle of the nineteenth century was followed by uninterrupted decline. Mortality rates also seemed to be relatively low at the beginning of the eighteenth century, showed some increase, and between 1750 and 1790 appeared nearly stationary, after which a marked descent continued into the next century. Overseas emigration from Scandinavia became important after the middle of the nineteenth century, but the upward movement of natural increase, begun about 1800 and continuing until the last quarter of the century, had a somewhat stabilizing effect on fluctuations in the growth rate.<sup>145</sup> Thereafter, the fall was more rapid for births than for deaths, and decline continued into the twentieth

TABLE II.6. AVERAGE ANNUAL RATE OF POPULATION GROWTH (PER THOUSAND) IN NORTHERN EUROPEAN COUNTRIES

Period	Sweden	Norway	Denmark	Finland
1735-1800 .....	5	7	3	12
1801-1900 .....	7	9	9	11
1901-1940 .....	6	7	11	9

SOURCE: Gille, "The demographic history ..." (1949), p. 38.

century. Average annual increase rates per thousand for ten-year periods beginning 1850 were 11, 7, 8, 11 and for 1901-1905, 8. For 1931-1940, these rates were: Sweden, 3; Norway, 5; Denmark, 7; Finland, 7.

73. Thus, the modern demographic transition appears to have been first set in motion in Scandinavia and Northern and Western Europe, where there was a general lowering of mortality throughout the nineteenth century, while fertility remained high until the last quarter. England's experience differed somewhat from that of the other countries in that the beginning of sustained population growth is placed at about 1750, concurrent with its modern economic growth. That the downward trend of births began in the last quarter of the nineteenth century appears indisputable, but whether rising fertility or falling mortality determined population increase in the initial stage of the transition is widely discussed.

74. Several scholars have investigated the quality of the data used to calculate birth and death rates prior to the beginning of civil registration in England in 1837.<sup>146</sup> One of these scholars found little significant change in mortality between 1700 and 1821 and terms indications of its fall after 1780 a "statistical mirage". He favours rising fertility from more and earlier marriages, beginning about 1755, as decisive in the expansion of early nineteenth century population.<sup>147</sup> The rise in birth rates from earlier marriage is seen as sustained by improved economic conditions by Habakkuk;<sup>148</sup> others doubt that the drop in age at marriage was sufficient to affect fertility trends substantially. They argue that population increase resulted mainly from reduced death rates, because of improved economic and social conditions rather than advances in therapeutic medicine.<sup>149</sup> This counters a conclusion that medical advances independent of the effect of the Industrial Revolution on the standard of living explain population growth in the mid-eighteenth century.<sup>150</sup>

75. The two most noteworthy exceptions to the general pattern were France and Ireland. The rate of population

<sup>141</sup> Habakkuk and Postan, eds., *The Cambridge Economic ...*, vol. 6 (1965), p. 62.

<sup>142</sup> For the first decades of the twentieth century, a time lag of one or two generations is noted in the decrease in births and deaths from West to East, via North and Central Europe, with the First World War having only a temporary effect. Frumkin, *Population Changes in Europe ...* (1951), p. 13.

<sup>143</sup> The statement of the sequence of events represents the consensus of a number of authors who have examined the available evidence on European population trends during the period in question. growth in France, never high in modern times, declined in the nineteenth century from an average of about 5 per thousand for the first two decades.<sup>151</sup> The rate of natural increase, at a similar level at the beginning of the century, fluctuated from mid-century in a steadily declining trend to about zero at the end of the century, followed by a brief increase and then decline for the years before the First World War.<sup>152</sup> This downward trend was attributable to the early decline in fertility which started around the time of the French Revolution, possibly earlier.<sup>153</sup> Genealogies of the French aristocracy reveal that limitation of family size in that group, presumed to have begun in the seventeenth century, led to a sharp drop in marital fertility in the eighteenth. Low net reproduction rates fell further to 1 by 1850, indicating that fertility was barely adequate for replacement. The rate remained below 1 in the last few years of the century and the first half of the twentieth.<sup>154</sup> Regional variations were pronounced, however, and fertility remained high in industrial and very remote areas. Mortality gradually and slowly reached lower levels.

76. In Ireland, the population grew at rates comparable to those of England and Wales between 1780 and the Great Famine of 1846-1847, by which time it had reached about 8 million.<sup>155</sup> The population of the Republic of Ireland in 1861 was 4.4 million; by 1925, it had fallen below 3 million, and has never recovered. The early decrease has been attributed primarily to the effect of the potato famine, which caused excess deaths and stimulated out-migration (see chapter VII, sections A and B). In addition, however, the rate of natural increase was held to a low level by delayed marriage and consequent low fertility.<sup>156</sup>

77. The period of most rapid growth apparently was reached in France and Ireland during the early part of the nineteenth century, in England in the 1870s, in Scandinavia in the 1870s and 1880s and in Germany during the 1890s and 1900s.<sup>157</sup> In Germany, from the middle of the nineteenth century rapid growth was associated with both industrialization in the west and

continuing colonization in the east. According to a study of Northern and Western Europe in the second half of the nineteenth century, net reproduction rates in Prussian agricultural areas were found to be on about the same level with those in industrial areas.<sup>158</sup> This contrasts with the situation in France, where reproduction rates in most rural sectors were rather low.

78. The cycle of rising and falling rates of population increase developed later in Southern and Eastern than it did in Northern and Western Europe, with the period of most growth postponed in various parts until the first, second or third decade of the twentieth century.<sup>159</sup> In Eastern Europe, not including the Soviet Union, the rates of population growth were higher than the general European average throughout the nineteenth century. In the first decade of the twentieth century, crude birth and death rates around 35-40 and 25, respectively, sharply distinguished the countries of this area from Western Europe.<sup>160</sup>

## 2. USSR

79. The only population census in the Russian Empire was taken in 1897, from which has been derived an officially estimated total of 125 million for the present area of the Soviet Union. Taking into account questions of accuracy and adjustments for coverage, the medium estimate of 134 million lies within a range of 127 to 140 million for 1900 (see table II.4). Estimates for the eighteenth and nineteenth centuries are based on enumeration of taxable males and are difficult to interpret for purposes of comparison.<sup>161</sup> Nevertheless, growth rates above those for Europe appear to have been maintained throughout the past 200 hundred years in spite of severe cut-backs at the time of the First World War and a net loss during the Second.

80. The eighteenth century and early years of the nineteenth were marked by a number of wars, followed by relative peace until the Crimean War in 1853-1856. Perhaps the most significant events of the latter half of the century were the abolition of serfdom, accompanying agrarian reform and gradual expansion, and the beginnings of industrial development. Crude birth rates around 50 in European Russia for 1861-1900, declining to about 43 in 1913, were obtained from registers maintained by the Orthodox Church. The death-rate decline was more rapid, from about 37 to 27; the highest rate of natural increase during the period was 17.6 for 1911.<sup>162</sup> After

<sup>151</sup> Landry, *Traité de démographie* (1949), p. 57.

drastic decline during the First World War, the birth rate gradually rose to a peak of 45 in 1927 for the USSR.<sup>163</sup> Thereupon, with greatly increased industrialization and urbanization, steady decline was established. A decline in the rate of growth, from 11 per thousand in the 1920s to 9 in the 1930s, was markedly reversed after the Second World War; a rate of 17 was registered for the 1950s.<sup>164</sup>

### 3. NORTH AMERICA

81. The spectacular growth of North American population after initial settlement by the Europeans was not due primarily to immigration. In that region of almost limitless frontiers, marriage was early and universal and marital fertility extremely high. In Canada, church registration records provide reliable data on population movements in the seventeenth and early eighteenth centuries. The inhabitants of European descent numbered 17 in 1611. By 1763, when Canada was transferred from French to British Government, the total had grown to about 65,000 from an estimated 10,000 original settlers (some of whom located in what is now the north-eastern United States).<sup>165</sup> The first of a series of decennial censuses gave a total of over 2.4 million in 1851, less than 150,000 being of non-European origin. One hundred years later, at 14 million, the population had multiplied more than fivefold. External migration has been a prominent feature of Canadian population history, with heavy in-migration countered somewhat by return-migration and by a gravitation to the United States (see chapter VII, section C). The French Canadian segment, little affected by migration since 1671, has retained its cultural homogeneity to an unusual degree. Despite the heavy volume of in-migration elsewhere, the proportion of Canada's total population in the Province of Quebec has fallen only from 37 per cent in the middle of the nineteenth century to slightly under 30 per cent during the present century.<sup>166</sup> Its increase has come from birth rates among the highest

in the world in earlier times.<sup>167</sup> With reference to the eighteenth century, Henripin has calculated a net reproduction rate of 1.93, amounting to a doubling of the population every thirty years.<sup>168</sup> In recent years, the crude birth rate has exceeded that of any of the more developed countries.<sup>169</sup>

82. The trend of population growth in the United States during the nineteenth century differed from that in Western Europe in three major respects: (a) the rate of natural increase at the beginning of the century was much higher in the United States than in Western Europe; (b) the rate of natural increase declined throughout the century (in contrast to the rising rate in most European countries) because of a steady decline of the birth rate beginning much earlier than in most areas of Europe. The estimated annual numbers of births per thousand women 15 to 44 years old in the United States during the first three decades of the nineteenth century averaged 276, 267 and 250, respectively; they dropped to 208 in 1840-1850, 146 in 1880-1890, and 100 in 1920-1930;<sup>170</sup> (c) heavy immigration prevented a corresponding drop in the rate of total population growth during the first half of the nineteenth century; the population increased between 33-36 per cent in each decade 1790-1860. From 1860 until the outbreak of the First World War, the rate of growth decreased in spite of an increasing volume of immigration. After the First World War, the birth rate and the volume of immigration continued to decrease and the average annual rate of growth declined to 0.7 per cent in the decade 1930-1940 which included years of severe economic depression.<sup>171</sup> This rate climbed further to its highest level in fifty years, 1.6 for the periods 1945-1950 and 1950-1960, ascribable largely to the high birth rate customary in post-war years and to a decided trend in child-bearing at earlier ages. Canadian rates of growth followed a similar course, although markedly higher. Under the impact of heavy immigration, the Canadian peak in the same fifty-year period was 2.8 for 1951-1956, followed by a rate of 2.5 per cent for 1956-1961.<sup>172</sup>

### 4. LATIN AMERICA

83. The beginning of the modern age registered a low point in the population history of Latin America. During the first 175 years of colonization, the hardship of European settlers and African slaves was insufficient to

<sup>163</sup> Uralnis, "Dynamics of the birth rate ..." (1967), p. 232.

<sup>166</sup> Canada, Dominion Bureau of Statistics, *Eighth Census of Canada, 1941* (1945), vol. 1, pp. 4-5. The percentage of French origin in all of Canada has remained around 30 per cent for the past 100 years. Biraben, "Le peuplement du Canada français" (1967), p. 137.

<sup>167</sup> Kuczynski, *Birth Registration and ...* (1930), pp. 199-200. According to an analysis of the Roman Catholic population of Quebec, preponderant in that Province, the crude birth rate was generally in the 50s in the eighteenth century. Thereafter, decennial averages were in the 40s until a rate of 39 was obtained for 1921-1925 (34 for 1926-1928).

<sup>168</sup> Henripin, *La population canadienne* ... (1954), p. 74.

<sup>169</sup> Crude birth rates of 30 are given for 1946-1950 and 1951-1955, and of 26 in 1961-1965. Canada, Dominion Bureau of Statistics, *Canada Year Book, 1963-64* (1964), p. 220.

<sup>170</sup> Thompson and Whelpton, *Population Trends in the United States* (1933), p. 310.

<sup>171</sup> United States, Bureau of the Census, *Statistical Abstract* ... (1946), pp. 4, 71.

<sup>172</sup> United Nations, *Demographic Yearbook, 1962* ... (1963), p. 264; ———, *1964* ... (1965), p. 158.

compensate for the drastic depletion in the sixteenth century of the indigenous population and there was general decline.<sup>173</sup> A fairly stabilized demographic situation is believed to have prevailed during most of the remainder of the colonial period. Increases thereafter produced a steadily rising trend in pronounced contrast to the more precipitous downward inclination for North America, as can be seen in table II.8.

84. Growth of the Indian population apparently resumed slowly, estimated by Rosenblat (in millions) at 2.6 in 1825, 13.5 in 1940 and 14.9 in 1950.<sup>174</sup> European immigration and concomitant natural increase contributed substantially to this growth in many countries, notably in Argentina. The importation of African slaves, continuing until the middle of the last century in places, also swelled the numbers of inhabitants.<sup>175</sup> Brazil's population, according to one estimate, doubled between 1800-1850, increased by 149 per cent in 1850-1900 and by 189 per cent in the next fifty years.<sup>176</sup>

85. Among the major regions, Middle and South America currently appear to have the fastest rate of population growth in the world. Separate estimates at fifty-year intervals prepared for four component areas show that Brazil's high growth trend has been pre-eminent during the entire period 1750-1950, slightly exceeding the pace in the Caribbean. Growth elsewhere has been relatively moderate, with Mexico increasing more slowly than the remainder of Latin America.<sup>177</sup>

86. A continuation of very high fertility in nearly all Latin American countries appears from a tabulation of natality rates for the periods 1945-1950 and 1955-1960. Exceptions are Argentina and Uruguay, where crude birth rates are in the low 20s, Cuba in the low 30s and Chile slightly higher.<sup>178</sup> Puerto Rico's rates have also fallen below 30 in recent years (see also chapter IV, table IV.6). The downward trend in mortality, which is expected to continue for some time, will further inflate the already high rates of natural increase unless accompanied by lowered fertility. Rates of natural increase around 35 in the mid-1960s are reliably reported for Costa Rica, El Salvador and Mexico,<sup>179</sup> while estimates for several other countries for 1959-1961 range from around 22, as in the case of Bolivia, where mortality appears to be particularly high, to 35 or above, of which Venezuela is an example.<sup>180</sup> For the region as a whole,

there has been a doubling of the population in the thirty years from 1932 to 1962, when it reached an estimated total of 216 million.<sup>181</sup>

## 5. OCEANIA

87. Extremely high rates of both total and natural increase occurred in Australia and New Zealand in the third quarter of the nineteenth century, due in part to the influence of contemporary immigration and the resulting abnormal age structure of the population. Beginning in the late nineteenth century and through the 1930s, these countries experienced some decline in natural increase resulting from lowered fertility. The years following the Second World War have seen a recovery, as in the case of New Zealand, to a level approximating that of the early years of this century. A level of fertility higher than for most countries of western Europe has been retained while death rates have further decreased from a comparatively low level. With the exception of the war years, immigration has continued on a substantial scale.<sup>182</sup> Since the end of the Second World War, intercensal average rates of increase have ranged from 2.1 to 2.4 per cent *per annum*.<sup>183</sup>

## 6. ASIA

88. The outline of Asian demographic history is defined by that of China, India and Pakistan, which in 1965 accounted for 70 per cent of Asian population, and 40 per cent of that of the world. Beginning about the second quarter, the seventeenth century in China was a period of political and economic dislocation and great peasant rebellions. These wars in their destructive effects have been compared to the Thirty Years War in Europe.<sup>184</sup> After the overthrow of the Ming dynasty in 1644, the new Ch'ing Empire was consolidated only after further warfare, but sometime around 1700 the population may have approximately regained the size it had in 1600, about 150 million. Economic evidence as well as estimates derived from incomplete enumerations and registrations indicate that a period of sustained growth then began which continued into the nineteenth century. Totals have been suggested of 200 million for 1750, 323 million for 1800 and 430 million for 1850. Over the span of this period, therefore, it is likely that the number of inhabitants at least doubled. The rate of growth is conceived of as having slackened in the first half of the nineteenth century.<sup>185</sup> The remainder of the century was marked by the

<sup>173</sup> Davis, "The place of Latin America ..." (1964), p. 22.

<sup>174</sup> Rosenblat, *La población indígena* ... (1954), p. 122.

<sup>175</sup> Brazil's slave population has been put at 1 million in 1800, and about 1.5 million in 1860, according to Furtado, *The Economic Growth of Brazil* ... (1963), p. 127. Starting at the same figure in 1800 as Brazil, the slave population in the United States reached about 4 million, largely through natural increase. Poor diet and more intensive labour contributed to high slave mortality in Brazil, where deaths far exceeded births. This sector therefore was replenished continually by fresh imports. *Ibid.*, p. 129.

<sup>183</sup> United Nations, *Demographic Yearbook*, 1962 ... (1963), p. 283.

<sup>184</sup> Ho, *Studies on the Population* ... (1959), p. 265.

<sup>185</sup> Durand, "The modern expansion ..." (1967), p. 137. The totals derived from a study of Ch'ing Empire annual population reports lie within ranges estimated at 180-234 million for 1750, 290-360 million for 1800, and 390-480 million for 1850, *ibid.*, p. 138; they are in virtual agreement with the assessments of Ho, *Studies on the Population* ... (1959), p. 270, who also includes a discussion of the source material, pp. 47-64. See also Taeuber and Wang, "Population reports of the Ch'ing dynasty" (1960), pp. 403-417.

ravages of the T'ai P'ing Rebellion (1851-1864) and other upheavals and calamities of such severity that many areas suffered depopulation,<sup>186</sup> and by the end of the century the population size was apparently no larger than it had been fifty years before.

89. This total of 430 million for 1900 has also been calculated as a medium variant within a range of 385-494 million by backward extrapolation from the 1953 census figure of 583 million, assuming an average annual growth rate of 0.5 per cent.<sup>187</sup> The reliability of this census has not been established, but it is generally accepted as the best source for an insight into recent levels.<sup>188</sup>

90. Growth rates over fifty-year periods in the territory of modern India and Pakistan, in contrast to those of China, show a consistent trend of acceleration. The first total count of this area was carried out during 1867-1872, but it is usually assigned to the year 1872. A result of 203 million was officially raised to 233 million to rectify under-enumeration and omissions of area. A later study proposed 255 million as closer to the fact.<sup>189</sup> Estimates for this component included in the medium estimates for Asia in table II.4, at fifty-year intervals beginning 1750, are (in millions): 190, 195, 233, 285 and 434. For 1800 and by extension to 1750, a high variant of 214 million was reached by backward extrapolation from the total of 255 million, mentioned above, at the rate of 0.25 per year. A low variant of 160 million was derived from the application of a constant rate of decennial increase of 5.84 per cent postulated in a recent study.<sup>190</sup> From 1921, there has been a quickening of the upward trend, most pronounced in Pakistan. Adjusted data give intercensal rates of 1.0 per cent for 1921-1931 and 2.2 for 1951-1961 for this country, and corresponding rates of 1.1 and 2.0 for India.<sup>191</sup>

91. In its population growth trend, Japan has differed markedly from its Asian neighbours, both in the historical past and currently. As a frontier island in Asia, it appears to have had a growing population with expanding trade and colonization over a long period prior to its policy of isolation. The Tokugawa period (1600-1868) roughly corresponded with the sealing off of the country from all external relations, and during its early years there was a continuing increase in population. Thereafter, the level appeared to be stabilized according to official records dating from 1726 to 1852. The number of commoners

ranged only between 26.5 million in 1726 to 27.2 million in 1852, with minor fluctuations to a low of 24.9 in 1792 and a high of 27.2 in 1828 as well. An estimate of total population required the addition of the excluded classes—the Imperial household, the nobility, military, and lords and their establishments at one end of the social scale, and those at the bottom of the scale such as beggars, prostitutes, homeless persons—thought by some to approximate 1.5-2.1 million and by others about 4.0 million. This “presumed stability” masked compensating regional variations and fluctuations, however.<sup>192</sup> There is some disagreement among scholars as to the relative importance of deliberate efforts as opposed to natural forces in checking growth in that era. Abortion is known to have been practised in the upper classes, infanticide was more prevalent among the peasants,<sup>193</sup> and famines, epidemics, earthquakes and other calamities were not uncommon.

92. After the Meiji restoration, the first survey, in 1871-1872, indicated a total population of 34.8 million,<sup>194</sup> and in 1920 the first census in the modern sense gave a total of 55.4 million.<sup>195</sup> Compared with other Asian countries, rates of population increase have been low in modern Japan, although not so low as in European countries.

93. According to official statistics, both death and birth rates were low in the 1870s and rose in the early Meiji period. Checking registered age groups by life table survival rates, one author has estimated that both rates were actually considerably higher, the death rate over rather than under 20, and the birth rate around 32 rather than 24. According to him, early Meiji growth was not associated with an increase in births, but with a slight decline in the death rate,<sup>196</sup> yet in 1920, the birth rate was higher than before, and it declined decisively beginning only after 1950. Whatever the course of mortality in the early Meiji period, the decline after 1920 has been rapid and continuous, as registered by a drop in the crude death rate from 25 in 1920 to about 7 in the 1960s.

94. There is general agreement as to population levels for the modern period of Japan at about 30 million for 1750 and 1800, 31 million for 1850, and 44 for 1900. The first increase at these intervals was registered for 1800-1850, an annual average of 0.1 per cent, followed by 0.7 for the next fifty-year period and 1.3 from 1900 to 1950 when the total was 53 million.<sup>197</sup> Like other industrializing societies, Japan has thus undergone a demographic experience involving falling birth and death rates,

<sup>187</sup> Durand, “The modern expansion ...” (1967), p. 147.

<sup>188</sup> Taeuber and Wang, “Questions on population ...” (1960), pp. 263-310. Aird, in “Estimating China's population” (1967), pp. 61-72, considers some of the problems presented by recent Chinese population data.

<sup>189</sup> Davis, *The Population of India ...* (1951), pp. 24-48.

<sup>190</sup> Durand, “The modern expansion ...” (1967), pp. 137-138, 148-149. See also Datta, “A re-examination of Moreland's estimate ...” (1960), p. 167. Datta based the rate of 5.84 on increase between 1881-1931. If the period is extended to include the more questionable results of the census of 1871, the rate becomes 5.14 per cent. Other estimates of population in the area of present-day India, and of deaths resulting from seventeen famines occurring in the nineteenth century, are given in Sen Gupta *et al.*, “Estimates of 19th century population ...” (1969).

<sup>191</sup> Gille, “Accélération démographique en Extrême-Orient ...” (1961), p. 643.

<sup>192</sup> Taeuber, *The Population of Japan* (1958), pp. 21-27.

<sup>193</sup> *Ibid.*, pp. 29-30.

<sup>194</sup> *Ibid.*, p. 44. Durand, “The modern expansion ...” (1967), p. 149, reports that the official estimate for 1885 (given as 37.5 million in Taeuber, *The Population of Japan* (1958), p. 46) may be about 1 million too low. Durand cites Japan, Institute of Population Problems, *Meiji Shonen Iko Taisho 9-nen ...* (1962).

<sup>195</sup> United Nations, *Demographic Yearbook, 1962 ...* (1963), p. 272. This total has been adjusted to relate to present territory; in the territory at the date of the census, i.e., including Okinawa, it was 56.0 million, and is given in Taeuber, *The Population of Japan* (1958), p. 60.

<sup>196</sup> Morita, “An estimation on the actual ...” (1963), pp. 48-49, 52.

<sup>197</sup> Durand, “The modern expansion ...” (1967), p. 137.

but its relatively low and controlled fertility at the outset distinguishes its demographic transition from that of most countries.

95. The population of Indonesia was estimated at 77 million for 1950. Official data, even when adjusted for deficiencies, give only an uncertain approximation of population for most years prior to 1961, when 96.3 million inhabitants were counted.<sup>198</sup> Backward extrapolations have been calculated on the assumption of growth rates of 0.2 per cent for 1750-1800 and 1.2 per cent thereafter, giving medium estimates of 12 million in 1750, 13 million in 1800, 23 million in 1850 and 42 million in 1900.<sup>199</sup>

96. For the remainder of Asia, estimated percentage rates of growth have been calculated which assume an unbroken upward trend, a pattern similar to that of India-Pakistan, but at a slightly higher level: 0.1 for 1750-1800, 0.5 for 1800-1850, 0.7 for 1850-1900, and 1.2 for 1900-1950.<sup>200</sup> A high rate of increase for Thailand in the early part of this century has continued on an ascending scale; between the censuses of 1947 and 1960 the population appears to have grown at the average annual rate of 3.2 per cent,<sup>201</sup> as it has for the Philippines between 1950 and 1960.<sup>202</sup> Intercensal growth for the Republic of Korea for 1955-1960 is likewise high, at an annual average of 2.9 per cent. Most recently, the trend of increase appears to have been accelerating. Around 1960, an annual percentage of near 3.2 is thought likely for the Republic of Korea, and as high as 3.5 for the Philippines, at which latter rate the number of inhabitants would double in twenty years.<sup>203</sup> The trend in rates of natural increase in China (Taiwan) may be of more import than the size of the country would warrant if it is indicative of the beginning of deceleration in this part of the world. Fertility declining faster than mortality is reflected in rates of natural increase which fell steadily from 37 per thousand population in 1952 to 27 in 1965 for China (Taiwan).<sup>204</sup>

97. For Iran and South-West Asia, where ancient civilizations had provided for flourishing populations, the demographic history is virtually unknown. However, the known facts of wars, famine and epidemic, and of continuous economic decline over a long period point to causes for a prolonged contraction in numbers of inhabitants. Indications of revitalization appeared in the

nineteenth century, when Iran's numbers increased from a probable 6 million to somewhere in the range of 9-12 million over the 100 years.<sup>205</sup> United Nations estimates show growth becoming more substantial from 1920 on: an estimated 21.5 million inhabitants in 1960 represented an increase of 30 per cent in the preceding decade.<sup>206</sup> For South-West Asia and Iran as a whole, United Nations estimates give average annual growth rates of 1 per cent for the 1920s, increasing to about 1.7 for the 1940s and 2.7 per cent between 1950 and 1960.<sup>207</sup> Iraq's population as traced from 1867-1947 almost quadrupled, from about 1.2 million at the beginning of the period to 4.8 at the end. For 1905-1935 there was a loss of momentum and even slight reversal of the ascending rate in the preceding period, then a resumption of rapid increase.<sup>208</sup> An estimate of 5.1 million is given for 1950.<sup>209</sup>

## 7. AFRICA

98. The demographic situation of North Africa has been similar, in general, to that of Asia. In Egypt, a new cycle of growth from the low level reached under Mameluke chieftains is said to have begun under Mohammed Ali (1805-1848). Unreliable estimates imply that the population doubled during this period. An estimate for 1800 gave the population as about 2.5 million.<sup>210</sup> For 1882, the first census total of 6.8 million has been officially revised to 7.6.<sup>211</sup> The census of 1937 gave a total of 15.9 million and the implied average annual increase for the period is about 12 per thousand. External migration has not been a factor in the growth of Egypt's population. Records since 1934 indicate that crude birth rates between 45-48 have been the rule and that there has been a steady lowering in the crude death rate from about 35 to 20 by 1960. A pre-war level of increase of about 14 per thousand fell during the war, then slowly rose to about 25 by 1959 as a result of decreased mortality.<sup>212</sup> In 1960, 26 million inhabitants were counted.

99. According to official statistics, the Moslem population of Algeria increased from 2.3 million in 1856 to 6.1 million in 1936, at an apparent average annual increase of 12 per thousand. The rate was about 23, however, for the five years preceding 1937, slowed during the war, then reasserted itself and again approximates that level. In Tunisia, recorded rates of growth are lower, markedly so in most recent years, and in Morocco higher, but the pattern has been similar.<sup>213</sup> The following average percentage increases have been used in calculating

<sup>198</sup> See Indonesia, Central Bureau of Statistics, *Statistical Pocket Book* ... (1947), p. 6; Oei, *Niederländisch-Indien* ... (1948). "medium" estimates for North Africa as a whole: 0.2 for 1750-1800, 0.5 for 1800-1850, 1.2 for 1850-1900 and 1.4 for 1900-1950.<sup>214</sup>

100. Lack of statistical data and even of written history have made the size of population of most of Africa south of the Sahara a subject for conjecture until the present day. Widely disparate assessments have been offered by early western explorers, missionaries and officials. The post-war period marks a new era for African demography, although even today the vital statistics of the region are generally not known from comprehensive registration.<sup>215</sup> The extensive migrations of labour which characterize the present transitional phase of African development increase the difficulties of demographic measurement and analysis. Censuses taken in newly independent States represent first attempts at enumeration of total African populations for much of the continent and indicate greater numbers than previously supposed. Estimates are therefore subject to a wide range of possibilities according to various hypotheses about relevant factors.<sup>216</sup>

101. In general, it seems clear that African population has been growing rapidly since the Second World War. Most improvements of available information have led to upward revisions of the estimated growth rate. A rate of 2.4 per cent annually was estimated for all Africa in 1963-1968, the highest regional rate being that in Northern Africa—2.7 per cent.<sup>217</sup>

102. Kuczynski thought that many West African territories had a larger population before European slave trading than in the 1940s, but he was less positive about East Africa.<sup>218</sup> He also believed that the population of former British West Africa remained stationary during the first quarter of this century, and that East African population declined somewhat.<sup>219</sup> Martin supports the view that East African population before the First World War had changed very little over a century, and believes that it declined somewhat in the first quarter of this century, and then increased during 1930-1948 by rates in the range of 5 to 15 per thousand.<sup>220</sup> Growth has been least in Equatorial Africa, a region of low African fertility. In the Republic of South Africa, intercensal average annual rates of growth have been between 2.1 and 2.4 for the most recent period, except for 1911-1921 and 1936-1946. Total population had increased by 27 per cent between 1950 and 1960; Bantu population by almost 30 per cent and European by 18 per cent.

<sup>218</sup> Kuczynski, *Demographic Survey* ... (1948), vol. 1, pp. 13-14; vol. 2 (1949), pp. 120-122.

<sup>219</sup> *Ibid.*, vol. 1, pp. 13-15; vol. 2, pp. 122-123.

<sup>220</sup> Martin, "Estimates of population growth ..." (1961), pp. 50-53.

103. High natality serves the cultural requirements of the great variety of kinship systems that have been documented in African tribal society.<sup>221</sup> However, tribal customs governing marital relations and child care have usually been a deterrent to a realization of maximum fertility. Numerous explanations, in addition to the toll of endemic diseases, intertribal warfare of former times and famine, have been offered for the existence of areas of sparse settlement, relative low fertility, and probably depopulation. The incursions of the Europeans not only brought disease, but may have caused cultural shock and social disorganization which led to lowered fertility.<sup>222</sup> The relative importance of these factors affecting fertility is usually obscure. In most large tribal societies where contact with European population continued over a long period, the initial trend toward depopulation often experienced gave way to processes of adjustment, followed by a trend toward rapid natural increase.<sup>223</sup> Susceptibility to diseases introduced by Europeans may have been counteracted by the increasing practice of modern health measures.

#### E. Summary of regional trends, 1750-1965

104. The summary of rates of growth given in table II.8 as they relate to fifty-year periods for 1750-1950 indicate broad trends for major regions of the world. From a global viewpoint, population increased at a steady, modest pace until the first half of this century, after which a marked acceleration became apparent. The long-term trend was not uniform among regions, however, but embodied considerable variation. Decline was registered for North America, stability for Europe, fluctuations for the USSR and China, while for the remainder of Asia, and for Latin America and Africa a reflection of the steady over-all increase is found.<sup>224</sup>

105. This generally slow rise of the world trend, doubling its average rate of growth in 200 years, was broken by the spectacular acceleration apparent for 1950-1965. For these fifteen years, the rate was more than double that for the preceding fifty years. The number of inhabitants probably increased by about 70 per cent between 1800 and 1900 and by about 100 per cent between 1900

<sup>221</sup> Lorimer *et al.*, *Culture and Human Fertility* ... (1954), pp. 58-90, 118-125, 255-403.

<sup>222</sup> *Ibid.*, pp. 125-132.

<sup>223</sup> For review of evidence and bibliography on this subject, with reference to other regions, see Taeuber and Han, "Micronesian Islands under ..." (1950), pp. 93-115; see also Rosenblat, *La población indígena* ..., vol. 1 (1954), p. 121. The acculturation of tribal societies in India, where direct contact with Europeans has been largely limited to missionaries and administrators, does not seem to have involved any initial trend towards depopulation, but has led to generally high and rising rates of natural increase. See Sovani, *The Population Problem in India* ... (1942), pp. 204-207.

<sup>224</sup> Broad temporal and territorial scale unavoidably mask the fluctuations which are responses to a complexity of agents of short duration or localized impact. As stated by Glass, "Population and population movements ..." (1965), p. 238, "What is interesting is ... the short-period variation, the movement of ... fertility and mortality rates ... territorial distribution of population in different points of time ... social and other differences in fertility, and changes in marriage frequency and habits". For such a study relating to England in the period immediately preceding the Industrial Revolution, see Laslett, *The World We Have Lost* (1965).

SOURCE: Durand, "The modern expansion ..." (1967), p. 137; 1950-1965 rates computed from data in United Nations, *World Population Prospects as assessed in 1968* ...

and 1965, with an increase of 30 per cent taking place between 1950 and 1965. With the exception of Japan, all major regions of the world contributed to the most recent trend of expansion, including those regions where the former general trend of increase had reversed. This downturn appeared first in North America in the period 1850-1900 and next in Europe's moderate level in the following fifty-year period, signifying that declining fertility outbalanced a lengthening life span as industrialization transformed living conditions. The low rate for the USSR in the first half of the twentieth century may be ascribed in part to unusually heavy losses in a period that included two world wars. Thus, as Japan joined the ranks of the industrialized nations, from 1950 it also experienced the demographic transition from high to low mortality and fertility.<sup>225</sup>

106. Where the demographic transition first occurred, in countries of European settlement, wide gaps between gradually descending mortality and fertility rates did not develop. In general, the slow fall of mortality acted as a brake on population growth until the downtrend of fertility gained momentum. These countries and Japan combined (the more economically developed regions), had an average growth rate of 1.2 per cent for 1960-1965.<sup>226</sup> The remainder of the world, comprising about 70 per cent of the world's 1965 population, had a corresponding rate of 2.3 per cent. Here, the recent, relatively rapid decline in mortality is not a reflection of the technological advance which has been found to foster attitudes favouring smaller families; it rests upon the experience of the more industrialized societies in combating disease and famine. High birth rates have begun to give indications

of lowering in some instances, but a repetition of the intense and rapid industrialization which accompanied Japan's decline in vital rates has not yet appeared. Without this impetus to social change, the prospect appears to be one of continued rapid growth for some time to come. This prospect is discussed in chapter XV.

107. The scientific measurement of man's numbers has been attempted only in comparatively recent times, and as yet falls considerably short of total world coverage.<sup>227</sup> Acknowledging the imperfection of the information now available, it is nevertheless evident that the numerical expansion of the human race has been sporadic. There have been periods when populations grew at a comparatively rapid rate, others when they remained nearly stationary or experienced depletion. The periods of growth have not been synchronous in different areas. Diversity in the patterns of economic and social change has been matched by a diversity of population trends.

108. In earlier centuries, the pace of demographic growth appears to have been linked to the achievement of a social and political order which more or less successfully related population to the economic resources attainable. Populations were in the short run at the mercy of violent swings of mortality, but in the secular movements of population, fertility is likely to have been a major determinant of the trend, although the mechanisms for social control of fertility were, and to a large extent remain, of infinite variety and differ in their adaptability to changing conditions. There is no warrant in population history for a belief that until recently most of mankind subsisted in a uniform state of natural propagation, with a fertility close to the maximum level, passively responding to the changing toll of death.

<sup>225</sup> Relative levels of the two fundamental factors determining population change may be summarized broadly for the modern period in three demographic régimes: high fertility and mortality; high fertility and declining mortality; low fertility and mortality. The transition from one to another of these stages is discussed in chapter III.

<sup>226</sup> Rates computed from data in United Nations, *World Population Prospects as assessed in 1968* ...

<sup>227</sup> During 1855-1864, population censuses were taken in fifty-one countries and covered about 17 per cent of the world's population. Censuses taken in 1945-1954, which included that of China, counted about 78 per cent of the world; in 1955-1964, world coverage was about 67 per cent, when 202 countries had censuses, United Nations, *Demographic Yearbook, 1962* ... (1963), p. 1.

## Chapter III

### POPULATION THEORY

1. Man has been concerned with population problems since ancient times. From antiquity, statesmen and thinkers have held opinions, based on political, military, social and economic considerations, about such issues as the most desirable number of people or the need to stimulate or retard population growth. While these ideas were formulated with a view to public policy and only in exceptional cases went beyond mere speculation or incidental observations, the thoughts expressed foreshadowed many of the issues which would make their reappearance in modern population theory. Nevertheless, no consistent population theory emerged until the modern period.

2. While these early writings merit attention in that they anticipate aspects of the more formal population theory that was to develop later, modern population theory is generally considered to have its beginnings in the late eighteenth century writings of Malthus. His work stimulated interest in population and the economic and social issues associated with it, and pushed the subject into prominence for the first time. Malthus's work created controversy and that controversy spurred further investigation into demographic problems and stimulated continuing development in methods of observation and analysis. The literature dealing with population theory since Malthus's time is voluminous and therefore its review occupies most of this chapter.

3. As in the social sciences in general, ideas and theories on population have nearly always revolved round the real or supposed problems of individual societies and have stimulated the most response when directed specifically towards those problems. Thus the ideas of the philosophers of ancient Greece dealt mainly with the population questions faced by the city-state with a relatively small population. In the Roman Empire the views on population reflected the populationist outlook of a society in which population was considered a source of power. At the dawn of the modern era, the emergence of the nation-states and the related issue of power led mercantilist writers to emphasize once again the advantages, both political and economic, of a large population. Malthus's theory had its roots in political, economic and social issues which existed during his time. The same can be said of Marxist views on population. While other approaches to population theory—mathematical, biological, sociological—were formulated later, reflecting some of the major contemporary interests, more recent developments in population theories have been influenced predominantly by two factors. The first of these was the upsurge of population growth, especially in the developing

countries. Unprecedented in earlier history, this fact has created a need for a better understanding of the factors in population growth. Secondly, the nearly universal preoccupation with the problems of development called for a considerably more penetrating theoretical framework for assessing the interrelations between population and economic and social development. In this context, the search for an acceptable population theory has gained importance, not only because it would provide a better insight into the development process, but also because such a theory would constitute a basic element in development policy-making and planning.

#### A. Ancient and mediaeval writings on population

4. Germs of certain ideas which have figured prominently in recent theoretical works on population can be found in ancient writings. The thesis that excessive population growth may reduce output per worker, depress levels of living for the masses and engender strife is of great antiquity. It appears in the works of Confucius and his school, as well as in the works of other ancient Chinese philosophers. Some of these writings suggest that the authors had some concept of optimum population, as far as the population engaged in agriculture was concerned. Postulating an ideal proportion between land and population, they held the government primarily responsible for maintaining such a proportion by moving people from over-populated to under-populated areas, although noting also that government action was reinforced at times by spontaneous migration.

5. These ancient Chinese writers also paid some attention to another aspect which has occupied an important place in subsequent literature on population theory, that is, the checks to population growth. They observed that mortality increases when food supply is insufficient, that premature marriage makes for high infant mortality rates, that war checks population growth and that costly marriage ceremonies reduce the marriage rates,<sup>1</sup> although they paid little attention to the manner in which numbers adjusted to resources.<sup>2</sup> Despite these

views on population and resources, the doctrines of Confucius regarding family, marriage and procreation were essentially favourable to population increase.<sup>3</sup>

6. The writers of early Greece were more concerned with the formulation of policies and rules for population than with theories about it.<sup>4</sup> Plato and Aristotle discussed the question of the "optimum" population with respect to the Greek city-state in their writings on the ideal conditions for the full development of man's potential. They considered the problem of population size not so much in economic terms, but more from the point of view of defence, security and government. The thought was that population should be self-sufficient, and thus possess enough territory to supply its needs but not be so large as to make constitutional government impossible.<sup>5</sup> The more specific observations on these conditions were made by Plato, particularly in his *Laws*. He held that if the so-called "highest good" was to be achieved, the city-state should have 5,040 citizens. Since the actual course of demographic trends might result in either an excess or a shortage of population, Plato also proposed measures to be taken in order to maintain the desired size. In the case of under-population, he recommended rewards, advice or rebuke to the young in order to increase the birth rate, and, in the last resort, immigration. To remedy over-population he proposed birth control for large families and, if necessary, colonization.<sup>6</sup> Aristotle dealt with population problems particularly in his *Politica*. He was less specific than Plato on the matter of optimum population but stated that in size and extent the State should be such as to enable the inhabitants to live at once temperately and liberally in the enjoyment of leisure.<sup>7</sup> He held that land and property could not be increased as rapidly as the population would grow and concluded that an excessive number of inhabitants would breed poverty and social ills. Among the factors which could prevent an excessive population he mentioned child exposure and abortion.<sup>8</sup>

<sup>3</sup> Stangeland, *Pre-Malthusian Doctrines of Population* ... (1904), p. 46; Silberman, "Hung Liang-Chi: a Chinese Malthus" (1960), p. 257.

<sup>4</sup> Whittaker, *A History of Economic Ideas* (1946), p. 320. See also Cannan, *Wealth* ... (1928), p. 54; Hutchinson, *The Population Debate* ... (1967), p. 4.

<sup>5</sup> Stangeland, *Pre-Malthusian Doctrines of Population* ... (1904), pp. 18-28; Gonnard, *Histoire des doctrines de la population* (1923), chap. 2; Moreau, "Les théories démographiques dans l'antiquité grecque" (1949), pp. 597-614.

<sup>6</sup> Plato, *Laws* (c. 340 B.C., 1926 ed.), book 4, paras. 707-709; book 5, paras. 736-741; book 6, para. 754. Plato specified 5,040 as the number of citizens "most likely to be useful to all cities because it has fifty-nine divisors". A state with 5,040 citizens would have a total population of about 60,000. Plato, *Laws* (c. 340 B.C., 1926 ed.), book 5, paras. 737-738; and his *Republic* (c. 370-380 B.C., 1930 ed.), book 2, para. 372; book 4, para. 423; book 5, paras. 459-461. See also Welles, "The economic background of Plato's communism" (1948); Whittaker, *A History of Economic Ideas* (1946), pp. 320-321.

<sup>7</sup> Aristotle, *Politica* (c. 354 B.C., 1932 ed.), para. 1326 b.

<sup>8</sup> Aristotle, *Politica* (c. 354 B.C., 1932 ed.), book 2, paras. 6-9; book 7, paras. 4-5, 16. Aristotle thus proposed some of the ideas later advanced by Malthus, but von Bortkiewicz did not consider him a forerunner of Malthus. Bortkiewicz, "War Aristoteles Malthusianer?" (1906). For a somewhat different view, see Moissides, "Le Malthusianisme dans l'antiquité grecque" (1932); Himes, *Medical History of Contraception* (1936), chap. 4.

7. The Romans viewed population questions in the perspective of a great empire rather than a small city-state. They were less conscious than the Greeks of possible limits to population growth and more alert to its advantages for military and related purposes. Perhaps because of this difference in outlook, Roman writers paid less attention to population than the Greeks. Cicero rejected Plato's communism in wives and children and held that the State's population must be maintained by monogamous marriage.<sup>9</sup> The preoccupation with population growth, the disapproval of celibacy and the view of marriage as primarily and fundamentally for procreation was mainly reflected in the Roman legislation of that time. Particularly the laws of Augustus, creating privileges for those married and having children and discriminating financially against those not married, aimed at raising the marriage and birth rates.<sup>10</sup>

8. The Hebrew sacred books placed much emphasis on procreation and multiplication and, for this reason, unfruitfulness was regarded as a serious misfortune.<sup>11</sup> In general Oriental philosophers appear to have favoured fertility and multiplication.<sup>12</sup> An exponent of some of the views on population for the period dating back to some three to four centuries B.C. is Arthashastra, a book written as a guide for rulers and attributed to Kautilya. The work discusses such aspects as the desirability of a large population as a source of military and economic power (although recognizing that the population may become too large); the effects of war, famine and pestilence, and the colonization and settlement of new areas.<sup>13</sup>

9. Early and mediaeval Christian writers considered questions of population almost entirely from a moral and ethical standpoint. Their doctrines were mainly populationist but less so than those of Hebrew writers. On the one hand, they condemned polygamy, divorce, abortion, infanticide and child exposure; on the other hand, they glorified virginity and continence and frowned upon second marriage. The main arguments in favour of celibate practices are found in the teachings of Paul.<sup>14</sup> Some early Christian defenders of ecclesiastical celibacy resorted to economic arguments not unlike some of those later used by Malthus. Referring to the growth of the known world's population, they attributed want and poverty to this cause and cited pestilence, famine,

<sup>9</sup> Cicero, *De re publica* (c. 44 B.C., 1928 ed.), book 4, para. 5. Cicero, *De officiis* (c. 44 B.C., 1913 ed.), book 2, para. 5 listed various checks to population growth—floods, epidemics, famine, wild animals, revolution—but did not attempt to state a general theory of the determinants of population change.

<sup>10</sup> Stangeland, *Pre-Malthusian Doctrines of Population* ... (1904), pp. 29-39; Gonnard, *Histoire des doctrines de la population* (1923), chap. 3; Whittaker, *A History of Economic Ideas* (1946), p. 322; Hutchinson, *The Population Debate* ... (1967), p. 8.

<sup>11</sup> Passages of the Old Testament relevant in this respect are: Genesis, i, 28; xxviii, 14; xxx, 1-28; Deuteronomy, xxvi, 5; Proverbs, xiv, 28; xvii, 6; Psalms, cxxvii, 3-5; Ecclesiastes, iv, 8; Jeremiah, xxii, 30.

<sup>12</sup> Stangeland, *Pre-Malthusian Doctrines of Population* ... (1904), chap. 2.

<sup>13</sup> Kautilya, *Arthashastra* (1956); Spengler, "Arthashastra economics" (1963).

<sup>14</sup> See I Corinthians, vii; Romans, ix, 13; Colossians, iii, 5; I Thessalonians, iv, 3; I Timothy, v, 11-14.

war, etc., as nature's means of reducing excess population.<sup>15</sup> The prevailing tendency, however, was to favour, as in earlier times, population growth. The high mortality which was found everywhere and the constant threat of sudden depopulation through famine, epidemics and wars predisposed most writers towards the maintenance of a high birth rate. The opposition to birth control, for instance, was founded not only on church doctrine but also on a fear of depopulation.

10. The views of Moslem authors on population resemble those of the Hebrew and Christian authors. Special mention should be made, however, of the interesting but long unrecognized work by Ibn Khaldoun, an Arab author of the fourteenth century. His opinions are noteworthy in two respects. In the first place, he held that a densely settled population was conducive to higher levels of living since it permitted a greater division of labour, a more effective use of resources and military and political security. Secondly, he maintained that a State's periods of prosperity alternate with periods of decline and that cyclical variations in the population occur in rhythm with these economic fluctuations. Favourable economic conditions and political order stimulated population growth by increasing natality and checking mortality. In the wake of these periods of economic progress came luxury, rising taxes and other changes which in several generations produced political decline, economic depression and depopulation.<sup>16</sup>

## B. Towards modern theory

11. The relatively short span between the late fifteenth and the late eighteenth centuries was a period of great change set in motion by the changes in man's attitudes brought about by the Renaissance. This period witnessed the emergence of the nation state, new scientific discoveries, the exploration of new territories, and the rapid growth of trade, the gradual dissolution of the mediaeval feudal system and the development of early capitalism which laid the basis for the Industrial Revolution. The combined influence of these events was reflected also in the evolution of economic ideas and the thinking on population.

### 1. MERCANTILIST, PHYSIOCRATIC AND RELATED VIEWS

12. The above-mentioned factors were important elements in the rise of mercantilism, a current of new ideas in political economy, which was greatly influenced by Machiavelli's and Bodin's theories of the absolutist State.<sup>17</sup> While the ideas of individual mercantilist and

<sup>15</sup> Theophilus, "Theophilus to Antolychus" (c. A.D. 170, 1867 ed.), book 2, para. 32; book 3, para. 6; Methodius, "The banquet of the ten virgins; or concerning chastity" (c. A.D. 270; 1869 ed.); Jerome, "Letter 22" (c. A.D. 384, 1893 ed.); Dionisius Exiguus, "Libri de creatione hominis" (c. A.D. 520, 1848 ed.); Tertullian, "De anima" (c. A.D. 200, 1870 ed.); Eusebius, "Oration in praise of Constantine" (c. A.D. 300, 1890 ed.).

<sup>16</sup> Quadir, "The economic ideas of Ibn Khaldoun" (1942); Issawi, *An Arab Philosophy of History* ... (1950), chap. 5; Rosenthal, *Political Thought in Mediaeval Islam* ... (1962), chap. 4.

<sup>17</sup> Machiavelli, *The Prince* (1513, 1963 ed.); Bodin, *Les six livres de la république* (1576). Both of them spoke of a large population as a source of strength. Hutchinson, *The Population Debate* ... (1967); Soule, *Ideas of the Great Economists* (1952), chap. 2.

cameralist writers diverged considerably and the term "mercantilism" continues to be interpreted differently<sup>18</sup> the central tenet was the power and wealth of the state, and, in particular, the accumulation of money and precious metals came to be considered by a number of these writers as the main objective of national policy. The principal means of attaining these goals of power and wealth were the expansion of foreign trade and the development of manufacturing. Mercantilist doctrine oriented towards economic policy, did not develop a population theory in a strict sense, although views on population occupied a prominent place in the mercantilist system.

13. Mercantilist ideas dominated economic thinking in most of Europe during much of the seventeenth and part of the eighteenth century. Some of the views expressed by the mercantilists are, however, already found in earlier writings, among them those of Botero. According to Botero, the strength of the state is to be found in its population and the predominance of industry over agriculture.<sup>19</sup> However, he also noted that population tends to increase to the full extent made possible by human fecundity, while the means of subsistence and their capacity to increase were limited and, therefore, imposed a ceiling on population increase. This limit on population growth manifested itself through poverty, which discouraged marriage, and through periodic calamities, such as wars and pestilence. Like some mercantilists later, Botero advocated the establishment of colonies which could help to absorb a surplus population and at the same time would strengthen the power of the state.<sup>20</sup>

14. Mercantilist writers in general stressed the advantages of a large and growing population and favoured policies aimed at stimulating population growth, including measures to encourage marriage and large families, to improve public health, to check emigration to other countries and to promote immigration especially of skilled workers.<sup>21</sup> Some mercantilists, like Child, Coke, Davenant

<sup>18</sup> See, for instance, Heckscher, *Mercantilism* (1935); Lipson, *The Economic History of England* (1947), vol. 3, pp. 3 ff.; Spengler, "Mercantilist and physiocratic growth theory" and his "Appendix to chapter I" (1960). The reasons for this diversity of views may in part be found in the circumstance that mercantilist ideas underwent an evolution during the relatively long period in which they played an important role in economic and political thinking. In addition, mercantilist writers were necessarily influenced by the conditions peculiar to their own countries. On this latter aspect, see Viner, "Power versus plenty as objectives of foreign policy ..." (1948).

and Bossuet, argued that wealth itself consists in the largest possible population,<sup>22</sup> while others, like Fortrey and Becher, stressed the combination of a large population and much money.<sup>23</sup> Even those mercantilist writers who did not pay much attention to population, usually considered a large population as an important element in the strength of the State.<sup>24</sup> The mercantilists saw both political and economic advantages in having a numerous population. Population was not only an important factor in the power of the State, but also played a role in increasing the State's revenue and wealth. These latter goals, it was argued, could be reached either by increasing the total income of the State or through a higher excess of national product over its wage costs. Both would be served by a larger population, since such a population would, supposedly through a large and growing labour force, simultaneously generate a higher income<sup>25</sup> and depress wage levels and thus wage costs.<sup>26</sup> Temple asserted that the density of population is the basis of wealth. He argued that when population is scarce, people can easily obtain their livelihood and that, as a result, they would become lazy. On the contrary, under conditions of high density, people would have to work hard to live, creating attitudes favouring economic activity and industry.<sup>27</sup> The benefits of a larger population and additional labour would be particularly great, according to most mercantilist writers, if they served to develop manufacturing. This since manufacturing rather than agriculture was supposed to yield increasing returns and because manufactured products could be exchanged abroad for precious metals—materials considered among the most important elements in a nation's wealth.

15. In general mercantilist writers were inclined to consider a large population desirable, but differences in degree and even in opinions existed. Various writers

recognized that the size of a country's population was determined by the amount of subsistence that could be produced at home or obtained from abroad.<sup>28</sup> Others held that a large labour supply was useful only if it could be employed or that the size of the population was determined by the employment that could be made available.<sup>29</sup> Spengler noted that populationist feelings were probably strongest in countries such as Germany and Spain which had experienced depopulation, but less so in France, Italy, and especially England, where even some apprehension at over-population was expressed. In addition he stated that populationists lost much of their support in the latter half of the eighteenth century when the view that the growth of subsistence governs that of numbers became generally accepted.<sup>30</sup> Some mercantilist and cameralist writers commented on a variety of factors affecting population growth, such as plagues, wars, climate, infecundity due to urbanization and other causes, vice, abortion, postponement of marriage, debauchery and mortality, the effects of emigration to colonies and of the immigration of skilled workers, but writers in this tradition did not, on the whole, attempt a systematic explanation of population changes and their causes.

16. The physiocratic school of thought was in part a reaction against the ideas and policies proposed by mercantilist writers, and consequently opposed state intervention, trade regulation and other aspects of mercantilist thinking. The fundamental concept in the physiocratic thinking, according to Gide and Rist, was the "natural order" and within this system the economic aspect which stood in the foreground was the role of land in production.<sup>31</sup> Unlike the mercantilists, the physiocrats found the agricultural sector to be most strategic: the growth of the entire economy was supposed to be governed by the increase in agricultural produce. The physiocrats did not accept the populationist tenets of the mercantilist writers, in particular they did not agree with the mercantilist policy of increasing population even at the expense of levels of living. Nevertheless, they took a generally favourable view of population growth, on the condition that it was possible to expand agricultural production to support the increasing population. Some of the physiocrats were optimistic in this respect, others had a more pessimistic opinion.

17. Some of the ideas of the physiocrats were shared by Cantillon, who in other respects, can be considered a mercantilist writer. He believed that land was the main factor determining wealth, and that population would be limited by the amount of subsistence which could be

<sup>28</sup> Becher, *Politische Diskurs von den eigentlichen Ursachen* ... (1688).

<sup>30</sup> Spengler, "Mercantilist and physiocratic growth theory" (1965); According to Petersen, *The Politics of Population* (1964), p. 30, mercantilist writers never were able to reconcile their desire for a large population with the existence of "overcrowding" as shown by a high incidence of vagrancy and crime.

<sup>31</sup> Gide and Rist, *Histoire des doctrines économiques* (1947), vol. 1, pp. 6-13; Soule, *Ideas of the Great Economists* (1952), chap. 3.

produced on the land. In his explanation of population trends Cantillon distinguished between people living at the subsistence level where maximum population size was determined by the amount of subsistence available, and the wealthier classes, such as royalty, landowners etc., accustomed to a certain level of living and willing to give up or postpone marriage in order to maintain that level.<sup>32</sup>

18. The best-known among the physiocrats, Quesnay, thought that a large population was desirable, but under the condition that people must live comfortably. He stressed in maxims XXV and XXVI of his *Tableau*, that more emphasis should be given to the increase of wealth than to that of population. In his opinion, population tends to overtake the means of subsistence. As evidence he cited that there were always people who live poorly and in want. Although he noted that colonies might serve as outlets for excessive population, he and his followers stressed the increase of agricultural production and net product, and not the increase in numbers, as the proper objective.<sup>33</sup> Mirabeau considered a large population desirable, but emphasized also that population is dependent on food supply and that agriculture should be encouraged in every conceivable manner.<sup>34</sup> Mercier de la Rivière also believed in the dependence of population on the means of subsistence, but thought that when governments promoted the best possible ways of cultivation, the increase in production would outpace that in population.<sup>35</sup>

19. The optimism of the eighteenth century writers concerning the possibilities of feeding a growing population reached its peak at the time of the French Revolution.<sup>36</sup> Two writers are worthy of special note: Godwin, a philosopher and social reformer, and Condorcet, a mathematician and philosopher. Godwin had boundless faith in science; he declared that scientific progress would multiply the food supply to the point where a man would have to work only one half hour daily to satisfy all his needs. He did not think that the abundance thus created would lead to over-population, since man's reason was strong enough to curb sexual desire and procreation. He ascribed the poverty of the people and the vices of the society of his time mainly to the inequalities imposed by the social institutions.<sup>37</sup> Condorcet professed the same

faith in the power of science and in the future of human society: science would be able to prolong the life span without any worsening of the human condition through a production of food which would reach unsuspected heights and also because reason would come in to play to prevent irrational population growth.<sup>38</sup>

## 2. POLITICAL ARITHMETIC

20. The period between the late fifteenth and late eighteenth century saw not only a significant evolution of the views on population, but witnessed also the beginnings of the systematic measurement and analysis of population trends. Graunt in his *Natural and Political Observations on the Bills of Mortality* . . . , published in 1662, was the first to discern an underlying order in vital statistics. Using mainly the "bills of mortality" of the City of London, which were reports on burials and incidentally other events such as births, he observed the numerical regularity of a variety of demographic phenomena. He studied such matters as the sex ratio at birth; the relation between burials and christenings in London comparing it with that in a rural parish; the frequency of births and deaths in relation to population; the ratio of births to weddings as an index of fertility, etc. In addition, he commented on such matters as migration to the city, the effects of war and emigration on the sex ratio; the excessive size of London; the future growth of the city and a schematic life-table design.<sup>39</sup>

21. Petty, with whom Graunt collaborated,<sup>40</sup> not only analysed some of the demographic aspects also dealt with by Graunt, but maintained that arithmetic could be applied to population, economic and "political" affairs and developed a "political arithmetic" which involved a more searching study of population in human affairs and is considered the precursor of modern demography. Petty stressed the importance of population as "human capital", calling labour "the Father and active principle of wealth, as Lands are the Mother". He also was the first to attempt an estimate of "human capital" as well as of income and is thought to be the first to have intro-

<sup>32</sup> Cantillon, *Essai sur la nature du commerce en général* (1755, 1952 ed.), chaps. 15-16, also held that if agriculture fell short of requirements, or was subject to diminishing returns, additional agricultural products could be obtained abroad in exchange for manufactured goods. (1662, 1939 ed.); Glass, "John Graunt and his natural and political observations" (1963); Lorimer, "The development of demography" (1959); Ptoukha, "John Graunt, fondateur de la démographie" (1937); Willcox, "Biographical sketches: John Graunt, Lemuel Shattuck, John Shaw Billings" (1940). A more complete life table than Graunt's was published thirty years later by Halley, "An estimate of the degree of the mortality of mankind . . ." (1693, 1942 ed.).

<sup>40</sup> According to some writers, Petty, rather than Graunt, is the author of *Natural and Political Observations* . . . (1662, 1939 ed.). See for this discussion Hull, ed., *The Economic Writings of Sir William Petty*, vol. 1 . . . (1899); Willcox, "Biographical sketches: John Graunt, Lemuel Shattuck, John Shaw Billings" (1940); Greenwood, *Medical Statistics from Graunt to Farr* (1948); Glass, "Graunt's life table" (1950); Strauss, *Sir William Petty* (1954), p. 188.

duced the division of the population and the economy into primary, secondary and tertiary activities.<sup>41</sup>

22. Around the middle of the eighteenth century the research initiated by Graunt and Petty was carried further by Süssmilch, who saw in the regular patterns in population movements and relations the divine hand of Providence which ruled human society. Noting the existence of a number of checks to population growth, he wrote that they might be means for preventing excessive population, and particularly could be considered as punishments. Süssmilch studied a great number of demographic factors and their interrelations including the sex ratio at birth and at later ages, the distribution of deaths according to age and cause of death, the relations between population and marriages, births and so forth. Apart from constructing the first life table for Prussia, he also analysed the effects of age at marriage, dissolution of marriage by death, the nursing of infants and other factors on fertility.<sup>42</sup> He noted, as did Gregory King and others,<sup>43</sup> that population grew in geometric progression and while he believed that under normal conditions it might tend to double approximately every century, he said that under certain conditions the period of doubling might be as little as forty-two years.

23. Most of the writers in this tradition held the prevailing populationist view, but nevertheless recognized that the means of subsistence determined population. Their major contribution is the fact that even with limited statistical data at their disposal and a lack of basic theoretical concepts and methods of analysis, they extended the horizons of thought in population theory by breaking down limitations imposed on it in earlier times.

### C. Malthus and his theory

24. The eighteenth century was a period of profound change in intellectual climate. These changes were to have a decisive influence on social and economic as well as population theory. As old religious and philosophical beliefs were abandoned under the influence of the enlightenment, the conviction grew that human institutions would be subject to a natural order, as scientific discoveries had shown was true in the physical world. However, ideas about the character of the "natural order" differed. Some, like Condorcet and Godwin, thought that the "natural" society was one in which all bounties of nature should be held in common and in which progress through science would be continuous. On rejecting these views, Malthus, writing in the tradition of his times, based his thinking on his own idea of necessary relations as established in his principle of population.

Instead of the egalitarian society in continual progress, he envisaged the inevitability of a class society with the poor condemned to live at the subsistence level.

25. The view that man's capacity to reproduce was unlimited, whereas that of producing his means of subsistence was limited, had already been proposed by such writers as Botero in the sixteenth century.<sup>44</sup> Wallace, writing around the middle of the eighteenth century, drew attention to the relatively short period in which population could double and contrasted it with the capacity for food production.<sup>45</sup> Similar views were also found in other parts. In the last decade of the eighteenth century, the Chinese writer Hung Liang-Chi noted that the increase in means of subsistence was not in direct proportion to that in population. He argued that while in the course of a century population can increase from five-fold to twenty-fold, the means of subsistence—because of the limitation of the land area—could increase only from three to five times.<sup>46</sup>

26. These ideas were most forcefully presented by Malthus. He was the first to develop a consistent and comprehensive population theory in relation to economic conditions and his writings exercised a great influence on population and economic theory. He developed his ideas on population mainly in his *Essay on the Principle of Population*, first published in 1798.<sup>47</sup> The first edition of his *Essay* was essentially a polemic directed against earlier writers who held more optimistic views concerning the possibilities of supporting an increasing population. Malthus criticized in particular Condorcet's conjectures regarding the perfectability of man, Godwin's system of equality, his allegation that the vices of mankind originated in human institutions. On his part, Malthus regarded the social institutions of his days as natural and inevitable, asserting "the absolute impossibility from the fixed laws of our nature, that the pressure of want can ever be removed from the lower classes of society" and that "the principal and most permanent cause of poverty has little or no direct relation to forms of government, or the unequal distribution of property". Having formulated the principle that man could increase his subsistence only in arithmetical progression whereas his numbers tended to increase in geometrical progression, Malthus replied to the optimism expressed by other writers that man's capacity to increase his means of subsistence was much less than his capacity to multiply and that the evils of over-population existed and had always existed. The history of mankind, according to Malthus, demonstrated that population always tended towards the limits set by subsistence and was contained within those limits by the operation of positive and

<sup>41</sup> Petty, *Political Arithmetick* ... (1691); and his *Verbum sapienti* (1665); Hull, ed., *The Economic Writings of Sir William Petty*, vol. 1 ... (1963), p. 154; Silberman, "Hung Liang-Chi; a Chinese Malthus" (1960), also mentions the existence of the eighteenth century Japanese writer, Toshiaki Honda, who had similar ideas.

<sup>47</sup> Malthus, *An Essay on the Principle of Population as it Affects the Future Improvement of Society* ... (1798).

preventive checks, which, with the exception of the deferment of marriage, would take the form of either "misery" or "vice".<sup>48</sup>

27. In the much revised and enlarged second and later editions of his *Essay* Malthus developed his theory further and examined at greater length the role of population as the principal cause of poverty.<sup>49</sup> The basic propositions he attempted to prove are stated as follows:

"1. Population is necessarily limited by the means of subsistence. 2. Population invariably increases where the means of subsistence increase, unless prevented by some very powerful and obvious checks. 3. These checks, and the checks which repress the superior power of population, and keep its effects on a level with the means of subsistence, are all resolvable into moral restraint, vice, and 'misery'."

After stating that strong impediments to population growth are constantly in operation, Malthus inquires what would be the natural increase of population, if left unchecked, and what would be the rate at which the means of subsistence can be increased. On this basis he derives his two basic propositions that population tends to double itself every twenty-five years, thus increasing in a geometrical ratio, while under the most favourable conditions agricultural produce increases each twenty-five years by an equal quantity, thus increasing only in an arithmetical ratio. He concludes that "Taking the whole earth ... the human species would increase as the numbers 1, 2, 4, 8, 16, 32, 64, 128, 256 and subsistence as 1, 2, 3, 4, 5, 6, 7, 8, 9. In two centuries, the population would be to the means of subsistence as 256 to 9 ..."<sup>50</sup>

28. In general, Malthus appears to assume diminishing returns from land.<sup>51</sup> While the ultimate check to population is then the lack of food resulting from the different rates at which population and food increase, there are operating, according to Malthus, other checks which keep population down to the level of subsistence. He classified these under two headings: the preventive and the positive checks. The former ones, being voluntary, arise from man's reasoning faculties which enable him to foresee distant consequences, and they include moral restraint, which consisted mainly of the deferring of marriage, and "vice", which could take the form of the prevention of the birth of children, extra-marital sexual relations and prostitution. The positive checks were

assumed to be extremely various and to include all factors which contributed in any degree to a shortening of the normal duration of life. Among them were epidemics, wars, plague and famine, all manifestations of "misery". Malthus asserted that although one or more of these checks operate in every country, there are only few cases in which population does not tend to increase beyond the means of subsistence.<sup>52</sup> Under these conditions, Malthus concluded, moral restraint, together with frugal conduct, was the only practicable and morally acceptable alternative to unrestrained population growth.<sup>53</sup> Since the increase of population is limited by the increase in the means of subsistence, the encouragement of marriage, as opposed to moral restraint, would be possible only at the cost of higher mortality. Likewise, the reduction of mortality due to one cause of death would increase mortality due to some other cause.<sup>54</sup>

29. Malthus reviewed conditions in various societies and countries in order to substantiate his thesis and concluded that the history of mankind validated his basic propositions.<sup>55</sup> Nevertheless, the lack of a more objective approach and a less restrictive interpretation made Malthus overlook the fact that the scheme he proposed was not inevitable, as proved by the experience of countries then in the process of, or on the threshold of, the industrial revolution.

30. Much of Malthus's influence on his contemporaries and of the controversy surrounding him did not derive directly from his "principle of population" but from his rigid views of society. Malthus's view that the conditions of the poorer classes could not be improved by a more equitable distribution of income is found especially in his discussion of the system of the so-called "poor laws" existing at that time in England. He asserts that such a system of relief for the poor, given the quantity of food available, would only have the effect of increasing the population, raising the price of provisions and especially impoverishing the labouring classes immediately above the poor.<sup>56</sup> These arguments became a political force in England during the first half of the nineteenth century when these measures were under discussion.<sup>57</sup> Malthus's rigid views of society caused violent attacks by the opponents of the existing order, thus complicating the controversy concerning his propositions regarding population.<sup>58</sup> As far as the latter are concerned, Malthus's writings constituted an important factor in the subsequent development of population theory. His "principle of population" by creating considerable controversy, made both his followers and opponents conscious of the need for a

<sup>48</sup> *Ibid.*, chaps. 2, 4, 7.

<sup>58</sup> Sauvy, *Malthus et les deux Marx ...* (1963), p. 38, notes that Malthus in his theory introduces an element of the class struggle. See also Myrdal, *Population: A Problem for Democracy* (1940, 1962 ed.), pp. 14-17.

better understanding of population trends and their relations with social and economic conditions.

#### D. The classical and neo-classical schools of economics and population theory

31. The evolution of population theory during the first half of the nineteenth century was largely dominated by two developments. One of these was the incorporation into the theory of the "classical school" of Malthus's population principle, thus placing it in the context of a theory of economic growth. However, during the same period, Malthus's views were becoming increasingly criticized within the context of traditional economic thinking as well as by non-economists.<sup>59</sup>

##### 1. MALTHUS'S POPULATION THEORY AND THE THEORY OF ECONOMIC GROWTH OF THE CLASSICAL SCHOOL

32. The "classical school" did not constitute a school of thinking in the usual sense of the word.<sup>60</sup> The unifying element in the views of these writers was their concern with the "laws" governing the levels and trends of production and its distribution among wages, interest, rent and profits. However, fundamental differences existed among the classical economists concerning their opinion about the outlook for future economic growth. While some of them were optimistic in this respect, most took a more pessimistic view. Basing themselves on the Malthusian theory of population and the "law" of diminishing returns, they derived their theory of the "stationary state" which pretended to explain how, through the interaction of the forces involved, economic growth would come to a standstill under equilibrated conditions and a stationary population and income.<sup>61</sup>

33. The law or principle of diminishing returns had already been advanced by Serra, Stewart and Turgot. Diminishing returns, however, were thought to be typical for agriculture only, whereas industry, with the possibilities it offered for increasing the division of labour and continued technological improvement, was assumed to be working under either constant or increasing returns. Decreasing returns in agriculture were expected, at least beyond a certain point, because, first, the quantity and quality of land were fixed and, secondly, the opportunities for a far-reaching division of labour and technological progress were limited in agriculture. In the absence of the latter, the fixed quantity and quality of land meant

that in the long run agricultural production could be expanded only by resorting to land of inferior quality with lower returns to labour or by bestowing on land already in use additional labour—or additional labour and capital in a fixed proportion—which also after a given point would result in lower than proportionate increases in production.<sup>62</sup> Views as to the extent to which other factors might offset the trend towards diminishing returns in agriculture differed. Some writers qualified their opinion in the sense that they argued that with improvements in agricultural skills and in land tenure, returns in agriculture would not decline as rapidly as in their absence, but they conceded that decreasing returns were bound to prevail if population continued to grow.<sup>63</sup> Others recognized that increasing returns might prevail in industry, but thought that the extension of the division of labour and technological progress in the non-agricultural sectors could not in the long run compensate for the diminishing returns in agriculture, partly because industries depended on raw materials from that sector.<sup>64</sup>

34. Malthus's proposition that population was limited by the means of subsistence and that, in the absence of checks, population would increase when these means increased, was incorporated in the theory of wages of the classical school. According to this, wages tended towards a level which was just necessary to enable the labourers to subsist and "to perpetuate their race without either an increase or decrease".<sup>65</sup> This wage theory held that at the so-called subsistence wage level,<sup>66</sup> the supply of labour would be completely elastic. If wages were above the subsistence level—and the means of subsistence of the workers were above the minimum level for any length of time—population and labour supply would tend to reproduce at a more rapid rate in accordance with Malthus's theory and the increased supply of labour would tend to bring wages down again to the subsistence level. Likewise, if wages were below the subsistence or natural price, population would decline; but in response

<sup>59</sup> Some of the severest criticisms of Malthus's theory came from the pre-Marxian socialists, but since the socialist ideas on population were only fully developed by Marx around the middle of the century, they are dealt with in the section on Marxist views on population.

<sup>60</sup> No unanimity exists as to what writers should be considered as belonging to the classical school. Usually Smith, Ricardo, Malthus, Say, West and James Mill are considered among its main contributors.

<sup>61</sup> Since the different writers in this school did not share identical views, nor develop their analyses in all detail, this is a synthetic view of the theory of the classical school developed mostly by modern economists. Baumol, *Economic Dynamics* ... (1951), pp. 11-19; Meier and Baldwin, *Economic Development* ... (1957), pp. 34-39; Higgins, *Economic Development* ... (1959), pp. 95-99; Adelman, *Theories of Economic Growth and Development* (1961), chaps. 3-4.

<sup>62</sup> West, *Essay on the Application of Capital to Land* ... (1815), p. 7; Ricardo, *Principles of Political Economy and Taxation* (1821, 1933 ed.); Mill, *Elements of Political Economy* (1821); Senior, *An Outline of the Science of Political Economy* (1836); Malthus, *Principles of Political Economy* ... (1836); Mill, *Principles of Political Economy with Some of Their Applications to Social Philosophy* (1848); McCulloch, *Principles of Political Economy* ... (1825), part 3, chap. 6; Say, *Traité d'économie politique* ... (1826), book 1, chap. 1. The formulation of the concept of diminishing returns by the writers of the classical school was not always very rigorous and concise, although the essential elements of the principle were contained in their ideas.

<sup>63</sup> Senior, *An Outline of the Science of Political Economy* (1836), pp. 26 ff., 81-86, thought that even then there would be no reason for alarm, as long as food could be imported in exchange for manufactured products.

<sup>64</sup> Mill, *Principles of Political Economy with some of Their Applications to Social Philosophy* (1848), book 1, chaps. 10-13; Ricardo, *The Principles of Political Economy and Taxation* (1821, 1933 ed.), chap. 31.

<sup>65</sup> Ricardo, *The Principles of Political Economy and Taxation* (1821, 1933 ed.), chap. 5.

<sup>66</sup> The concept of subsistence wage is not a completely unequivocal concept. Some of the contemporary writers regarded it as the wage necessary to satisfy the purely biological requirements, as in the case of Ricardo; others believed that the subsistence wage was, at least in part, socially or culturally determined.

to the resulting labour shortage, wages and population would rise again, tending towards the equilibrium level.

35. The two basic principles of classical doctrine, diminishing returns and the pressure of population on subsistence, were, together with the theory of accumulation, at the core of the long-run view of economic growth of the classical school. This led to the stationary state of the economy and the population.<sup>67</sup> Like most economists since, the classical economists took it for granted that profit was the motive force in economic growth and particularly in capital formation. As long as additional investments were expected to produce profits, capital accumulation would continue and so would the demand for labour. As a result of the latter, wages would remain above the subsistence level and induce population to grow, as postulated in the Malthusian theory. From a certain point on, due to the fixed quantity of land, diminishing returns would set in and profits and wages would decline. This process would continue until the point was reached where wages reached their lowest level—the subsistence level—and profits would disappear. This would also be an equilibrium situation, since with wages at the subsistence level, population would not grow further and with the disappearance of profits, capital accumulation would come to an end and income would stabilize.

36. Although most of the classical economists as well as their successors considered it likely that ultimately, economic growth—and with it population growth—would come to an end, only a few regarded the stationary state as imminent or absolutely inevitable. In fact, Smith did not share the pessimistic view of the later classical economists and he thought that under favourable conditions the propensity to “truck and barter” would cause ever-increasing specialization, improvement in technology and expanding markets.<sup>68</sup> A growing population, according to Smith, by widening the market and fostering inventiveness, facilitated the division of labour. Increasing division of labour would produce greater productivity, a larger revenue and stock which would produce an enlarged wage fund, an increased demand for labour and, thus, economic conditions favourable to population growth. Everett subscribed to the idea that an increase in population would produce “a division of labour and a consequent increase of skill in its application”. The result of this was, he said, an extension of manufacturing and trade, with a rise in wages due to the increasing productivity of labour.<sup>69</sup> Senior believed that there was a natural tendency for subsistence to increase at a greater ratio than population.<sup>70</sup> Carey stressed what

he called “the power of association” which grew as population increased and made possible greater diversity of employment, greater development of the human faculties, and increasing *per capita* output.<sup>71</sup> Some of the early American critics of the classical theory and Malthusian views in particular, argued that increasing population density would increase the division of labour.<sup>72</sup> Ricardo, whose views were among the most pessimistic, considered it possible that the natural tendency of profits to fall, leading to stagnation, could be checked by “improvements in machinery” and discoveries in “the science of agriculture”.<sup>73</sup> He also noted that in a society improving because of capital accumulation, the market wage—that is the wage actually paid—might remain above the natural or subsistence wage rate and that the resulting demand for labour would give a continuous stimulus to population growth. J. S. Mill, although accepting Malthus’s principle of population and assuming the inevitability of the stationary state, stressed, among others, social reforms, improvements in education, progress in science and the state of the arts, the extension of specialization and more efficient economic organization as factors which could make for long-term economic progress. While arguing that countries like England could not indefinitely import food, he mentioned emigration as a factor in reducing but not solving population pressure.<sup>74</sup> Some other writers noted that the operation of the law of diminishing returns in agriculture could be weakened through international trade by exchanging manufactured for agricultural products or through emigration.<sup>75</sup>

37. In the theoretical framework of the classical school, population emerged as essentially a dependent variable, the supply of labour being considered perfectly elastic at the subsistence level of wages.<sup>76</sup> This point of view is expressed by several of the classical economists. According to Smith, “the demand for men like that of any other commodity necessarily regulates the production of men”.<sup>77</sup> Ricardo maintained that population “regulates itself by the funds which are to employ it and, therefore, always increases or diminishes with the increase or diminu-

<sup>67</sup> The description of the mechanism by which a progressive state developed into a stationary state is mostly based on modern interpretation of classical theory. Harrod, *Towards a Dynamic Economics* ... (1963); Adelman, *Theories of Economic Growth and Development* (1961); Baumol, *Economic Dynamics* ... (1951); Higgins, *Economic Development* ... (1959).

<sup>75</sup> Senior, *Political Economy* (1836), pp. 26 ff., 81-86; Fawcett, *Manual of Political Economy* (1863), pp. 159-160, 249-250. This view was, however, not held by Mill, *Principles of Political Economy* ... (1848), book 1, chap. 13.

<sup>76</sup> McKinley, “The theory of economic growth in the English classical school” (1960).

<sup>77</sup> Smith, *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776, 1966 ed.). Gray saw in this statement a summary of Malthus’s theory. Gray, *The Development of Economic Doctrine* ... (1931, 1963 ed.), p. 135.

tion of capital”<sup>78</sup> Malthus’s proposition that the pressure of population on the means of subsistence would not engender an effective stimulus to the continued increase of wealth reflects the same opinion.<sup>79</sup> Other writers of the classical school like James Mill, Senior, and McCulloch held similar opinions.<sup>80</sup>

38. Nevertheless, the classical writers often not only qualified their theory of economic growth in the sense that technological progress might postpone the coming of the stationary state, but also their views on population in that they did not exclude the possibility that population growth might respond to other factors than the limits set upon it by the means of subsistence. Ricardo suggested the possibility of some form of voluntary population control in mentioning that the best security against overpopulation would be to stimulate “a taste for comforts and enjoyments” in the labouring classes.<sup>81</sup> A more moderate than usual formulation of the population principle by Senior, who asserted that population was limited “only by the moral or physical evil or by the fear of deficiency of those articles of wealth which the habits of the individual have lead them to require”, suggests the existence of such control.<sup>82</sup> J. S. Mill, although supporting Malthus’s propositions that population could double in not much more than twenty years, made the important distinction between economically more and less advanced countries. Arguing that in the latter population would be checked by want and starvation, he also thought that in the more advanced societies population growth would be restrained by the fear of want and the desire for improved living conditions. The increase in numbers could be checked by means of the limitation of births, prompted by “prudence and foresight” and “conscientious self-restraint”. These motivations and practices were most evident among the middle classes according to Mill, but the gradual, though slowly increasing levels of living of the labouring classes would presumably lead to a spread of these practices also in the latter.<sup>83</sup>

39. Whereas English writers probably made the most significant contribution to the classical theory, the works of contemporaries in other countries merit attention because, although they held ideas similar to those of the former, on the whole they took a more optimistic view of the population problem.<sup>84</sup> In Germany, von Thünen, attributing low wages to the low marginal productivity of labour and the exploitation by employers, thought that both these conditions were mainly attributable to

the rapid growth of population but could be remedied by reducing the number of workers in relation to capital.<sup>85</sup> French economists like Say, Destutt de Tracy, Courcelle-Seneuil, Liesse and others called attention to the importance of the distribution of income as a factor affecting population growth. They contended, in general, that the size of a country’s population varies inversely with the *per capita* consumption, which in turn varies directly with the degree of inequality of income.<sup>86</sup> A similar view was put forward by von Storch, founder of the Germano-Russian school of economics.<sup>87</sup> Garnier defended the views held by Malthus, but he was more optimistic than the latter, believing that poverty could be prevented by prudence, capital formation, regulation of the family size and so forth.<sup>88</sup> Tucker, in America, although a disciple of Malthus, observed that the rate of natural increase of the population was declining.<sup>89</sup>

## 2. CRITICISMS OF MALTHUS’S THEORY BY NON-SOCIALIST WRITERS

40. The population theory of the classical school was challenged, apart from the socialists, by a number of contemporary writers. These criticisms of the classical economists may be divided into two categories: first, economic considerations stressing such factors as the technological progress, division of labour, expansion of production or trade which seemed to contradict the classical views on economic progress, wages and population, and secondly, demographic considerations in the true sense, especially the speculations and findings as to population trends and the evolution of the birth rates which tended to contradict the Malthusian and classical propositions on population.

41. Some indications that the trend towards the “stationary state” was not as immediate or as inevitable as it appeared are found, as already noted, in some of the writings of the classical school. Later critics of the theory of the classical school on economic growth placed more emphasis on the possibility of technical progress. Leroy-Beaulieu stated that technical progress, together with capital accumulation and the development of the international division of labour, would continue to increase output per man.<sup>90</sup> In the view of Oppenheimer, the continuing improvement in living conditions of the masses indicated that any tendency towards diminishing

<sup>88</sup> Garnier, *Du principe de population* (1857), chaps. 1, 4-11.

<sup>89</sup> See Dorfman, *The Economic Mind in American Civilization* ... (1946), pp. 178-195; Cady, “The early American reaction to the theory of Malthus” (1931); Spengler, “Population doctrines in the United States” (1933).

<sup>90</sup> Leroy-Beaulieu, *Traité théorique et pratique d’économie politique* (1896), book 1, pp. 740-776; book 3, p. 314.

returns in agriculture was more than compensated for by an improved productivity in manufacturing.<sup>91</sup>

42. Certain early nineteenth century writers disagreed fundamentally with the ideas of the classical school and held that a tendency for productivity to increase was predominant. Such writers either denied the law of diminishing returns altogether, or, while admitting its existence within agriculture, stated that its action was more than counterbalanced by a law of increasing returns outside agriculture, by technical progress, or by a combination of both. There were some writers who contended that an increase in population or population density made for an increase in productivity. A view along this line can be found in works of some of the writers of the classical school who were more optimistically inclined. Smith, for instance, regarded population growth as, at once, a cause and a consequence of economic progress.

43. The writers who disagreed with Malthus's arguments and propositions on population can be divided into three main groups.<sup>92</sup> One group maintained that preventive checks would become more and more important in slowing down population growth, though they offered little rationale to support this belief. Representatives of this group include Hazlitt, who supposed that moral restraint would prove adequate;<sup>93</sup> Hamilton, who held that the rate of increase of population would fall as civilization advanced;<sup>94</sup> Moreton, who inferred that the failure of the "higher orders" to replace themselves and the consequent opportunity for ascent in social scale generated a tendency for the lower rate of reproduction to spread through the ranks of society;<sup>95</sup> Weyland, who thought that population would cease to grow when a sufficiently high proportion of the people had located in cities where birth rates were lower,<sup>96</sup> as well as many other writers who presumed that the standard of living would continue to rise and check undue population growth.<sup>97</sup>

44. The second group of writers attempted to demonstrate that preventive checks were the result of social and economic progress. Such an opinion is even suggested

in Malthus's later work. Commenting on the situation in England, he noted that "this great increase over the necessities of life did not produce a proportionate increase of population". The result of a higher respect of the lower classes by others and by themselves was that instead of an increase in population exclusively, a considerable portion of their increased real wages was expended in a marked improvement in the quality of food consumed, and a decided elevation in the standard of their comforts and conveniences.<sup>98</sup> In addition to similar views already cited,<sup>99</sup> various writers like Rickards<sup>100</sup> and Alison<sup>101</sup> argued that as the real income of workers rose, they tended to adjust their standards of life accordingly, and that the higher standards, once attained, would not willingly be relinquished. As they became more self-respecting, workers would protect their position the more zealously by postponing marriage and limiting their families, as well as in other ways.

45. The third group of writers who rejected Malthus's population theory emphasized the reduction of natural fecundity which, they believed, would necessarily occur in the course of economic development as a result of social selection and changes in milieu. Some saw the reason for a decline of human fecundity in increased mental exertion, inbreeding and modifications of diet.<sup>102</sup> Spencer proposed a theory setting forth an antagonism between the power to maintain life and the power to propagate.<sup>103</sup>

46. Much of the criticism against Malthus, however, was based on the actual trends in population, which became better known, and, according to Blaug after the middle of the third decade of the nineteenth century no economist expounded the Malthusian theory without noting the empirical evidence that contradicted it.<sup>104</sup>

### 3. THE NEO-CLASSICAL SCHOOL AND POPULATION THEORY

47. Towards the close of the nineteenth century many of the assumptions on which the classical school had built its theory of economic growth and population were being increasingly questioned. The birth rate was declining in many western countries and in a number of them emigration was further reducing the impact of the natural increase of population, food imports offset the insufficiency of domestic agricultural production where necessary, and, most important, it was increasingly felt that technological progress, the increase in human skills and material productive wealth, and progressive social

<sup>91</sup> Oppenheimer, *Das Bevölkerungsgesetz des T. R. Malthus unter der neuen Nationalökonomie* ... (1901), chaps. 2 and 4.

<sup>92</sup> Various writers criticized the use of the geometrical and, especially, the arithmetical ratios by Malthus, but a number of them argued that they were not essential to the theory. See, for instance, Mill, *Principles of Political Economy with Some of their Applications to Social Philosophy* (1848); Cannan, *A Review of Economic Theory* (1929, 1964 ed.), p. 69; Roll, *A History of Economic Thought* (1950), p. 209; McCleary, *The Malthusian Population Theory* (1953), pp. 103-105. Some writers such as Sadler, *The Law of Population* ... (1830), criticized much of the evidence Malthus had cited supporting his hypothesis. See also Coontz, *Population Theories and the Economic Interpretation* (1957), pp. 22-28.

changes might counterbalance the tendency towards diminishing returns. In addition, neo-classical analysis focusing its attention mostly on short-run, static or methodological problems, was much more concerned with such aspects as the interrelations between parts of the economy, equilibrium theory and the allocation of resources than with the more general and long-run problems of economic growth and population.<sup>105</sup> Nevertheless the issues continuing to dominate the discussion on population and economic growth were basically the same as those raised by Malthus and the classical school.

48. The belief that other things being equal, diminishing returns were typical for the economy as a whole was accepted by a majority of economists in the late nineteenth and early twentieth century.<sup>106</sup> This implied that after the ratio of workers to resources passed a certain point, further population growth would bring with it a fall in the average output per worker. On the other hand most of these writers conceded that the *ceteris paribus* conditions did not apply in practice and that the appearance of diminishing returns, and by implication the effects of population growth on income, depended upon technological progress, the specialization and division of labour, the scale of the economy and the enterprise and so forth. Many of the writers who accepted the principle of diminishing returns thought also that through such changes the onset of diminishing returns could be delayed indefinitely or even offset completely.<sup>107</sup>

49. The view that increasing returns might predominate was held, especially by Marshall, who asserted that "while the part which nature plays in production shows a tendency to diminishing returns, the part which man plays shows a tendency to increasing returns".<sup>108</sup> In another place he wrote that even in agriculture the law of increasing returns was constantly contending with that of diminishing returns as a result of more careful cultivation, the development of roads, railroads and markets.<sup>109</sup> Increasing returns according to Marshall had their origin in the tendency of external economies, and to some extent internal economies, to increase as the aggregate volume of production increased. Such economies arose out of increased knowledge, greater specialization of labour and machinery, better localization of industry, the increasing scale of industry, more economic use of factors and materials, better and more time-saving

communications, more efficient marketing and other organizational improvements.<sup>110</sup> All of these changes could be associated with increases in the aggregate volume of production and, therefore, increasing returns might result from population growth as well as other factors which increased production.<sup>111</sup> Among the factors which generally might bring about increases in income per head, Marshall thus included population growth in so far as it stimulated or made possible the development of industry, gave rise to certain inventions and innovations and to various economies consequent upon the improvements in the organization.<sup>112</sup> He declared that an increase in population "accompanied by an equal increase in the material resources of enjoyments and aids to production" was likely to result in a more than proportionate increase of enjoyments of all kind, provided that an adequate supply of raw produce can be obtained without great difficulty and that there would not be such overcrowding as to impair health and recreation.<sup>113</sup> While he believed that the growth of population in the more advanced countries was, on the whole, advantageous, this would not be indefinitely so, nor was population growth, elsewhere in the world, necessarily a favourable factor. According to Marshall, continuing population growth would tend to have an adverse effect upon levels of living when a country's supply of land is limited so that the production from land is highly inelastic. In an old country where all cultivated land has been brought into use, diminishing incremental returns were likely to occur when no further improvements in the "arts of agriculture" took place. Under these conditions England's position, and presumably that of other countries in similar condition, might worsen because it might lose its leading industrial position, thus shrinking its foreign market for manufactured products exchanged for food and causing terms of trade to turn against her.<sup>114</sup> Because resources were limited, it was essential according to Marshall that premature and improvident marriage be avoided in order to avert a growth of population which would be evil.<sup>115</sup> The less

<sup>105</sup> See, for instance, on this point Schumpeter, *History of Economic Analysis* (1961); Whitney, "Population in theories of economic development" (1959); Buttrick, "Toward a theory of economic growth: the neoclassical contribution" (1965).

(1903), chap. 9; Wicksteed, *The Commonsense of Political Economy* (1910), p. 529; Edgeworth, *Papers Relating to Political Economy* (1925), vol. 1, pp. 79-80.

<sup>108</sup> Marshall, *Principles of Economics* (1920, 1961 ed.), pp. 318-321.

<sup>109</sup> *Ibid.*, p. 670.

<sup>110</sup> Marshall, *Principles of Economics* (1920, 1961, ed.), pp. 286 ff., 318-321, 396 ff., 457 ff.

<sup>111</sup> Spengler, "Marshall on the population question, part I" (1955), noted however, that Marshall did not clearly separate the effect of population growth and other factors upon increasing returns.

<sup>112</sup> *Ibid.* It is noteworthy that among the other factors which would raise levels of income, Marshall included improvements in the health, vigour, education and efficiency of the labour force.

<sup>113</sup> Marshall, *Principles of Economics* (1920, 1961 ed.), p. 321.

<sup>114</sup> Marshall, *Industry and Trade* ... (1919), pp. 647 ff.; Pigou, ed., *Memorials of Alfred Marshall* (1925), p. 316; Keynes, ed., *Official Papers of Alfred Marshall* (1926), pp. 401-402. The view that some European countries such as Great Britain and also Germany would have to rely to an excessive degree on foreign trade for obtaining food and that such imports might cease was propounded also by a number of other writers. See, for instance, Sidgwick, *The Principles of Political Economy* (1883), chap. 6; Giffen, *Economic Inquiries and Studies* (1904), vol. 1, pp. 382 ff.; vol. 2, pp. 14-27, 35-38, 46, 230, 340-344; Wagner, *Agrar- und Industriestaat* (1901), pp. 23-28, 143, 152-160. For different opinions, see Brentano, *Die Schrecken des überwiegenden Industriestaats* (1901); Dietzel, *Weltwirtschaft und Volkswirtschaft* (1900), pp. 112-120.

<sup>115</sup> Cited in Spengler, "Marshall on the population question, part I" (1955).

advanced countries could only escape the "iron" law of wages and attain levels of living comparable to the more advanced ones if their numbers were effectively regulated.<sup>116</sup>

50. Some writers took exception to the law of increasing returns as formulated by Marshall, while others argued that it minimized the problems of realizing the potential increase in efficiency and output that growth of capital and labour supply might seem to make possible.<sup>117</sup> Wicksell pointed out that the validity of Marshall's "law" depended on the assumption, which he considered unacceptable, "that the raw materials required are to be found in practically unlimited quantities at an unchanged, or almost unchanged, price". Although increasing returns might well prevail for a time, Wicksell thought that diminishing returns would predominate in the long run.<sup>118</sup> Wolfe pointed out that natural resources always set a limit to production, though that limit is somewhat elastic and faced by different countries at different times according to the availability and management of resources. Continuing population growth would therefore eventually bring the law of diminishing returns into operation, so that economic, social and political policy changes would be necessary to ensure continued progress in the material well-being of the people.<sup>119</sup> Budge held that the limitations to human progress were to be found in nature rather than in man's institutions, and that population was tending to increase beyond the means of subsistence. He denied that diminishing returns in agriculture would be offset indefinitely by improvements in agricultural technique or counterbalanced by increasing returns in manufactures and transportation, or that population increases caused *per capita* product to rise.<sup>120</sup> Wolfe drew attention to the various limitations to which technical progress itself is subject, thereby in effect denying the way of escape which many sought from the Malthusian problem. He identified four factors limiting economic progress and accordingly formulated four "laws of retardation of progress". One of these "laws" was that "every technical improvement . . . bars the way to further progress" by reducing the number and the range of possibilities still open in a field until finally all possibilities have been exhausted and technical development has ceased.<sup>121</sup> Mombert, while admitting the operation of diminishing returns in agriculture and the limitations on technical progress described by Wolfe, believed that there existed many ways by which these tendencies could be counterbalanced; thus, he anticipated improving living conditions rather than increasing population pressure for some time to come.<sup>122</sup>

## E. Socialist and Marxist writings

51. The socialist writers and reformers focused attention on the class differentiations and the misery of the working class that was attendant upon the growth of capitalism. Even earlier, Thomas More's *Utopia* (1516) contained an egalitarian plea for an ideal state and social organization founded on reason and moral considerations. The early British socialists and particularly, the early French socialists, raised strong objections against the capitalist system; the social reforms they suggested and the theories they held concerning the reorganization of society constituted what is known as "utopian socialism". But it was only with the rise of Marxian "scientific socialism", as opposed to the former, that the working classes acquired a consistent revolutionary theory. Dialectic materialism, Marx's system of philosophy, was in fact a continuation of German philosophical thought, English political economy and French socialistic theory of the nineteenth century.<sup>123</sup> According to the theory of historical materialism, which is an application of dialectic materialism to social change, the history of mankind has been one of continuous class struggle by which less advanced social systems have been replaced by more advanced ones.<sup>124</sup> Just as the establishment of the bourgeoisie replaced the feudal system so, according to this theory, the proletariat, the productive class under capitalism, would replace the bourgeoisie and establish a socialist, exploitation-free society.<sup>125</sup> Marxian political economy, in which the labour theory of value holds a central place,<sup>126</sup> is consistent with dialectic and historical materialism.

52. All the socialist writers have attributed human misery to defects in the capitalist social order, claiming that under the reforms they advocate the productive forces of the people could increase and unemployment and over-population could be prevented. Although these writers were unanimous in rejecting Malthus's theory, their ideas about population differed markedly. The early socialists were concerned with matters related to population, but their views were far from fully developed. Marx and Engels may be credited with formulating a consistent approach to the population problem which most socialists were later to adopt.<sup>127</sup>

For later representative statements that collectivism made for imprudence in matters of population, see Naquet, *Socialisme collectiviste, et socialisme liberal* (1890), chap. 4; Hadley, *Economics* (1896), pp. 45-51; Budge, *Das Malthus'sche Bevölkerungsgesetz* . . . (1912), p. 218. Lloyd questioned this thesis on the ground that since the gain from restricting family size is largely diffused to others, the individual

(Continued on next page)

## 1. EARLY SOCIALISTS

53. The early socialists maintained that, in the reorganized society propounded by them excessive population growth would be prevented by increased production, a better social order and, where possible, by foresight. Such views were evident in the writings of the British Ricardian socialists,<sup>128</sup> who in general tended to reject the Malthusian propositions. Thompson believed that population growth could be brought under control in the co-operative society he envisioned. Bray indicated that, since labour produced all wealth, production would keep pace with population as long as raw materials were available and implied that the numbers of population would be brought under control. Robert Owen, social reformer and socialist writer, established a model industrial community in which the welfare of workers was a major consideration. His social reforms perhaps made a stronger impact than his literary work upon utopian socialism.<sup>129</sup>

54. Socialist views were more vehemently asserted in the works of the early French socialists. Saint-Simon endeavoured to show that poverty could be eliminated under the system of collective industrialism by means of greater productivity. He objected to Malthus's "moral restraint" because it was incompatible with the workers' happiness. While Fourier favoured voluntary control of conception, he believed that changes in living patterns in the "societary state" would bring about population control. Louis Blanc suggested that imprudence was the product, rather than the cause, of misery and that a reorganization of society, by removing misery, would prevent over-population. Proudhon's view was that his type of libertarian socialism would strike a balance between population and production.<sup>130</sup>

55. The German precursors of state socialism, Rodbertus and Lassalle, maintained that the system of private property and free competition depressed wages and encouraged unemployment. Although labour alone could create wealth, workers received only a bare subsistence salary (Lassalle's "iron law of wages"), and population growth merely intensified exploitation of the workers. While the social reforms recommended by Rodbertus and Lassalle differed, they shared a faith in the active role of the workers' state, in contrast to the bourgeois state which left the weak to the mercy of the strong.<sup>131</sup>

56. The Italian socialist Achilla Loria considered population size with respect to capital rather than to

means of subsistence. He maintained that the capitalist system restricted the productive utilization of capital and compelled the masses to work for miserable wages, thereby undermining their continence and exciting them to excessive procreation. He believed that population growth was the cause of economic evolution and of the historical succession of social systems.<sup>132</sup> Nitti felt that each improvement in the economic condition of the working class brought about a lowering of the birth rate, and that the population problem could be solved by a reorganization of society in which the social causes of inequality would be eliminated.<sup>133</sup>

57. According to Valentei, Malinovsky was the first Russian author to disagree with Malthus,<sup>134</sup> as later did Chernishevsky and other "revolutionary democrats"<sup>135</sup> but not on the grounds of social considerations. Milytin was the first representative of utopian socialism in Russia who considered that population was an important factor in the economy, but had a wider social importance, which a population law must take into account. He emphasized the productive capacity of man, whose economic activity, while aimed at the "satisfying of human requirements", should not therefore be viewed as an objective *per se*. He rejected the Malthusian approach and suggested that science should endeavour instead to alleviate human suffering and promote the material well-being of people.<sup>136</sup> Milytin's views concerning population questions were in general optimistic, as were the views of many Russian authors of the nineteenth century.<sup>137</sup>

## 2. MARX AND ENGELS

58. In the broad context of historical materialism, Marx and Engels did not formulate a population theory *per se*, but formulated a set of basic principles which they regarded as governing population and its economic and social correlates. In contrast to Malthus's "abstract" principle of population, Marx held that there could be no natural and universal law of population; population was rather determined by the social and economic conditions prevailing in different societies. He insisted that each specific historic mode of production (which included a variety of social factors)<sup>138</sup> had its own peculiar law of population, historically valid within its limits. In his view, "an abstract law of population exists for plants

and animals only, and only in so far as man has not interfered with them".<sup>139</sup> In *Das Kapital* he outlined the population law "peculiar to the capitalist mode of production", covering both the relative surplus population, which was primarily a socio-economic concept, and the inverse relationship between family size and wage levels, which reflected demographic and social relationships.

59. Marx maintained that Malthus's "over-population" could be ascribed to the capitalist mode of production and to the acquisition by the capitalist class of the surplus labour product rather than to man's supposed biological proclivities. Over-population, which was in fact relative, arose from capital accumulation—a process in which "variable capital", the source of demand for labour, increased less rapidly than did "constant capital", the source of finance of capital assets.<sup>140</sup> In the course of the expansion of the capitalist system, the natural increase in population alone could not satisfy the requirements for readily available labour, but the accumulation of capital, by replacing labour, would generate the surplus population needed for the functioning of the system.<sup>141</sup> Relative surplus population was therefore inherent in the capitalist system; it was a consequence of the accumulation of capital as well as a condition for the continuation of the system. The "industrial reserve army" had to be sufficiently large to hold the pretensions of the workers in check, to keep wages and salaries low, and thus to maintain high rates of surplus value and profit. It was the pivot upon which the law of demand and supply of labour turned.<sup>142</sup>

60. According to Marx, there are three forms of relative surplus population, or unemployment: the floating, the latent and the stagnant. The floating category consists largely of persons displaced by machinery and structural changes within industry. The latent category is made up of that part of the agricultural population which is on the verge of migrating to the cities, mainly as a consequence of the penetration of capital into agriculture. The stagnant category is comprised of workers with highly irregular employment and the lowest levels of living. Different economic and demographic factors specifically contribute to the creation and perpetuation of individual forms of relative surplus population.<sup>143</sup> One is technological progress, which underwent a "complete inversion" in capitalism: "the higher the productiveness of labour, the greater is the pressure of the labourers on the means of

employment, the more precarious therefore becomes their condition of existence".<sup>144</sup>

61. Differences in mortality and fertility, both among social classes and within the working class are, according to Marx, determined by social position, levels of living (a modern term for "the amount of means of subsistence"), work conditions and other social factors.<sup>145</sup> Recalling Smith's observation that poverty encourages "generation", Marx noted that the number of births and deaths, as well as absolute family size, were in inverse proportion to wage levels and, hence, to the means of subsistence available to different categories of workers.<sup>146</sup> He deplored such demographic patterns and pointed out that this was the law of capitalist society which was meaningless to primitive peoples and even to enlightened settlers.<sup>147</sup>

62. While in full agreement with Marx's analysis, Engels made an additional contribution to Marx's approach to population theory. On the one hand, he maintained that the productive power of mankind was unlimited, since productivity in general, and that of land in particular, can increase by the application of capital, labour and science.<sup>148</sup> He thus rejected the law of diminishing returns which he considered implicit in Malthus's principle of population. On the other hand, he stressed that under capitalism surplus population was always bound by surplus capital. This was a contradiction inherent in capitalism which could be overcome only by fundamental "social reorganization". He suggested that even if Malthus were right with respect to the reproductive behaviour of workers, social reorganization was necessary, for only this reorganization and the enlightenment of the masses could make possible "that moral restraint upon the instinct for reproduction which Malthus himself puts forward as the easiest and most effective counter-measure against overpopulation".<sup>149</sup> On another occasion Engels suggested that in the final analysis the decisive factor in history which was dual in nature was "production and reproduction of life itself". On the one hand there was the production of the means of subsistence. On the other hand there was the production of man himself. The higher productivity is and the more developed the production

<sup>144</sup> *Ibid.*, pp. 644-645.

<sup>145</sup> Marx, *Capital* (1867, 1959 ed.), pp. 293-294, 397-398, 465, 641-643.

<sup>146</sup> Under the capitalist system, Marx observes, labour power is so quickly used that the middle-aged worker is apt to be worn out and expectation of life is especially short among the workers in large-scale industry. Under these circumstances successive generations of workers have to succeed one another very rapidly, a need which is satisfied by early marriage and the exploitation of working-class children, which puts a premium upon their production. This law did not, however, apply to other classes of population. See Marx, *Das Kapital* (1867, 1890 ed.), vol. 1, pp. 595-596.

<sup>148</sup> Engels, "Outlines of a critique of political economy" (1844, 1931 ed.). Forty years later, in a letter to Kautsky (1881), he did not consider the question of over-population "to be at all a burning one" at the time when American "mass production and real large-scale agriculture" were in progress; and on the eve of a major change "which must have this consequence among others, that the earth will now be populated". Marx and Engels, *Sochineniia* (1965), vol. 28, p. 108.

<sup>149</sup> Marx and Engels, *Sochineniia* (1955), vol. 2, p. 315.

<sup>139</sup> Marx, *Capital* (1867, 1959 ed.), p. 632.

<sup>140</sup> "With the magnitude of social capital already functioning, and the degree of its increase, with the extension of the scale of production, and the mass of the labourers set in motion, with the development of the productiveness of their labour, with the greater breadth and fullness of all sources of wealth, there is also an extension of the scale on which greater attraction of labourers by capital is accompanied by their greater repulsion . . . The labouring population therefore produces, along with the accumulation of capital produced by it, the means by which itself is made relatively superfluous, is turned into a relative surplus-population; and it does this to an always increasing extent." Marx, *Capital* (1867, 1959 ed.), pp. 641-642.

<sup>141</sup> Marx, *Das Kapital* (1867, 1890 ed.), vol. 1, pp. 594-596.

<sup>142</sup> Engels, *Dialectics of Nature* (1940), pp. 208 ff., 235.

<sup>143</sup> Marx, *Capital* (1867, 1959 ed.), pp. 640-644.

of means of subsistence, the more economic and social factors determine the social order.<sup>150</sup>

63. What would the population situation be in a future socialist society? Marx and Engels were in general much more reserved on this point than their predecessors, but Engels, faced with the discussion on birth control, commented on this in a letter addressed to Kautsky in 1881. He believed that a socialist society would have at its disposal a highly developed productive capacity managed by careful planning. Under such conditions, production would keep pace with population and provide for the population's well-being. He admitted, however, that there was an "abstract possibility" of over-population calling for limits to population growth. Then he suggested that if at some stage communist society found itself obliged to "regulate the production of human beings", just as it would regulate the production of things, it would be "precisely this society . . . which can carry this out without difficulty". He believed that the kind of reduction in fertility rates that had already been spontaneously achieved in France and lower Austria could also be brought about through planning.<sup>151</sup>

64. The economic and social writings of Marx and Engels contain many observations concerning demographic and socio-economic interrelationships. Population is here conceived of in a dual capacity—as a producer and as a consumer—and the term population is used interchangeably for both labour force and population, as it was used by Petty, Smith and others. According to these writings, the sex and age structure of population in early societies was a "physiological foundation" of the division of labour; at a later stage this was replaced by more advanced forms of division of labour in society.<sup>152</sup> The separation of town from country and the acceleration of urbanization attendant upon the concentration of capital, manufacturing and population were both a cause and a consequence of an advanced division of labour.<sup>153</sup> Shifts in the labour force and population from agriculture to non-agricultural industries were an underlying process of urbanization that was stimulated by the growth of manufacturing and by advances in agricultural technology.<sup>154</sup> A certain density of population was a prerequisite for an adequate division of labour, but density was a combined demographic and economic concept, since it depended upon both the geographic distribution of population and transport and communication.<sup>155</sup>

<sup>150</sup> Engels, *Der Ursprung der Familie, des Privateigentums . . .* (1894), p. viii. Plekhanov and Lenin supported Engels's proposition against Weisengrinn and Mikhailovsky. More recently it was challenged by the editors of the Marx-Engels-Lenin Institute but supported by Bojanovski and Pjanić. <sup>155</sup> *Ibid.*, vol. 1, p. 317.

### 3. POST-MARXIAN SOCIALISTS

65. With the bifurcation in the socialist movement the views on population began to differ on both theoretical and political grounds. The "revisionist" stream adopted the neo-Malthusian proposition that birth control tends to improve the living conditions of workers, while the "revolutionary" stream adhered to Marx's and Engels's basic concepts.<sup>156</sup> Social reforms,<sup>157</sup> women's rights issues,<sup>158</sup> progress in demographic statistics and analysis, as well as the demographic change experienced in many countries, brought additional elements into the discussion. But the major factor in the development of a socialist population theory was the emergence of the USSR and a number of socialist states in which Marxian theory became the ideological foundation of the new society.

66. Kautsky, unlike most socialists of his time, initially attached considerable importance to the population question, suggesting among other things the possibility of both Marxian relative over-population and Malthusian absolute over-population.<sup>159</sup> Following Marx more closely in his later writings, he explained relative over-population as a result of the "variable constituent" of capital increasing less rapidly than total capital and the labouring population. From this might ensue an excess of population relative to variable capital with the result that wages would be depressed and profits would rise. This situation would disappear upon the collectivization of the economy.<sup>160</sup> Kautsky believed that under socialism conditions more conducive both to the appropriate regulation of numbers of population and to the increase of production would develop.<sup>161</sup>

67. Bebel's analysis of population questions was primarily related to the status of women under capitalist conditions and in a socialist society, but it also touched upon the more general issue. He believed in the possibility of greatly augmenting the food supply and in changes in reproductive behaviour occurring as a consequence of improved economic conditions. He held that population was likely to increase more slowly in a socialist society than in a bourgeois society, mainly because of the superior position of women under socialism.<sup>162</sup>

68. Lenin, like Marx, objected to the Malthusian principle of population and replied to those Russian authors who misinterpreted Marx's views. He restated

<sup>156</sup> Glass, *Population Policies and Movements in Europe* (1940), p. 83, for instance, after noting that socialist doctrine did not agree with the Malthusian theory of the ever-present pressure of population upon the means of resources, added that "For socialists—as distinct from mere members of the labour party—the remedy for poverty was not primarily a restriction of births but a change in the basis of society".

<sup>157</sup> *Ibid.*, chaps. 2 and 4.

<sup>160</sup> See Kautsky, *The Economic Doctrines of Karl Marx* (1925), part 3, chap. 5.

<sup>161</sup> See Kautsky, *Vermehrung und Entwicklung . . .* (1920), especially chap. 16.

<sup>162</sup> See Bebel, *Die Frau und der Sozialismus* (1894), pp. 441-463.

the view that human reproduction depended directly upon the structure of society, and rejected an abstract population law which bore no relation to "historically different forms of social orders".<sup>163</sup> He suggested that the over-population of agrarian Russia was not the consequence of disparity between human reproduction and means of subsistence, but a result of the penetration of capitalism into agriculture. The specific features of over-population in the non-monetary sector of agriculture were related to the recency of capitalist farming which had to operate in an out-dated feudal setting.<sup>164</sup> He also denied that the law of diminishing returns applied under conditions of technological progress and improved agricultural methods.<sup>165</sup> Lenin as a proponent of socialism saw the development of capitalism in nineteenth century Russia as a transformation of a backward agrarian society into a modern one, founded on the expansion of capitalist production and class differentiation. Significant changes in population accompanied this process, including the growth of industrial population, a decline in the agricultural population, rural-to-urban migration, and the modification of the population's social composition.<sup>166</sup>

69. In contrast to the optimism of the revolutionary labour movement, Lenin said that neo-Malthusianism was a *petit-bourgeois*, pessimist philosophy.<sup>167</sup> It was on these grounds that in 1913 he rejected the "social theory" of neo-Malthusianism, while supporting "unconditioned abolition of all laws prohibiting abortion or dissemination of medical means for preventive measures". He regarded such laws as hypocrisy on the part of the ruling class because they were incapable of curing what he considered wounds inflicted by capitalism. He pointed out that freedom for medical propaganda and the protection of democratic rights of citizens, men and women, are one thing. The social theory of neo-Malthusianism, he noted, is quite another.<sup>168</sup> Lenin's concept of birth control as a human right had a lasting influence both upon socialist writings and health policies affecting fertility.

70. Contemporary socialists have continued to be inspired by Marxian historical materialism and its interpretation of the population problem. Their writings have had to deal with population questions in a complex world in which socialist societies co-existed with capitalist

ones and with a new group of countries that formed *le tiers monde*.

71. In his study of bourgeois population theories, Smulevich on two occasions examined the Marxian law of population peculiar to the capitalist mode of production in the light of modern experience. He asserted that this law operates through the growth of the material part of the productive forces at the expense of and in a manner detrimental to the working class.<sup>169</sup> Analysing the factors affecting birth rates in developed capitalist countries, he argued in particular that the main cause of fertility decline among workers was uncertainty concerning their future and the fear of losing their jobs; this was displayed especially during economic crises when birth rates dropped sharply.<sup>170</sup> Mass unemployment, which had reached its peak during the Great Depression, had been accompanied by the lowest birth rates ever experienced, a phenomenon that was neither biological nor a consequence of improved education, but rather the result of the contradictions of capitalism. Extremely low birth rates and the tendency towards depopulation appeared to be primarily the consequence of relative over-population.<sup>171</sup> This view was reflected in other Soviet writings.<sup>172</sup> Strumilin noted that the decline of fertility in Western countries responded to the social conditions under capitalism and the extinction of the bourgeoisie.<sup>173</sup> Boyarsky suggested that the period of fertility decline in the 1930s, while reducing the labour supply and thus improving the employment situation in the 1950s, could not eliminate unemployment which is inherent in the capitalist system.<sup>174</sup>

72. In Boyarsky's view, socialist reconstruction affected all the vital aspects of society, including population, and the new social ownership of means of production abolished antagonism between them and the main productive force,<sup>175</sup> which was the population. With slight variations in emphasis, Soviet writers maintained that the basic characteristics of the socialist law of population were full employment, the rational utilization of the population's productive capacity, and improvement in the material and cultural components of the level of living of an exploitation-free population.<sup>176</sup> Some authors, however,

maintained that over-population may persist in the initial stages of a socialist society, owing to specific economic and demographic circumstances which are not easy to overcome.<sup>177</sup>

73. With regard to demographic aspects of the population law, Smulevich suggested that socialism made possible a rapid growth of population.<sup>178</sup> He denied that industrialization, general well-being, cultural advancement and the improved social status of individuals would reduce fertility and the natural increase of population in the USSR, as they did in capitalist countries. Moreover, the rate of natural increase in the USSR was several times higher than in the latter.<sup>179</sup> The proposition of rapid population growth seemed to be accepted by many Soviet authors,<sup>180</sup> but was questioned by Strumilin and others. Socialist laws were not inverted capitalist laws, said Strumilin, and both the birth rate and the rate of natural increase had undergone a significant decline, as had the death rate. In the "first phase of communism", relative over-population certainly disappeared while the inverse relation between income and fertility still remained. The "second phase of communism", with further improvements in living conditions, would also reduce differences in fertility.<sup>181</sup>

<sup>177</sup> The possibility of at least temporary over-population under socialism until the achievement of a desirable level of production and development was noted by Lubny Gertsyk, *Chto takoe pere-naselenie* (1923), pp. 46, 56, 89, 100. Agrarian over-population was considered by Cobeljic and Mihajlović as a typical case of relative over-population which can persist in a socialist society. Cobeljic and Mihajlović, "Pitanje agrarne prenaseljenosti u Srbiji" (1953), pp. 3-22. Yin-Chia Ma considered over-abundant population and scarcity of capital an important dilemma in a socialist society. Ma, "New population theory" (1957), pp. 34-41. Litvyakov stated that in the Soviet Union in 1928 agricultural over-population accounted for 8 to 9 million (one-seventh of the agricultural labour force) and urban unemployment for 1.5 million (9 per cent of the non-agricultural labour force). The problem was solved within two to three years. Litvyakov, "Economic and social factors in ensuring full employment (experience of the Soviet Union)" (1967), pp. 308-309.

<sup>178</sup> Smulevich, *Burzhuaznye teorii* . . . (1936), p. 363. In general, Stalin favoured rapid population growth in the USSR. In his writings, however, he made only incidental comments on population as a factor of social progress. He agreed that density and growth of population had an influence upon the development of society, but not a decisive influence. Stalin, *Voprosy leninizma* (1945), pp. 549-550.

<sup>180</sup> Ostrovitianov, ed., *Politicheskaya ekonomiya; uchebnik* (1959), pp. 647-648. Full employment and continuous improvement in the people's well-being under socialism brought about a decrease in mortality and morbidity and a rapid increase in the total population. *Bolshaia sovetskaia entsiklopediia* (1954), vol. 29, p. 175. The encyclopaedia suggests that systematic rapid population growth existed in other socialist countries, as well as in the USSR. See also Valentei, *Problemy narodonaseleniia* (1961), p. 147.

<sup>181</sup> Strumilin, *Problemy ekonomiki truda* (1957), pp. 191-207. Ulanis supported Strumilin's analyses with minor comments and further suggestions concerning the law. Ulanis, "S. G. Strumilin kak demograf" (1962), pp. 341-348. More recently it was pointed out that although almost the same factors contributed to fertility decline in the Soviet Union and in Western countries, under socialist conditions their manifestation differed. Such factors as unemployment, depressions etc. which produce unhealthy effects on fertility, did not exist in the USSR. Podyachikh, ed., *Voprosy narodonaseleniia* . . . (1966), pp. 28-29. Smulevich also noted that in many

74. Chinese socialist writers have rejected the population theory of Hung Tian-Tsi, a Chinese predecessor of Malthus, as they rejected the Malthusian principle of population.<sup>182</sup> In search for a population law pertinent to socialist society, Chang, Mao Gang and Hu have maintained that rational utilization of labour and improvements in living conditions, as well as the elimination of differences between town and country and between manual and intellectual labour, are essential to socialism. As for population growth, they have suggested that mortality will gradually reach a minimum physiological level, while fertility, after reaching a high level, will decline. The change in mortality and fertility should produce a change in population increase, from high and rapid to "stable". A "stable" natural increase in population would mean a rate of increase that is "basically stable", possibly at a low level and with upward and downward variations. The authors have expressed the opinion that in the interest of the people's well-being, as well as the community's, the natural increase in population ought to be stabilized at a relatively low level, a matter to be determined by the policy of Party and of State.<sup>183</sup> Ma's "new population theory" includes relationships between the economy and population and points to the need for birth control in view of the difficulties which rapid agricultural development would encounter.<sup>184</sup> The latter statement evoked a number of comments;<sup>185</sup> nevertheless it was obvious, as Wang suggested, that even with the abolition of private property, the problem of population was not fully solved.<sup>186</sup>

75. Differences in historical circumstances, patterns of transformation of society, and population trends have afforded little common ground for the formulation of a comprehensive population theory pertinent to socialism. While there has been a consensus on questions relevant to population as the only real producer of wealth, differences in opinion concerning the patterns of population growth under socialism still remain. In a general observation, Sweezy suggested that from the standpoint of the optimum population in a planned socialist society, the decline in the rate of population growth "might well be a good thing", for a continuation of high population growth

socialist countries fertility significantly declined. He saw the rationale of population growth under socialism in the following: conscious motherhood; protection of mother and child; harmony between individual and social objectives; adequate demographic and economic policy; and scientific foundation of the policy. Socialist population law was—as a general tendency—the full and rational utilization of human resources and "rational reproduction of population". Smulevich, "K voprosu o zakone narodonaseleniia" (1967), pp. 25-27.

<sup>186</sup> Wang, "Marxist theory of population and the Chinese . . ." (1957).

"must from any standpoint sooner or later be attended with disastrous consequences".<sup>187</sup> Pjanić considered that the experience of the socialist countries was too brief, and that examining any proposition concerning demographic regularities under socialism was rather difficult. Conditions differed among the various socialist countries, as did population trends, so that policies might differ as well.<sup>188</sup> Fajfr also maintained that the study of demographic and social facts and trends was crucial, suggesting that this was even more important than the search for a population law, and that those existing did not correspond to reality but were based on abstract and normative postulates.<sup>189</sup>

76. None of the Marxist writers considered population growth to be a cause of poverty in the colonies; rather they all maintained that this poverty was mainly due to colonial rule and under-development.<sup>190</sup> Under British rule, said Palme Dutt, the rate of India's population growth was markedly less than that of almost any European country.<sup>191</sup> Economic development which, earlier, had facilitated more rapid population growth in Europe was "artificially arrested" in India by the requirements of the metropolises, by the failure of the social and economic organization to develop abundant natural resources, by exports of wealth, and by unfavourable policy measures. The main reason for the extreme poverty lay neither in any natural cause nor in a non-existent "over-population", but in the social and economic conditions existing under imperialist rule.<sup>192</sup> According to Kozlov, colonial expansion contributed to the decline of fertility in some of the former colonies. The breakdown in the primitive social structures coupled with exploitation, low levels of living, and the migration of the male population in search of employment were also among the factors contributing to this decline.<sup>193</sup> Khalatbari suggested that the traditional equilibrium between population and the corresponding pre-capitalist "mode of production" was disturbed without the re-establishment of a new equilibrium at a higher level.<sup>194</sup>

77. The forms of over-population in contemporary developing societies differ just as the causes of over-population and the social and economic settings in which they have operated are different. Khalatbari has

<sup>187</sup> Sweezy, *The Theory of Capitalist Development* ... (1942), p. 225. This proposition never was further elaborated or discussed.

<sup>191</sup> Dutt, *India Today* (1949), pp. 48-49. He said that from 1870 to 1910 only France had a slower rate of growth; from 1872 to 1931 the population increase in India was 30 per cent, and in England and Wales 77 per cent (p. 49). This was of course prior to the initiation of the recent demographic revolution.

<sup>192</sup> *Ibid.*, pp. 50-57.

suggested that a qualitative difference exists between over-population in the advanced capitalist and developing societies. In the latter, over-population is associated with the backwardness of productive power. Over-population has primarily affected the traditional agrarian sector as a result of the rapid growth of the agricultural population and of traditional under-development. He distinguishes three types of over-population: that existing in the village economy, that existing under semi-feudal conditions, and that which is found in the modern sector of the economy. Demographic stabilization and the re-establishment of equilibrium between population and production is a complex process which requires rapid economic growth, the socialist transformation of society and many other related radical changes.<sup>195</sup> Nun has offered a Marxian concept of "marginal masses", a form of relative surplus-population which has come to dominate the Latin American scene. He states that in contrast to the industrial reserve army—a "functional" form of unemployment in the industrialized capitalist system—marginality is either "a-functional" or even "dis-functional" for it is generated by the system but not essential to its functioning.<sup>196</sup> Nun, however, did not work out the demographic relationships with marginality.

78. With the acceleration of population growth in the developing countries in the 1950s, many socialist authors gave increased attention to the population problem in relation to development in general and to family size, employment and food in particular. Since they have placed emphasis on policy aspects, their writings are to be discussed in chapter XVII, which is devoted to the topic of population policies.

## F. Contributions of other disciplines

79. The relationship between population and economic factors, specifically the natural, capital and human resources, are found at the core of most population theories. Nevertheless, other disciplines have contributed significantly to a better understanding of population phenomena and often have formed part of these theories—such as the mathematical assumption of Malthus's geometrical rate of growth of population, or the biological element in his idea of "the passion between the sexes". But these other disciplines have made their own independent contribution to population theory. With the acceleration of scientific progress in the nineteenth century and the development of distinct disciplines, population became a phenomenon which attracted the attention of scientists involved in a variety of disciplines. Progress in the natural and social sciences contributed not only to a better description and analysis of population phenomena, but the conviction which emerged at that time that man and his actions were subject to certain well-defined laws,<sup>197</sup> gave rise to the formulation of population theories in different fields.

# 1. MATHEMATICAL THEORIES: THE "LOGISTIC" LAW AND RELATED THEORIES OF POPULATION GROWTH

80. Attempts to formulate mathematical "laws" of population growth were encouraged by the development of mathematical techniques as well as by the increasing availability of statistics relating to population trends which made it possible to "test" such theories. One of the first to take a mathematical approach to the population problem was Quetelet in 1835. Observing that demographic evolution progresses at an accelerated rate up to a point where it begins to slow down, he asserted that the resistance, or the sum of obstacles opposed to the unlimited growth of population, increases in proportion to the square of the velocity with which population tends to increase. Accordingly, in the absence of a change in underlying conditions, or the "social state", a population tends to grow more and more slowly after a certain point.<sup>198</sup> At Quetelet's request Verhulst submitted this principle to examination and suggested that a symmetrical theoretical curve which he termed the "logistic" was suitable to describe the course of population. Initially Verhulst supposed that the obstacles increase exactly in the same proportion as the superabundant population, but he replaced this supposition with the hypothesis that the obstacles increase in proportion to the ratio of the superabundant population to the total population.<sup>199</sup> However, Verhulst's work was generally forgotten until after 1920, when the logistic curve was independently rediscovered by Pearl and Reed.<sup>200</sup>

81. The logistic "law" and the modified logarithmic equation employed by Pearl and Reed commanded much attention.<sup>201</sup> According to Pearl, growth occurs in cycles and "within the same cycle and in a spacially limited area or universe, growth in the first half of the cycle starts slowly, but the absolute increment per unit of time increases steadily until the mid-point of the cycle is reached. After that point the increment per unit of time

becomes steadily smaller until the end of the cycle."<sup>202</sup> The absolute increase per time period thus shows the form of a symmetrical bell-shaped curve which rises to a peak, at the point where the actual population is one-half the maximum, and then declines again to zero. The total population ( $N$ ) follows an S-shaped curve as it moves from a very low value toward the maximum ( $K$ ). The theory of population growth implicit in the simple logistic curve rests on several assumptions: among them the constant physical environment on which the population depends for its support, the existence of an asymptotic limit ( $K$ ) which represents the maximum population that can exist in the given environment and conditions, and the hypothesis that the population increase is proportional to the absolute population size already attained and the amount still left until the maximum, where the population becomes stationary, is reached.<sup>203</sup>

82. Pearl interpreted the logistic at first as a general "law" without attempting to formulate a logical, theoretical explanation to support it, but he argued that in so far as the logistic appeared to hold for human and non-human populations—including the number of cells in a pumpkin and in a culture of yeast and the number in a population of fruit flies—the theoretical basis for the theory must be found not in social or economic factors and institutions but in biological, physical or chemical natural causes.<sup>204</sup> Nevertheless, even in his earlier work he recognized the influence of other factors. Asserting that a negative correlation existed between fertility and population density, he inferred direct or indirect biological effects of population density on fertility. Among other things, he also noted a negative correlation between birth rates and wealth.<sup>205</sup> In his later works he moved even further away from his earlier determinism.<sup>206</sup>

83. Although the logistic received much attention for a time, its relevance both as a tool for estimating and

<sup>202</sup> Pearl, *The Biology of Population Growth* (1925), p. 22.

<sup>203</sup> Assuming that  $r$  is the maximum rate of increase of the population,

$$\frac{K - N}{K},$$

the fraction by which the actual population ( $N$ ) remains below the maximum ( $K$ ), then the increase of population per unit of time is

$$\frac{dN}{dt} = rN \frac{K - N}{K}.$$

The total population will then be

$$N = \frac{K}{1 + be^{-rt}},$$

when  $t$  is time,  $b$  is a constant.

<sup>204</sup> Pearl, *Studies in Human Biology* (1924), p. 585.

<sup>205</sup> Pearl, *The Biology of Population Growth* (1925), p. 209; Sadler, *The Law of Population* . . . (1830), had already proposed a theory that fertility varies inversely with the density of population. See Coontz, *Population Theories and their Economic Interpretation* (1957), pp. 28-42.

<sup>206</sup> Pearl, *The Natural History of Population* (1939), p. 95. See also Lorimer, "The development of demography" (1959); Robinson, "The development of modern population theory" (1964).

projecting population<sup>207</sup> and as a theory of population growth was widely questioned. One of the objections against the logistic as a theory was that even when there were strong grounds for assuming that population growth would follow an S-shaped curve, it had not been established that because of the inherent nature of the growth process itself, a population must of necessity pursue the path of a logistic.<sup>208</sup> It is, however, on social, cultural and economic grounds that the strongest criticism against the logistic theory has been formulated. The logistic does not effectively take into account changes in those traits which permit a population to exploit its resources effectively nor does it anticipate changes in aspirations and tastes and hence in reproductive behaviour brought about by such factors.<sup>209</sup> Nevertheless, the size of the maximum population, the trends of its growth rates and, in general, the progress of population depend largely upon such social, cultural and economic changes. Critics of the logistic "law" therefore looked upon it primarily as an empirical formula which under certain conditions might describe past or future population trends.<sup>210</sup>

84. Several writers have tried to formulate a general law of population development in a broader context, relying not only upon over-simplified hypotheses and predominantly biological analogies but taking into account various influences, particularly those of an economic nature. An attempt at such a theory was made by Amoroso, who introduced the concept of demographic elasticity in order to represent the relation between the logarithmic derivative of the population and the corresponding logarithmic derivative of an index of economic activity.<sup>211</sup> This concept was used in turn by Vinci to obtain a so-called "generalized logistic curve". According

to Vinci: (a) a demographic elasticity becomes consistently, but as an unknown function of time, smaller as the population becomes greater; and (b) the relative increase of income is a function, also unknown, of time and the relative magnitude of the population.<sup>212</sup> Vianelli applied this theory by investigating how the economic and demographic evolution, as represented by various indices, had influenced one another in the United States and Italy and found that demographic elasticity and the response of output to population growth varied in time and by country.<sup>213</sup>

## 2. BIOLOGICAL THEORIES

85. Apart from the biological interpretation of the logistic law by Pearl and Reed, other writers attempting to elucidate the role of biological factors in the historical process of population have formulated biological theories of population. As noted before in the discussion on the critics of Malthus's theory, Spencer formulated a theory of biological evolution, introducing a self-regulating principle of population growth.<sup>214</sup> He asserted that there existed an antagonism between what he called "individuation" or the power to maintain life, on the one hand, and "genesis" or the power to propagate, on the other hand, and he considered that the former varied directly and the latter inversely with the development of the nervous system. Where the power to maintain life was low, survival of the population required high fertility. When fertility is high population pressure arises and this pressure, in turn, is conducive to improvements in methods of production and intensifies the need for skill, intelligence, self-control and education, thus developing intellectual qualities and raising nervous tension. In consequence man's nervous centres became enlarged, with the result that his "individuation" or power to maintain life increased while his power to reproduce diminished. According to Spencer, his theory, which was general in scope, explained why certain animal species are more prolific than others, why man is the least prolific of the higher animals, and why the upper classes of society—British in the case discussed—have fewer children than the lower classes. In all these cases, the rate of reproduction of the groups whose members are more differentiated and

<sup>207</sup> Frank, "Ecology and demography" (1959), points out that the logistic may provide a satisfactory fit during the active growth path partly because the logistic is so flexible that it will fit both data which show a strong inflection and those which could be approximated by a straight line, but that when the curve approaches the asymptotes, examples that fit reasonably well are rare. On the use and limitations of the logistic for projection, see chap. XV.

<sup>208</sup> For such a theoretical basis it would be necessary to show, for instance, that as population density increases, fertility or mortality has to respond in such a manner as to yield the appropriate rate of slackening of the rate of increase. While, in general, it is thought that a rationale might exist to expect a non-human population to grow in a certain predetermined manner, for a human population, such a possibility has been virtually discarded. Volterra and d'Ancona, *Les associations biologiques au point de vue mathématique* (1935); Rashevsky, *Advances and Applications of Mathematical Biology* (1940); and his *Mathematical Theory of Human Relations* ... (1947).

<sup>209</sup> Adherents to the logistic theory thought that as the result of major changes in such factors a new cycle of logistic growth would be initiated. Wolfe, "Is there a biological law of human population growth?" (1927); Vianelli, "A general dynamic demographic scheme ..." (1936); Hart, "Technological acceleration and the atomic bomb" (1946).

<sup>210</sup> Wolfe, "Is there a biological law of human population growth?" (1927); Knibbs, "The growth of human populations and the laws of their increase" (1925); Dor, "Analyse des phénomènes logistiques ..." (1948); Wilson and Puffer, "Least squares and population growth" (1933); Hogben, *Genetic Principles in Medicine and Social Science* (1931), chap. 7; Douglas, *The Theory of Wages* (1934), chap. 13; Robinson, "The development of modern population theory" (1964).

<sup>211</sup> Amoroso, "L'equazione differenziale del movimento della popolazione" (1929).

<sup>212</sup> Vinci, "La logica della curva logistica" (1929); his "Ancora sulla curva logistica" (1930); and his *Manuale di statistica* ... (1934), vol. 2.

<sup>213</sup> Vianelli, "Evoluzione economica e demografica ..." (1935); and his "A general dynamic demographic scheme ..." (1936). In simplified terms the thinking of these writers can be presented as follows: Assume that the population increases in a small proportion  $x$  and its net income in a small proportion,  $y$ , and further that the increment of income is composed of two parts, one of which ( $y_1$ ) is due to population growth and the other ( $y_2$ ) to other factors such as the advance of technology and the discovery of new resources. Then the demographic elasticity  $e$  is  $x/y$  and the elasticity of productivity of population  $y_1/x$ . For a further generalization of Vianelli's scheme, see Figueroa, "Un modelo dinámico general de desarrollo ..." (1947).

<sup>214</sup> See section D. Spencer's and other theories in this subsection have also been reviewed in chap. IV, section B.

less well adapted is lower than those of the more homogeneous groups.<sup>215</sup>

86. More recently Gini formulated a thesis, the cyclical theory, according to which populations tend to follow an evolution analogous to that of the life course of the individual passing through the successive stages of development, maturity and involution.<sup>216</sup> Gini stressed the role of the fecundity of the population, arguing that the rate of reproduction of a population tended to describe a parabola reflecting not variations in such factors as the amount of subsistence or the environment, but changes in the quality of the "germinal cells". According to his theory, a population cycle is initiated as the result of cross breeding between differentiated groups. Fecundity increases and the rate of growth rises, because fecundity is somewhat hereditary and each generation is largely the product of the relatively more fecund components of the preceding generations. In time, however, the forces making for an increase in fecundity are more than counterbalanced by the forces of "physical exhaustion"—principally a deterioration of germinal cells which is accentuated by the movement of a relatively large fraction of the population into social classes which have characteristically a low fecundity. In consequence, the rate of natural increase starts to decline to a low or even below zero level. Immigration and other movements, by infusing new cross-strains and new blood into the population, may set off another demographic cycle.

87. Another theory concerns the influence which the diet may have on fertility. Some writers in the nineteenth century had already maintained that an inverse relation existed between diet and fertility.<sup>217</sup> More recently de Castro propounded the theory that the fertility of generations diminishes as the diet becomes richer. He obtained his evidence from the association he found between meat consumption and levels of fertility in different countries without, however, firmly establishing a causal relation.<sup>218</sup>

### 3. SOCIOLOGICAL THEORIES

88. A number of late nineteenth and early twentieth century sociological theories considered the relationships between population growth and concentration and the evolution and progress of society. According to some of these, human communities, while they grow in volume and density, experience progress in the form of the development of the division of labour, the extension of personal contacts and the co-ordination of individual activities; the stimulation of initiative and technical innovations

and the creation of other conditions which together make up social progress and the development of civilization.<sup>219</sup>

89. Coste was among those who held that actual social evolution, as distinct from what he termed ideological phenomena, is the result of the growth of population and increases in its density.<sup>220</sup> Durkheim held that the transformation of segmentary societies into organically well-knit communities is brought about by population growth and the subsequent development of the division of labour. The growth and condensation of societies require a more far-reaching division of labour, which can be attained more rapidly the faster the number of individuals increases.<sup>221</sup> More recently, Dupréel and his school stressed the importance of population growth for technical and social progress and for the consequent raising of the cultural and material levels of living. According to this thesis, population growth produces effects such as the augmentation of social mobility; increased frequency in personal contacts and in consequence, in social and intellectual stimuli; changes in values including greater emphasis on the future; a more optimistic and enterprising climate of expectation, and intensified technological progress and innovation. These and other effects, it is argued, more than offset any adverse initial implications of population growth. In contrast, a low rate of population growth or a population decline would have the opposite effects.<sup>222</sup>

90. A number of writers have speculated about the interrelations between the decline in fertility in the economically more developed countries and social conditions. Noting that this phenomenon spread simultaneously with changes in social environment, they enumerated such factors as the diversification of man's activities, his increasing individuality, his growing concern with well-being and the more widespread employment of women. Also discussed as active in shaping attitudes in favour of reducing the size of families were factors associated with the urbanization process and the growing spirit of rationalization.<sup>223</sup>

91. A theory on this basis was developed by Dumont, who formulated the principle of "social capillarity". He, like a number of other writers before him, believed that the weakening of the desire to procreate was caused by the progress of civilization and attributed the reduction in family size to the individual's ambitions to improve his position in society. Using a comparison, he argued

<sup>215</sup> Spencer, *The Principles of Biology* (1867), vol. 2, pp. 406-410, 480-506; and his *A New Theory of Population, Deduced . . .* (1852). See also Coontz, *Population Theories and the Economic Interpretation* (1957), pp. 53-56.

that just as water can rise only under the force of capillarity in thin tubes, an individual can rise in the social scale only by having fewer children. The development of individualism and the desire for personal improvement and that of the children in advanced societies created, in his view, a state of mind conducive to declining fertility.<sup>224</sup> While agreeing that changes in social environment due to the progress of civilization were at the basis of the fertility decline, other writers attributed the latter more to the diversion of energies from procreation to the intellectual and physical activities imposed by the way of life. The declining birth rate then was supposed to reflect the pressure of those needs.<sup>225</sup>

## G. Focus on population

92. Towards the end of the nineteenth century population became to an increasing extent a subject of separate study. This trend, exemplified primarily by the shift away from population theory and toward empirical demographic research, can also be found in those theoretical approaches which emerged at that time: optimum population theory and theoretical or pure demography. Although closely related they do not fall strictly within the field of population theory. Optimum theory, inquiring as it does into the most favourable dimensions of population, fundamentally poses a problem of policy. Theoretical demography, in studying the quantitative relations among demographic phenomena, makes abstractions from the interrelationships between demographic variables and other phenomena. However, at the same time these approaches have contributed to a clarification of many issues involved in population theory and, in this manner, constituted important elements in the development of population theory.

### 1. OPTIMUM POPULATION THEORY

93. At the basis of the theory of optimum population is the relationship between population and resources. The ingredients of such a theory can already be found in the works of economists of the classical school who discussed the effects of population size and growth on the specialization and division of labour on the one hand, and on the onset of diminishing returns on the other.<sup>226</sup> The basic elements of the optimum population theory can be found in the writings of Sidgwick. He observed

<sup>224</sup> Dumont, *Dépopulation et civilisation* ... (1890), pp. 106 ff.; and his *Natalité et démocratie* ... (1898), pp. 163-166, 190-191, 212-216; Coontz, *Population Theories and the Economic Interpretation* (1957), pp. 57-61.

<sup>225</sup> Hankins, "Does advancing civilization involve a decline in natural fertility?" (1930). See also Spengler, *France Faces Depopulation* (1938); and Fisher, *The Social Selection of Human Fertility* (1932).

<sup>226</sup> See, for instance, West, *Essay on the Application of Capital to Land* (1815); Mill, *Principles of Political Economy with Some of their Applications to Social Philosophy* (1848). Spengler, "French population theory since 1800" (1936), considered Sismondi, Gide and Effertz also as precursors of the optimum population theory. Sauvy, *Théorie générale de la population, vol. 1* ... (1963), p. 50, mentioned in addition More, Botero, Machiavelli, Cantillon, Necker, Rousseau, Quesnay, Adam Smith, Malthus and others as fore-runners of the theory.

that as a result of the aforementioned factors, the productivity of labour tended to diminish as the proportion of labourers to land increased after a certain degree of density had been reached; that there was a point of maximum return per head, and that this depended on the state of arts, the capital accumulated and technical progress.<sup>227</sup> While Sidgwick thus laid the foundation for a dynamic theory of optimum population, Cannan is usually thought to have defined what later came to be called the concept of "optimum population" in a static sense. He affirmed that "at any given time the population which can exist on a given extent of land consistent with the greatest productiveness of industry possible at that time is definite". At the same time, however, he held that "the existence of over-population or under-population is not susceptible of exact demonstration".<sup>228</sup>

94. Different criteria have been used to define optimum population. The concept has been variously interpreted as to mean that size of the population which results in the highest *per capita* income,<sup>229</sup> the highest productivity as measured in different manners,<sup>230</sup> or the highest level of other less well-defined economic indicators such as economic welfare, level of living, real income and in some cases, employment.<sup>231</sup> Other writers, some of whom considered the concept of economic optimum as excessively restrictive,<sup>232</sup> have broadened optimum population to refer to other non-economic factors, including the

<sup>227</sup> Sidgwick, *The Principles of Political Economy* (1883), pp. 150-155.

<sup>228</sup> Cannan, *Elementary Political Economy* (1888), part 1, sect. 7. For the contributions to the development of optimum population theory of different writers see Robbins, "The optimum theory of population" (1927); Wolfe, "The population problem since the World War: a survey of literature and research" (1928); Cohn, *Die Theorie des Bevölkerungsoptimums* (1934), pp. 15-22, 81-83; Whittaker, *A History of Economic Ideas* (1946), pp. 347-350; Spengler, "Marshall on the population question, part 1" (1955).

<sup>229</sup> Robbins, "The optimum theory of population" (1927); Hicks, *The Social Framework* ... (1950), p. 198; Wolfe, "The optimum size of population" (1926), favoured the use of *per capita* value of consumers' goods; Penrose, *Population Theories and their Application* ... (1934), p. 84, included the qualification that income should be spent so that it resulted in the greatest welfare.

<sup>230</sup> Cannan, *Wealth* ... (1914), pp. 57-58; Wolfe, "The theory of optimum population" (1936); Gottlieb, "The theory of optimum population for a closed economy" (1945). In connexion with measuring optimum population with respect to income or productivity the point was raised, that optimum population was not only a question of the size but also of the structure of population. See Mombert, "L'optimum de population" (1935); Cohn, *Die Theorie des Bevölkerungsoptimums* ... (1934), p. 143; Ferenczi, *The Synthetic Optimum of Population* ... (1938); Plummer, "The theory of population: some questions of quantity and quality" (1932). Gottlieb, "The theory of optimum population for a closed economy" (1945), dismissed, however, the importance of the age distribution in this respect.

<sup>231</sup> Fairchild, *People: the Quantity and Quality of Population* (1934), pp. 64-70; and his "Optimum population" (1927). For a critical review of the use of such general concepts as "standards of living" or "welfare" in this connexion, see Cohn, *Die Theorie des Bevölkerungsoptimums* ... (1934), pp. 69-70; Rao, "The optimum population" (1939); Wolfe, "On the criterion of an optimum population" (1937). Carr-Saunders, *World Population* (1937), p. 330, thought, however, that for practical purposes "maximum economic welfare" could be taken as equivalent to real income per head.

<sup>232</sup> Thompson, *Population Problems* (1935), pp. 429-432; Penrose, *Population Theories and their Application* ... (1934), p. 73; Reuter, *Population Problems* (1937), pp. 279-280.

total of well-being, health, longevity, ideal family size, the conservation of natural resources, power, defence, and other spiritual, cultural and aesthetic factors.<sup>233</sup> Nevertheless, most of the literature on optimum population has been concerned with the economic optimum.

95. Criticism of optimum population has been strong and many writers have challenged the practical applicability as well as the formal validity of the concept as originally formulated.<sup>234</sup> As far as the former is concerned, while many writers agree that it may be possible to give some meaning to the concept of "under-population" or "over-population", the majority among them expressed doubt whether optimum population, in the sense of an "optimum point" can be determined. A number of writers have, therefore, referred to an optimum zone, area, plateau or range, with those taking a critical view of the theory asserting that the concept of optimum population thus becomes indeterminate.<sup>235</sup>

96. More fundamental are those objections against the optimum theory which stress its essentially static nature. Many writers have pointed out that formally the optimum theory assumes a *ceteris paribus* condition for all other factors—technology, resources, social structure and external trade to name a few.<sup>236</sup> Such an assumption, it is argued, is highly unrealistic; in the time it would inevitably take the population to adjust to the optimum determined under the assumption of *ceteris paribus*, the real optimum itself would have shifted, since the other factors in fact, are constantly changing.<sup>237</sup> Another argument in this connexion, already advanced by Cannan, stresses the fact that the population at a given time is

part of a process of continuing demographic change and that it cannot be dissociated from the population which preceded it nor from the population which will follow. Asserting that there is no reason for isolating the present population in preference to others, Cannan held that optimum population should be treated in terms of the "right movement" of population increase or decline rather than with reference to a particular point of time.<sup>238</sup> In view of these criticisms the problem of optimum population has been described not so much as that of adjusting a variable population to a given technology and resources but as that of harmonizing population changes with those that take place in the other factors involved.<sup>239</sup> Such a formulation, although significantly complicating the practical task of ascertaining the optimum population,<sup>240</sup> introduces a dynamic element. It does not, in the view of many, however, resolve the problem that optimum theory also assumes the independence of technology, capital resources and other relevant factors from population, while in reality there exist complex interrelationships between population and these other factors.<sup>241</sup> It follows that unless these interrelations are known<sup>242</sup> or can be ignored,<sup>243</sup> it becomes impossible to determine the optimum population.

97. While optimum theory received most attention during the 1920s and 1930s, a more recent contribution to it was made by Sauvy. Contrary to many of the earlier writers, he considered the concept of optimum population—which he defined as that population which best assures the realization of a pre-determined objective—not so much as an absolute theoretical concept but as a convenient tool. Recognizing that the concept was essentially static and implied the questionable assumption that all other things except population size remain the same, he nevertheless held that the concept of optimum greatly facilitates the analysis of the influence of population on other factors.<sup>244</sup> After analyzing the economic and power optimum in an over-all, static manner, he dealt subsequently with the influence of structural aspects—such as the distribution of population among workers and non-workers, among different economic activities and among different social classes in terms of his "theory of domination". He then considered the effects of dynamic factors—

<sup>233</sup> Mukerji, "The optimum in recent population theories" (1937); Fraser, "On the concept of an optimum in population theory" (1934); Ferenczi, *The Synthetic Optimum of Population* . . . (1938); Dupréel, "L'optimum de population et ses critères" (1928); Mukerji, *The Political Economy of Population* (1943), chap. 8; Gini, "Considerations on the optimum density of a population" (1929); Sauvy, *Théorie générale de la population*, vol. 1 . . . (1952, 1963 ed.), pp. 51-52, 67-79.

<sup>234</sup> Whelpton, *Needed Population Research* (1938), p. 157; Sarkar, *The Sociology of Population* . . . (1936), p. 34; Myrdal, *Nation and Family* . . . (1941), p. 86; Mombert, *Bevölkerungslehre* (1929), p. 242; Sorokin, *Contemporary Sociological Theories* . . . (1928, 1964 ed.), p. 402; Myrdal, *Population: a Problem for Democracy* (1940, 1962 ed.), p. 26; Reuter, *Population Problems* (1937), p. 278; Osborn, "Optimum rates of population growth" (1958); Robinson, "The development of modern population theory" (1964).

<sup>235</sup> Cohn, *Die Theorie des Bevölkerungsoptimums* . . . (1934), p. 112, cites Gini as speaking of an optimum zone; Penrose, *Population Theories and their Application* . . . (1934), p. 57, uses the expression "plateau"; Fairchild, *People: the Quantity and Quality of Population* (1939), pp. 87-88, suggests the use of optimum "area"; Hicks, *The Social Framework* . . . (1942), p. 199, uses the word "range"; Gottlieb, "The theory of optimum population for a closed economy" (1945), adds that the productivity (or income) curve is not necessarily continuous, but may exhibit irregularities in inflection and even reverses because of the discontinuities in the process of economic growth. See also Cohn, *Die Theorie des Bevölkerungsoptimums* . . . (1934), pp. 112 ff.; Myrdal, *Population: a Problem for Democracy* (1940; 1962 ed.), p. 142.

<sup>236</sup> In general the theory of optimum population deals with an isolated state or closed economy. See, for instance, Cohn, *Die Theorie des Bevölkerungsoptimums* . . . (1934), p. 124. However, Gottlieb, "Optimum population, foreign trade and world economy" (1949), discussed the theory in the setting of an open economy.

<sup>237</sup> Myrdal, *Population: a Problem for Democracy* (1940, 1962 ed.), p. 143; Hicks, *The Social Framework* . . . (1942), pp. 199-200.

<sup>239</sup> Rao, "The optimum population" (1939); Cohn, *Die Theorie des Bevölkerungsoptimums* . . . (1934), p. 21.

<sup>240</sup> Cannan, *A Review of Economic Theory* (1929, 1964 ed.), p. 83; Myrdal, *Population: a Problem for Democracy* (1940, 1962 ed.), p. 143.

<sup>241</sup> Cannan, *A Review of Economic Theory* (1929, 1964 ed.), p. 82; Fairchild, "Optimum population" (1927); Cohn, *Die Theorie des Bevölkerungsoptimums* . . . (1934), p. 125; Mombert, "L'optimum de population" (1935).

<sup>242</sup> For a discussion as to the state of knowledge of the effect of demographic factors on such variables as capital formation, employment and productivity see chap. XIII.

<sup>243</sup> Gottlieb, "The theory of optimum population for a closed economy" (1945), thought that the assumption of the independence of the "other variables" postulated by optimum theory constitutes a reasonable working hypothesis.

<sup>244</sup> Sauvy, *Théorie générale de la population*, vol. 1 . . . (1952, 1963 ed.), pp. 50-54. See also his *Richesse et population* (1944).

such as technological progress and changes in the structure of the economy and employment—on the optimum population. Finally, he discussed the policies for attaining optimum population, their effectiveness and costs.<sup>245</sup>

## 2. THEORETICAL DEMOGRAPHY

98. Theoretical demography, also often referred to as formal or pure demography, is concerned with the immediate factors which influence the size and change of population, determining the influence which each of these factors exert as well as the mechanism they form together. Pure demography, in studying the immediate causes, it has been asserted, logically constitutes the first stage in demographic theory. Once those causes have been established, the less direct determinants from which the direct ones depend should be studied.<sup>246</sup> In other words, theoretical demography is concerned exclusively with demographic phenomena and the necessary mathematical and quantitative relations among them and does not consider social, economic or other factors.<sup>247</sup>

99. Theoretical demography may be said to have come into existence with the development of the life table interpreted as providing the proportional distribution by ages of a hypothetical population with constant age specific mortality rates and a given and equal number of births and deaths.<sup>248</sup> In the eighteenth century, Euler, assuming a hypothetical population with a constant schedule of age-specific mortality rates and a constant rate of increase, showed that such a population would have a stable age distribution and that its other demographic characteristics could be completely determined.<sup>249</sup> The basis for the calculation of reproduction rates and especially the net reproduction rate as a measure of the replacement of one generation by the succeeding one, was laid by Lexis<sup>250</sup> in the latter part of the nineteenth century. It was developed by Böckh<sup>251</sup> and later, by others, including Kuczynski<sup>252</sup> and Dublin and Lotka.<sup>253</sup>

100. A general and complete theory of the interrelations of the basic demographic processes, including the determination of the age structure and other functions of the population, was developed by Lotka.<sup>254</sup> The study

of quantitative demography or population analysis, according to Lotka, can be undertaken from two points of view or by two methods: the empirical method and the rational or formal method. The rational method, he notes, is possible because of the necessary relations imposed by biological laws or the laws of logic between various demographic characteristics, and is indispensable in order to obtain a satisfactory understanding of population phenomena. The internal factors, such as birth rates, death rates and rates of natural increase of a population of living beings are thus connected by a variety of interrelations. While his approach was essentially biological, Lotka recognized that the study of human population necessitates the consideration of a number of relationships which do not exist or are subordinate in other species, but he noted that fundamentally these were special aspects of the general phenomenon of biological reproduction.<sup>255</sup>

101. In his analytical theory Lotka began by discussing the relationships in a closed population between the basic demographic variables, such as population growth, births, deaths and their respective rates, age-specific survival ratios and the age distribution. In the course of his analysis he formulated certain assumptions as to some of these factors and on this basis distinguished between various population types. A Malthusian population was defined as one in which mortality and age structure are constant. Taking fertility into account, he distinguished a population, commonly referred to as stable, in which both age-specific fertility and mortality schedules are constant.<sup>256</sup> On the basis of these assumptions he analysed the relationships between the different demographic phenomena and derived certain properties of the populations concerned, demonstrating that under these conditions the crude birth and death rates and the rates of natural increase,<sup>257</sup> among others, would be constant.

102. Apart from its usefulness for practical applications, Lotka's work constituted a significant contribution to a better understanding of the demographic processes, the interrelations between demographic factors and their respective roles. Nevertheless, more recent work on this subject has shown various limitations in his analysis. In particular a number of writers have noted that in considering only individuals of one sex, Lotka evaded or

<sup>245</sup> Sauvy, *Théorie générale de la population*, vol. 1 ... (1952, 1963 ed.).

<sup>246</sup> Landry, *Traité de démographie* (1949), pp. 506-507.

<sup>247</sup> Lotka, "Population analysis" (1936, 1956 ed.); Landry, *Traité de démographie* (1949), p. 487; United Nations, *Multilingual Demographic Dictionary* (1958), p. 3; Hauser and Duncan, "Demography as a body of knowledge" (1959); Lorimer, "The development of demography" (1959).

<sup>256</sup> The term "stable populations" may be interpreted in two ways: either as a sub-set of Malthusian populations with constant fertility in addition to constant mortality or as the limiting state of a process of demographic evolution in which mortality and fertility remain unchanged. See United Nations, *Le concept de population stable* ... (1966), pp. 2-3.

<sup>257</sup> Lotka called a population with constant mortality and age distribution Malthusian because the rate of increase of such a population would be geometrical, and Malthus assumed that population would tend to increase geometrically.

ignored difficulties in relationships between male and female reproduction rates in stable populations.<sup>258</sup>

103. A more general framework was used by Winkler, who introduced the term "demometrie"—defined as the precise measurement of population development by mathematical means. Demometrie may be based on either real or theoretical populations. According to Winkler, it involves the refining and further development of available statistics, the improvement of techniques for data collection and analysis, the graphic representation of data and the construction of demographic models. Demographic models may be empirical, that is based on observations of real populations, or constructed—built up from certain assumptions. Winkler classified these models according to content, scope, assumptions and whether they were static or dynamic, functional or stochastic, complete or partial, and then analysed them in these different forms and types.<sup>259</sup>

## H. Recent developments

104. Over the last few decades the evolution of population theory has been dominated to a great extent by two trends. In the first place, progress in demographic analysis, and particularly in the study of fertility and mortality, has confirmed the necessity of formulating population theories not in terms of over-all population growth, but in terms of its main components—fertility and mortality. Secondly, this period has witnessed an increasing preoccupation with the problems of economic development in the economically less advanced countries and the repercussions of high rates of population growth and characteristics associated with it on the process of development. These circumstances have been responsible for an increasing amount of literature dealing with, on the one hand, the theory of demographic transition, which inquires into the simultaneous behaviour of fertility and mortality through time and, on the other hand, with the increasing number of models and theories of economic development which incorporate theories of population as one of their basic ingredients. Nonetheless, despite the better insight and the clearer understanding they have provided, none of the approaches has as yet produced a completely acceptable or accepted theory of population.

### 1. THE THEORY OF DEMOGRAPHIC TRANSITION

105. Contrary to most other theories of population, the theory of demographic transition derives from actual historical experience. On studying the demographic evolution of the countries in the Western sphere of civilization, a number of writers inferred that populations historically pass through different more or less well-defined stages. Developed as an attempt to formulate a

<sup>258</sup> Vincent, "De la mesure du taux intrinsèque ..." (1946); Hajnal, "Aspects of recent trends in marriage in England and Wales" (1947); Karmel, "The relations between male and female reproduction rates" (1947); and his "The relations between male and female nuptiality in a stable population" (1948).

<sup>259</sup> Winkler, *Demometrie* (1969). See also his *Typenlehre der Demographie* ... (1952) and his "Types and models in demography" (1963).

generalized explanation of the process of mortality and fertility decline in these countries, the transition theory was elaborated and received a much broader interpretation in more recent decades, when it was thought to be applicable also to the less developed countries still in the early stages of demographic change. In effect, transition theory has come to be increasingly considered as a theory which might anticipate the future demographic trends in countries presently in the early phases of transition. These are characterized by high population growth as a result of rapidly decreasing levels of mortality and high but more or less stable fertility levels.

106. Landry was probably the first to attempt a description of the demographic stages. In a study published in 1909 he identified three main stages, or "régimes", of population.<sup>260</sup> He held that in studying the influence of economic factors on population the crucial factor is productivity. In answering the question as to how variations in productivity affect population, he said three economic régimes must be distinguished: the primitive, the intermediate and the modern. The primitive régime is characteristic of all living beings other than man, although it has been characteristic of man in the past and can still be found. Fertility, without necessarily attaining its physiological maximum (because of, for instance, customs of marriage), is not subject to any restrictions originating in economic factors—such as the economic consequences of having children. The economic factor does influence mortality through which it regulates population growth. Population will tend to the maximum limit determined by the means of existence and will reach that maximum when mortality, due to the depressing effect of a growing population on levels of living, will increase and reach and fluctuate around the level of natality. The "intermediate régime" is not well defined. Under it, according to Landry, economic factors will affect fertility through nuptiality. In order to maintain certain levels of living which have been acquired and become customary, marriage will be postponed or foregone. Population growth will be affected and population will tend towards a level below the maximum. In the "modern régime" caused by the "demographic revolution", economic factors no longer play the role they had in earlier stages. The decline in birth rates is general under this régime and the result of conscious family limitation, indicating also a change in the aspirations of man concerning his conditions. Although the increase in levels of living itself may have contributed to shaping such attitudes and certain interrelations between population and economy remain, there is no more a "law of population" which tends to determine an equilibrium. On the other hand, the decrease of fertility is not necessarily indefinite or inevitable.<sup>261</sup>

107. Thompson, in an attempt to generalize the demographic experience of Europe into a theoretical framework which could apply to other areas as well, grouped the nations of the world into three groups according to the level of their birth and death rates. Starting with

<sup>260</sup> Landry, "Les trois théories principales de la population" (1909, 1934 ed.); and his *La révolution démographique* ... (1934).

<sup>261</sup> Landry, *Traité de démographie* (1949), pp. 535-547.

the countries which were at a demographically more advanced stage, he distinguished:

(a) Countries with very rapidly declining birth and death rates, with the former declining more rapidly so that the growth rate is also declining;

(b) Countries with declining birth rates and death rates for certain classes, but with death rates declining as rapidly or more rapidly than the birth rate, producing a stable or even increasing growth rate, and

(c) Countries where both birth and death rates are less controlled, but where there is evidence that the death rates are coming under control faster than birth rates, producing the likelihood of a very rapid increase in numbers in the future.<sup>262</sup> Blacker identified five stages of demographic evolution:

(a) The high, stationary stage characterized by high birth rates and death rates;

(b) The early expanding stage with high birth rates and high but decreasing mortality rates;

(c) The late expanding stage with falling birth rates but more rapidly decreasing mortality;

(d) The low stationary stage, with low birth rates balanced by equally low mortality; and

(e) The declining stage with low mortality, lower natality and deaths exceeding births.<sup>263</sup>

108. Notestein stated that the growth of Europe in the modern era involved initially declining mortality produced by the process of modernization as a whole, including rising levels of living and new controls over disease. Fertility responded more slowly to modernization, but ultimately began a decline through the widespread use of contraception under the impact of such factors as growing individualism and rising levels of aspiration developed in urban industrial living. Noting that the more rapid response of mortality than of fertility to the forces of modernization is probably inevitable, he distinguished three demographic types or stages of demographic evolution:

(a) Populations with incipient decline or "transition completed" (United States, Europe, Australia), characterized by a fertility rate declining to or even below the replacement level;

(b) A transitional type of population (Soviet Union, Japan, some countries in Latin America) with a rate of growth which is still relatively rapid, but where a decline in the birth rate is well established; and

(c) Populations with high growth potentials or transitional growth not yet begun (most of the countries in Africa, Asia and Latin America), where fertility remains high with no tendency to decline and where the high, but declining death rate is the main growth factor.

<sup>262</sup> Thompson, "Population" (1929); his *Population and Peace in the Pacific* (1946), chap. 2; and his *Plenty of People* (1948), chap. 6.

<sup>263</sup> Blacker, "Stages in population growth" (1947). Davis, "Population and resources" (1950), argued that another stage should be added to those distinguished by Blacker and Thompson: relatively low and stable natality remaining above mortality and permitting a significant rate of increase.

He was of the opinion that the study of the beginnings of economic development and demographic transition in certain non-European countries suggested that the principles drawn from the European demographic transition would be widely applicable in the world.<sup>264</sup>

109. The process of demographic transition in the course of economic development as based on the experience of the presently industrialized countries has been summarized by Coale and Hoover. The agrarian low-income economy, they stated, is characterized by high birth and death rates, the former being relatively stable and the latter fluctuating in response to varying fortunes. Then, as the economy progresses to become more interdependent, specialized and market-dominated, the average death rate begins a continuing decline under the impact of better organization and improved medical knowledge and care. Somewhat later the birth rate begins to fall. The birth and death rates pursue a more or less parallel downward course with the decline of the birth rate lagging behind. Finally, as further reductions in the death rate become harder to obtain, the birth rate again approaches equality with the death rate and a more gradual rate of growth is re-established, with, however, low risks of mortality and small families as the typical pattern. Mortality rates then become relatively stable from year to year and birth rates respond to voluntary decisions rather than deeply embedded customs and may fluctuate from year to year.<sup>265</sup>

110. While the idea of a demographic transition has been widely adopted and is frequently used as a generalized description of the evolutionary process, a number of writers have emphasized its limitations as a theory. It has been argued that since the transition theory is linked to the experience of Western countries, whose historical demographic trends were by themselves far from uniform,<sup>266</sup> it is unlikely that it provides more than vague suggestions about factors which may determine growth in other countries.<sup>267</sup> Cowgill, for instance, distinguishes different types of cycles of population growth determined by different patterns of behaviour of birth and death rates which may diverge from the sequence assumed in the transition theory.<sup>268</sup> Billig, dealing separately with the stages of demographic evolution in the capitalist and socialist countries, maintains that the

<sup>265</sup> Coale and Hoover, *Population Growth and Economic Development* . . . (1958), pp. 10-13.

<sup>266</sup> On the different forms and "turning points" in demographic transition, see Pavlik, "Nastin populacniho vyvojestveta" (1964); and his "Les problèmes de la révolution démographique" (1967). Van de Walle and Knodel, "Demographic transition and fertility decline" (1967), analysing data for European countries, concluded that a simple statement of transition theory and the threshold hypothesis was incapable of describing the actual experience of Europe satisfactorily.

<sup>267</sup> Van Nort and Karon, "Demographic transition re-examined" (1955); Hauser and Duncan, "Demography as a body of knowledge" (1959).

<sup>268</sup> Cowgill, "The theory of population growth cycles" (1949). See also Mackensen, "Theoretical considerations regarding differential transition" (1967).

process of demographic evolution in the socialist countries should be studied on the basis of the experiences of those countries, particularly that of the Soviet Union. Reviewing the stages of development of the Soviet population, he explains them as a result of social transformations and the progress of industrialization.<sup>269</sup> Valentei also questions whether industrialization has the same influence in socialist countries as in others and, like some non-Marxist writers, also challenges the contention that the experience of western capitalist countries is valid—as is claimed—for the economically less developed countries of Asia and Africa.<sup>270</sup> With respect to countries undergoing transitional growth, a number of writers have pointed out that at least the tempo of change in them differs considerably from that observed in countries which completed the transition earlier, especially as far as the rapidity of the decline in mortality is concerned and also in regard to the fact that in some western countries fertility fell before any major decline in mortality occurred.<sup>271</sup>

111. Another and more fundamental criticism of the transition theory is that as a theory it is unsatisfactory. Transition theory, it is argued, is not a theory, but a description of historical events that have occurred in the developed countries with some regularity. It has only suggested certain major complexes of factors which presumably influence the components of population growth, and thus raises serious questions as to its explanatory and predictive value. As it is, the theory is an interpretation of turning points in demographic evolution rather than a system of logically consistent and explicit relationships that provide a basis for pertinent deductions and predictions of future developments.<sup>272</sup> These limitations of the theory, however, were not overlooked by those propounding it. Notestein noted, for instance, that not all the components of the process of modernization could be listed and no precise weights could be assigned to factors which could be isolated. On the other hand, he held that the theory of the broad process of population change seems to have been sufficiently tested to prove its general validity, but that what was needed was knowledge at lower levels of generality.<sup>273</sup> Other writers also have contended that the theory of demographic transition provides a satisfactory framework and means for wider empirical generalizations.<sup>274</sup> For such a development

the explanation of fertility trends and especially of the onset of fertility decline appears to be the crucial factor.<sup>275</sup>

## 2. POPULATION AND ECONOMIC DEVELOPMENT

112. After the relative neglect of population in the writings of the neo-classical school of economics, the interest of economists in the population factor revived with the emergence and ensuing discussion of the stagnation theory. This theory stressed the potentially negative effects of declining population growth on economic progress in the economically advanced countries.<sup>276</sup> The main impetus for the increased interest in population on the part of economists in the recent period is, however, to be found in the predominant place the problems of economic development of the less advanced countries occupy in contemporary economic analysis. Two factors are responsible for this increased interest. In addition to the development problems emanating from existing imbalances between population and resources, there are others created by the unprecedented high rates of population growth characteristic of most developing countries. Although there is more or less a general agreement that economic development is intertwined with population problems and that prevailing patterns of population growth in the developing countries have important economic repercussions, there have been relatively few attempts to introduce population as an integral factor into the study of economic growth. Even where population has entered into development theory and models, it has done so mostly in the form of an independent or exogenous variable and there are only a few cases where a systematic attempt has been made to integrate economic and population theory. In addition, in the instances where such attempts were made, views on the role of population continued to be heavily influenced by Malthusian theory.<sup>277</sup>

113. The relevance of Malthusian theory for modern economic and population theory was discussed by Peacock on the basis of a "model" containing the fundamental Malthusian assumptions and hypotheses. The latter, according to the author, were:

(a) Population is an increasing function of the average output per head of population;

(b) The supply of labour is an increasing function of the level of population; and

(c) The application of successive increments of labour to the fixed supply of capital and land will, after a certain point, result in a declining product per head of population. From these hypotheses, and an assumption concerning the subsistence level of living, it would follow that population always tends to the level which will be just supported at a minimum subsistence. There is, however, Peacock asserts, no reason why these hypotheses and assumptions

<sup>275</sup> Concepción and Murphy, "Wanted: a theory of the demographic transition" (1967), see an evolution in this direction, particularly in the recent attempts to formulate new theories of fertility decline. See also chap. IV of this study.

<sup>276</sup> Several aspects of the stagnation thesis are discussed in chap. XIII.

<sup>277</sup> Levine, "Economic science and population theory" (1965).

should be accepted. He particularly questions the assumption that population is a function of output and that the latter is in turn indirectly, as implied in the last two hypotheses, a function of the size of the population. From the view point of economic theory, Peacock states, the important question is to what extent production depends on population and the supply of labour. The crucial issue for population theory, however, is whether population can be considered a function of production or more specifically a function of average income per head. As the historical experience of western countries suggests, population, instead of being positively associated with level of income—as assumed in Malthusian theory—may in fact be a decreasing function of income. Nevertheless, even though the relation between population and levels of living as postulated in Malthusian theory is highly questionable, this does not mean that there is no relation between population and material conditions. Actually, the spread of preventive checks, which disproved Malthus's assertion that the biological principle of "the passion between the sexes" was the determinant of reproduction, gave added significance to economic factors. With the introduction of these checks the question of choice in the procreation of children becomes important. The motives for having children are reflected in economic choices, the cost of having children being measured in terms of the alternatives forgone.<sup>278</sup>

114. Coontz attempted to formulate a theory of population growth consistent with the thesis of the classical school that the demand for labour governs its supply. He assumed mortality to be directly related to fertility, while taking the generally observed inverse relation between fertility and economic status or income as the point of departure for explaining fertility. Considering the wealthy, he argued that the reasons for high fertility among them had disappeared even at an early stage of development since the labour of children and wives was of relatively little importance. Among the poorer classes, as long as there existed a demand for child labour, parents acted rationally in having a large number of children. The birth rates of the poor would decline only when the demand for this type of labour declined and the average quality of the labour demanded increased.<sup>279</sup>

115. Among the theories and models of economic development in which population appears as an integrated variable is that developed by Leibenstein. Leibenstein argues that the quasi-stable equilibrium, characteristic for the backward subsistence economy, can only be overcome by a strong displacement or stimulus, since the income-raising forces of a positive displacement (such as technological progress, emigration and, especially, a fortuitous increase in capital) set in motion other forces which tend to depress income (such as increased consumption, pressure on resources, institutional rigidities and particularly, population growth). Unless the displacement is strong enough and beyond the maximum of the income-depressing factors, reaching the so-called critical minimum

effort, the economy will return to its subsistence equilibrium. In this scheme Leibenstein assigns great importance to population as an endogenous variable. Population growth, through the relations which exist between its basic determinants (fertility and mortality) and income, is regarded as a function of levels of living. Mortality is thought to be negatively related to income, the reasoning being that higher wages, better food, shelter, medical care etc. associated with an increase in income will lower mortality. Fertility is determined by a great number of factors, but up to a certain point motivations for larger families will predominate. After that, fertility is likely to decline with further gains in income. In explaining the factors which create the motivations for smaller rather than for larger families, Leibenstein holds that both in the less developed and in the developed economies, parents are rational in their decisions and will desire an extra child only when the costs are smaller than the satisfactions. He distinguished three types of utility which can be derived from an additional birth: the utility of a child as a source of personal pleasure to parents; as a future productive agent contributing to the family income, and as a potential source of the parents' security during old age. These utilities would be weighted against the costs of an additional child—including the direct costs of maintenance, food and clothing and the indirect costs of opportunities forgone, such as the limited possibilities for mothers of young children to work, lost earnings during gestation and lowered mobility for the family. While in subsistence economies the utility of an additional child may outweigh its costs, in the course of economic development these utilities and costs are affected in a manner conducive to the establishment of the small family norm. These changes take the form of income effects involving the lower income of and decreased opportunities for child labour; the greater security at higher income at old ages and the higher direct and indirect costs of children; the survival effect related to the income effect and to the implications of an initial fast decline in infant mortality; mortality declines at higher ages in a later stage, and the occupational distribution effect related to the specialization and division of labour. These motivations to fertility reduction, according to Leibenstein, cannot be expected to develop in the early stages of improvement. Thus, when as the result of a positive displacement, mortality declines in response to the increased income, fertility may not immediately follow and a fertility lag arises. Where the displacement is not strong enough, fertility will not decline and the economy, under the pressure of the income-decreasing effects of a higher population growth, will return to a stationary state. Thus only where the displacement is such that decreasing utility and increasing costs for an additional child will take effect and be realized, will fertility decline and population growth slow down. The income-raising factors thus having been stimulated beyond the maximum of the income-depressing forces, the economy is on its way to development.<sup>280</sup>

116. A model similar to that of Leibenstein, but with a less complete treatment of population variables, was formulated by Nelson. According to Nelson, many of the under-developed countries are caught in the low-level equilibrium trap characterized by a stable equilibrium level of *per capita* income at or close to subsistence requirements. Capital formation is low and if the capital stock is accumulating, population is rising equally fast, thus precluding the possibility of increases in the amount of capital per worker. Nelson's model is built around three basic variables: income, investment and population growth. Since the model is short-run, changes in the birth rate are ignored and changes in population growth can result only from mortality. Mortality is supposed to be determined by the level of *per capita* income until the latter reaches a certain level beyond which it has little effect on mortality. Assuming production to be a function of capital stock, including land and population, Nelson shows that *ceteris paribus* average income per head can increase only if the rate of capital formation exceeds that of population growth. Small injections of capital may have no permanent effect since the consequent increase in income will tend to be swamped by population increase and only massive capital formation would make it possible to escape the equilibrium trap.<sup>281</sup>

117. A different interpretation of economic development and the role of population is found in Jorgenson's two-sector model. His basic hypothesis concerns the existence of two economic sectors—the advanced modern, or manufacturing, and the backward, traditional or agricultural—with different production functions. He assumes diminishing returns in agriculture; constant returns in industry and constant neutral technological change in both sectors. Capital formation is determined by the growth of the manufacturing labour force, by the terms of trade between the two sectors, and by the Malthusian law of population. More specifically, population growth depends on the supply of food *per capita* and the force of mortality. The latter is assumed given and can be altered only by changes in medical science. The birth rate depends on the supply of food *per capita*, but may attain a biological or social maximum provided the supply of food is sufficient. Taking the case where there is only the agricultural sector and distinguishing, moreover, between a situation where population growth is at its maximum and where it is still below that level and a function of *per capita* income, Jorgenson determines under which conditions a low-level equilibrium trap will exist and shows that, given diminishing returns, under these circumstances only the introduction of new techniques or measures of birth control would make it possible to escape this trap. When output per head is increasing, however, an agricultural surplus is generated and the development of the manufacturing sector becomes possible. This process is accompanied by a continuous change in production and by a transfer of population towards the manufacturing sector. Population will grow at its maximum rate and in the absence of technological change, capital and output will grow at the same rate.

<sup>281</sup> Nelson, "A theory of the low-level equilibrium trap ..." (1956).

Jorgenson concludes that the critical conditions separating the economy caught in the low-level equilibrium trap from that capable of sustained growth is the existence of a persistent agricultural surplus, the sufficient condition being that technological progress increases more rapidly than the combined effects of diminishing returns in agriculture and population growth.<sup>282</sup>

118. A different approach was taken by Hagen, who contended that a satisfactory population theory should account for three types of population growth—high population growth due to high birth rates and declining death rates caused by exogenous factors, such as improved public health; high population growth due to high birth rates and declining death rates resulting from increasing income and technological progress; and low population growth due to low birth and death rates but with a slight rise in birth rates as observed recently in developed countries. In his model Hagen stressed the role of technological progress and formulated two hypotheses on fertility. The first one, the standard of living effect, assumed that above some level of income, fertility may decline. The second, the desire to perpetuate the family, supposed that the level of birth rates is determined by that of the death rate in so far as the former is adjusted to the latter by the desire of the typical family to have two children to grow up to parenthood. The basic long-run rate of growth of population is thus fairly low but positive. However, the desire to have at least two children is not rational. It is embedded and a fertility lag will result when death rates are declining. This lag varies with the speed and conspicuousness of the decline in the death rate but the lag may be between some fifteen years up to several generations. The effect of exogenous declines in death rates in a system at the subsistence level, as in many developing countries, may cause *per capita* income to fall to a lower subsistence level. The reasoning is that when improved medical and health measures are introduced, it becomes possible for the population to reproduce itself at a lower level of income and the traditional Malthusian mechanisms will work. At the previous subsistence level population will grow and *per capita* income will decline progressively until the new, lower subsistence level is reached. Compared to the exogenously determined decline in the death rate, technological progress has not been fast enough to absorb its effect. Rapid technological progress would be sufficient to avert a decline in *per capita* income and eventually would produce a reduction in the birth rate.<sup>283</sup>

119. A view on population in the process of economic development different from that expressed by most other writers can be found in the writings of Hirschman. Although not developing a population theory in the strict sense of the word, he held that population pressure could be considered among the forces that may stimulate development. He formulated two propositions: first,

<sup>282</sup> Jorgenson, "The development of a dual economy" (1961). See also Cotta, *Analyse quantitative de la croissance ...* (1967), pp. 17-36.

<sup>283</sup> Hagen, "Population and economic growth" (1959). For a critical review, see Higgins, *Economic Development* (1959), pp. 318-323.

population pressure on living standards will lead to activities designed to maintain or restore the traditional standard of living; and secondly, such activities cause an increasing ability to control the environment and to organize the society for development. Such efforts are likely to be successful if a margin of possible improvements exist or if, as Hirschman argues, under-development is a state where labour, capital, entrepreneurship, etc. are

potentially available but need to be mobilized. Although recognizing that as an inducement mechanism population pressure ranks as the least attractive alternative, Hirschman still maintains that it presents the developmental forces with an opportunity to assert themselves.<sup>284</sup>

## Chapter IV

### FERTILITY

1. Human fertility, as a complex process responsible for the biological maintenance of society, constitutes an essential aspect of demographic studies. Within the limits established by physiological factors, a multiplicity of economic, social and cultural factors are the ultimate determinants of fertility levels and of their variations in different societies. A clear dichotomy of current fertility levels has been observed between countries classified as developed or developing according to their level of economic and social development. On the average, fertility is about twice as high in the developing as in the more developed regions of the world, and the distribution of countries by fertility level is distinctly bi-modal, with relatively few countries at intermediate levels. The study of the factors related to high fertility levels, and those associated with fertility decline, assumes great importance in view of the high rate of population growth now experienced by most developing countries that is generally considered to be a deterrent to their rapid economic development.

2. After presenting information on levels and trends of fertility in the various areas of the world, this chapter reviews the current state of knowledge regarding the limits imposed by physiological factors affecting fertility, and then discusses the customs and practices which influence fertility by way of such variables as age at marriage and use of contraception. The subsequent sections examine the underlying factors associated with the long-term decline of fertility in industrialized countries, and with the different levels of fertility currently prevailing in high-fertility, developing countries and among different segments of population within countries. Finally, there is a discussion of prospects for future fertility change in high-fertility and low-fertility countries.

#### A. Levels and trends of fertility

3. According to a United Nations study, the "countries with birth rates above 30 and gross reproduction rates above 2.0 are found almost exclusively in Africa, Asia and Middle and South America, while countries with rates below these levels are located, with few exceptions, in the economically more advanced regions".<sup>1</sup> For the

<sup>1</sup> United Nations, *Population Bulletin* ... (1965), pp. 1-2. The crude birth rate is generally computed as the number of births in a year per thousand of the mid-year population. The gross reproduction rate is defined as the average number of live daughters that would be born to a hypothetical female birth cohort surviving to the end of the reproductive age span and subjected to a specified set of age-specific fertility rates (i.e., the number of births per 1,000 women in each age group).

TABLE IV.1. ESTIMATED CRUDE BIRTH RATES AND GROSS REPRODUCTION RATES FOR MAJOR AREAS AND REGIONS OF THE WORLD, 1965-1970<sup>a</sup>

Major areas and regions	Crude birth rate (births per 1,000 population)	Gross reproduction rate
World total .....	34	2.3
Developing regions .....	41	2.7
More developed regions .....	19	1.3
Africa .....	47	3.1
Western Africa .....	49	3.2
Eastern Africa .....	47	3.1

<sup>a</sup> For the developing regions, the figures are estimates of the order of magnitude and are subject to a substantial margin of error.

world as a whole, the estimated crude birth rate was about 34 in 1965-1970; it was about 41 in the developing regions and 19 in the more developed regions (see table IV.1). Among the developing regions, the birth rate was estimated to be highest in Africa (47), as compared with 44 in South Asia, 38 in Latin America and 32 in

East Asia. There are a few countries of low fertility within these regions, most notably Japan and Israel in Asia, and Argentina and Uruguay in Latin America. Average crude birth rates in the principal more developed regions in 1965-1970 ranged from 18 in Europe and the USSR to 24 in Oceania. Exceptions to the prevailing low levels of fertility in these regions include Albania and the non-European population of Oceania.<sup>2</sup>

#### 1. AREAS OF LOW FERTILITY

4. Countries with currently low fertility (i.e., crude birth rates below 30 or gross reproduction rate below 2.0) have all moved from a previously much higher level of fertility in the course of development. Research on eighteenth-century history suggests, however, that crude birth rates were mostly less than 40 and, on occasion, as low as 30 in Northern and Western Europe well before the major decrease in fertility started.<sup>3</sup> Crude birth rates of about 37 in pre-revolutionary France, 32 to 35 in Sweden, and 29 to 33 in Norway in the eighteenth century have been estimated. In Finland the rate rose as high as 44 to 45 between 1750 and 1765, but was below 40 in the earlier decades of the century.<sup>4</sup> With the exception of the Finnish rate, these values for the crude birth rate are below the level currently experienced in the majority of developing countries. In the United States and Canada, crude birth rates were much higher than in Europe in the eighteenth and early nineteenth centuries. The very high level of fertility among early settlers in Canada has been brought out by the investigations of Henripin,<sup>5</sup> while Coale and Zelnik have written that "the birth rate in the United States at the beginning of the nineteenth century was markedly higher than ever recorded for any European country and is equalled in reliably recorded data only by such unusually fertile populations as the Hutterites and the inhabitants of the Cocos-Keeling Islands".<sup>6</sup> Birth rates in the 1850s in the United States were between 42 and 43, and then declined steadily to under 35 by 1878; reductions continued up to 1933, when the low level of 16.7 was reached.<sup>7</sup> In the USSR and Eastern Europe, birth rates before the start of the fertility decline were also higher than in eighteenth-century Northern and North-Western Europe. In the second half of the nineteenth century the Russian crude birth rate was nearly 50, and as late as 1913 stood at 47, while in

Bulgaria, Poland, Romania and Yugoslavia the rate was around 40 in the early years of the twentieth century.<sup>8</sup>

5. Ryder provides the following rough time-table for the passage of a number of countries into the low-fertility category: 1830s — France; 1840s — Ireland; 1880s — Switzerland, Belgium; 1890s — Sweden, Denmark, England and Wales, Scotland, Australia, New Zealand; 1900s — Netherlands, Norway, Germany, United States; 1910s — Canada, Finland, Austria, Hungary, Czechoslovakia; 1920s — Italy, Spain, Portugal; 1930s — Poland, Bulgaria, Romania; 1940s — USSR; 1950s — Japan, Yugoslavia.<sup>9</sup> Other countries with low fertility include Argentina, with a crude birth rate below 30 since the late 1920s; Uruguay, with a trend rather similar to that of Argentina but with insufficiently reliable statistics to pinpoint its date of entry into the low-fertility category; Israel, where the crude birth rate has been below 30 since 1954; and China (Taiwan), Hong Kong, Mauritius, Puerto Rico, Singapore, and Trinidad and Tobago, whose crude birth rates dropped below 30 in recent years.<sup>10</sup>

6. The trend in crude birth rates since 1900 for a number of low-fertility countries is shown in table IV.2. Among these countries, birth rates fell through the 1920s until the mid-1930s, but with some irregularity in the USSR, and with the German rate showing an early recovery from the very low level of the depression years, perhaps as a result of legislation favourable to family formation. Since the Second World War, crude birth rates in Northern and Western Europe and countries of European settlement in North America and Oceania have been generally higher than in the 1930s. However, the decline continued in Eastern and Southern Europe, the USSR and Japan, all areas in which the birth rate before the Second World War was still relatively high.

7. A narrowing of the range of crude birth rates of low-fertility countries has been particularly noticeable since 1960, and by 1969 nearly half the countries shown in table IV.2 had crude birth rates between 16 and 18. Some of these countries which had relatively high fertility in the post-war period, such as Canada, New Zealand, the Union of Soviet Socialist Republics and the United States, experienced falls of 3 to 8 points in their crude birth rates between 1960-1964 and 1969. On the other hand, in Austria, Denmark, Sweden, Switzerland and the United Kingdom (England and Wales), where fertility was somewhat below the average level for low-fertility countries in the 1950s, crude birth rates rose in the early 1960s. By the end of the 1960s, however, a downward trend was in evidence in all of these countries.

8. In most low-fertility countries the trend of the gross reproduction rate has been generally similar to that of the crude birth rate, with a decline through the 1920s and the early 1930s followed by a levelling off or a slightly increasing trend continuing through the early 1940s.<sup>11</sup> Trends in the gross reproduction rates for a number of

<sup>2</sup> While the average crude birth rate for Australia and New Zealand was only 20, for the remainder of Oceania it was above 40.

<sup>3</sup> Detailed analytical studies of fertility in Europe prior to the late eighteenth century have been made only in respect of a few villages or groups of villages in France, England and Flanders, and of the aristocracy. Such studies include Gautier and Henry, *La population de Crulai* ... (1958); Ganiage, *Trois villages de l'Île-de-France* ... (1963); Sogner, "Aspects of the demographic situation ..." (1963); Hollingsworth, *The Demography of the British Peerage* (1964); Henry, *Anciennes familles genevoises* ... (1956).

<sup>b</sup> Three-year average.

<sup>c</sup> For one year only.

<sup>d</sup> Two-year average for specified and subsequent year.

these countries since the Second World War are given in table IV.3. With one exception, the most recent rates shown in the table (those for 1967) vary between 1.0 and 1.4, a much smaller range than that of the late 1930s.<sup>12</sup>

9. Fertility trends in Japan did not parallel those characteristic of European populations. Morita has shown that nineteenth-century official birth rates considerably understated the true fertility level, and he estimates that birth rates were in the low 30s in the latter half of the nineteenth century; thereafter they began to climb.<sup>13</sup> According to Taeuber, there is some evidence of fluctuations in the first part of the present century, with some reduction between 1915 and 1919, followed by a marked rise in the early nineteen-twenties. The small declines noted thereafter were not sufficient to constitute the country's entry into the low-fertility category, as rates continued in the high 20s and low 30s. It was only after widespread fertility controls made their appearance in the late 1940s that signal reductions took place, and birth rates well under 30 were not recorded until the 1950s.<sup>14</sup>

10. Tables IV.2 and IV.3 show that, in the middle 1960s, fertility was lowest in Hungary, where the crude birth rate averaged around 14 and the gross reproduction rate was consistently below unity. The only other countries with gross reproduction rates below unity in one or more years of this period were Romania and Japan.<sup>15</sup> The fertility level in the USSR exceeded that in most

countries of Western Europe before 1960, but subsequent declines brought the gross reproduction rate to 1.17 by 1967.

11. The broad demographic aspects of the decline in fertility from a high to a low level have been summarized by Ryder on the basis of still incomplete data as follows:

"The primary demographic source of the fall in fertility was a decline in the mean completed parity of married women from the neighbourhood of seven [children] to a level below three. Parity distributions were progressively attenuated at the higher levels, with a tendency toward a pronounced mode at two. From a timing standpoint, the decline was achieved by cessation of childbearing at progressively earlier marital durations rather than by delayed initiation of marital fertility or longer birth intervals."<sup>16</sup>

12. The trend towards low-parity families is illustrated by the distribution of Norwegian marriages by year of marriage and number of children. Henry has analysed selected Norwegian census data relating to women married in their twenty-fifth year in the form shown in table IV.4. For women married between 1876 and 1890, the average number of children born alive exceeded six; for women married in 1930, the average number of children born alive was 2.65. This reduction in mean completed family size was achieved by reductions in the percentage of high-parity families and increases in the proportion of families with none or few children.<sup>17</sup> In Czechoslovakia, an analysis of population census data for 1930, 1950 and

SOURCE: Henry, "La fécondité des mariages en Norvège ..." (1958), p. 139.

1961, made it possible to trace the structure of completed fertility of five-year marriage cohorts since the eighteen-seventies. These data reveal a decrease in the average number of children per married woman from 6.4 to 2.2 in Czech regions, and from 6.1 to 3.2 in Slovak regions.<sup>18</sup> Data from a 1960 fertility survey carried out in the USSR showed substantial reductions in completed fertility for successive female birth cohorts, beginning with the 1895-1899 cohort, as well as changes in age patterns of childbearing.<sup>19</sup> The post-war period has seen a reversal in the trend toward childless and one-child families in such Western European countries as Norway, Switzerland, France and Italy, together with a large increase in families with two or three children, a very slight increase in those with four or five children, and little change in the small proportion of families with six or more children. Present trends in Western Europe are such that mean family size appears to be moving toward an average of 2.5 or 2.6 children per marriage.<sup>20</sup>

13. In Canada and the United States, as in Western Europe, there are fewer couples with no children, or only one, and more with moderate-sized families of two, three or four.<sup>21</sup> Campbell provides as an illustration of this trend the fact that 45 per cent of the women born in the United States between mid-1908 and mid-1909 had had no children or only one by age 50, as compared with only 24 per cent of the women born between mid-1927 and mid-1928 by age 35. Nor has the rise in completed

fertility in Canada and the United States since the Second World War in any sense been brought about by an increase in the proportion of couples with large families.<sup>22</sup>

14. Since the First World War, the relative contribution to the level of fertility on the part of women over 35 years of age in industrialized countries has continuously decreased and the magnitude of the decreases in fertility in the 1920s and the 1930s was progressively greater with the increased age of women. The "baby boom" in a number of low-fertility countries following the Second World War was a reflection of increased fertility among younger women. In most cases downward trends in the rates among women in older ages continued.<sup>23</sup>

15. In low-fertility countries women's childbearing tends to be concentrated in a narrower range of ages than in high-fertility countries. In fact, it has been shown that, on the average, three-fifths of total fertility in countries with gross reproduction rates below 2 results from births to women between 20 and 29 years of age, whereas in high-fertility countries the corresponding percentage is less than one half.<sup>24</sup> Recent age-specific fertility rates for a number of low-fertility countries are given in table IV.5. Three patterns can be observed: an early-peak fertility type (e.g. Hungary, Romania and the United States) in which the 15-19 age group of women makes a relatively large contribution to fertility and the peak occurs at ages 20-24; a broad-peak type (for example Australia, Canada, New Zealand and the United Kingdom (England and Wales)) where fertility within each country for the age groups 20-24 and 25-29 is nearly equal; and a late-peak type (for example Italy, the

<sup>18</sup> Jureček, "Ukazatele plodnosti žen z výsledků sčítání lidu" (1966), p. 2.

<sup>19</sup> For women 45 to 49 years of age, average family size had declined from 5.0 for the 1895-1899 birth cohort, to 3.4 for the 1910-1914 cohort. Boyarsky *et al.*, *Kurs demografii* (1967), p. 216. Similar changes have been observed in the Ukraine. See Steshenko, "Opyt primeneniia metoda kogort dlia ..." (1966).

<sup>20</sup> Biraben, "Prevailing fertility situation ..." (1967).

<sup>21</sup> Keyfitz, writing of Canada, says that "... all statistically recognizable groups seem to be converging on a norm. People exercise their increasing freedom to have the same number of children as their neighbours, in the narrow range of two to four, and to have them at the same ages." Keyfitz, "New patterns in the birth rate" (1962), pp. 41-42.

<sup>22</sup> Campbell, "Recent fertility trends ..." (1967), p. 201.

<sup>23</sup> United Nations, *Recent Trends in Fertility* ... (1958), pp. 17-24. The diminishing contribution of older women to total fertility between 1938-1939 and 1962-1963 in the Soviet Union is clearly shown in Vostrikova, "Female fertility and methods of studying ..." (1967), p. 241. A similar trend for Greece between 1934-1938 and 1956-1960 is shown in Valaoras, Polychronopoulou and Trichopoulos, "Control of family size in Greece ..." (1965), pp. 268-269.

<sup>24</sup> Compiled from United Nations, *Population Bulletin* ... (1965), table 7.2.

Netherlands, Spain and Switzerland) in which the peak occurs at ages 25-29. These patterns are closely related to age at marriage.<sup>25</sup> Japan and Ireland are shown to be exceptional, the former because of the unusually high proportion (48 per cent in 1964) of total fertility contributed by women in a single age group, that from 25 to 29,<sup>26</sup> and the latter because of the relatively high fertility of the 30-34 age group.<sup>27</sup>

## 2. AREAS OF HIGH FERTILITY

16. Adequate birth registration data are still lacking for many developing countries, and it has been necessary to estimate their fertility levels from census and survey data where possible. As a result of the growing abundance of such data and through the application of new analytical techniques,<sup>28</sup> estimates of fertility levels have recently

become available for many high-fertility countries in Africa, Asia and Latin America, though in some cases these estimates are of a relatively low order of reliability. The very high birth rate estimated for Africa (47 per 1,000 population in 1965-1970) is based to a large extent on census and sample survey data, and is subject to considerable error. For Nigeria, which has the largest population of any country on the continent, the age structure of the population, as divided into five broad age groups in the 1952-1953 census reports, has thus far provided the only basis for estimating fertility levels, and little reliance can be placed on the crude birth rate estimate of 53-57 from this source.<sup>29</sup> More recent analysis,

even under conditions of changing mortality. Given age distributions from successive population counts, or an age distribution from one population count and additional information such as the growth rate of the population, it is possible to derive estimates of vital rates. See, for example, United Nations, *Methods of Estimating Basic Demographic ...* (1967), and ———, *Le concept de population stable ...* (1966). Other advances have resulted from the extension of sampling procedures for obtaining vital rates, for example through periodic surveys of households or continuous recording of events. See Ahmed and Krotki, "Simultaneous estimations of population growth ..." (1963); Das Gupta, "Determination of fertility level ..." (1958); India, *Fertility and Mortality ...* (1963); Arretx G., "A method of estimating demographic rates ..." (1967).

<sup>29</sup> This estimate was obtained by calculating various age ratios from the census data and comparing them with corresponding ratios in stable population models, assuming levels of mortality that appeared to be appropriate for Nigeria. United Nations, *Population Bulletin ...* (1965), p. 32.

<sup>25</sup> See Acasádi, "Demographic variables ..." (1967), p. 184.

<sup>26</sup> Present-day fertility patterns in Japan are characterized by a small number of births with long intervals during the early marriage period, and almost complete restriction of births after ten years. Aoki, "Showa 37-nen dai 4-ji shussanryoku chosa kekka ..." (1965).

<sup>27</sup> Age-specific fertility rates for women in their thirties are higher in Ireland than in any other low-fertility country, despite the comparatively large proportion of Irish women remaining single at these ages; thus, a comparison of fertility rates for married women only would show an even greater differential between Ireland and other low-fertility countries.

<sup>28</sup> One technique involves the application of the concept of the stable population, since it has been shown that the age structures of population with unchanging fertility remain relatively stable,

however, has confirmed that fertility in Nigeria is high, though probably not as high as the rates mentioned above would indicate.<sup>30</sup> Sample surveys have recently provided estimates of fertility levels in many countries of former French Africa for which such measures were previously lacking; however, various tests applied to some of these data have suggested the types of errors which may afflict them.<sup>31</sup>

17. The birth rate for East Asia shown in table IV.1 reflects the rather moderate estimate for mainland China, the world's most populous country, where little is known about fertility levels and trends. Based on fragmentary information, estimates of China's birth rate have ranged from about 35 to 45 per 1,000 population; the United Nations has considered a figure near the lower limit more probable for the early 1960s.<sup>32</sup> Reliable vital registration data are lacking also for India, which comprises about half the population of South Asia. However, sufficient information is available from other sources to document a birth rate in the low 40s for that country.<sup>33</sup> Less certain are the fertility levels of such large populations as those of Pakistan and Indonesia. For Pakistan, neither the existing vital registration system nor recent population censuses have so far yielded satisfactory data for estimating the birth rate; various recent estimates have generally placed the crude birth rate at around 50 or above.<sup>34</sup> One estimate based on information obtained in the 1961 census of Indonesia suggests a crude birth rate in the neighbourhood of 43, while different assumptions applied to the same census data have suggested a higher rate.<sup>35</sup>

18. In Latin America adequate vital registration data are available for a larger segment of that region's population than is the case in Africa and Asia. The region's largest country, Brazil, has no comprehensive vital registration, however, although all available measures indicate high rates of fertility, especially in the rural areas. According to Mortara, the birth rate in the early 1950s was between 42 and 44. A variety of other fertility indices also indicate prevailing high levels, but the possibility of some slight declines in recent years is not ruled out.<sup>36</sup> Fertility levels in tropical South America as a whole are above the average for the Latin American region, as are those of the Central American mainland.

Mexico, the largest country in the latter region, has good vital registration data indicating a crude birth rate of around 44.

19. The data which have recently become available for the world's developing countries suggest surprisingly wide variations in fertility levels between one subregion and another. Thus, in Africa, there appears to be a belt of very high fertility extending across West Africa from Guinea and Mali to Niger and Nigeria, composed of countries whose gross reproduction rates are estimated at 3.3 or above, and in Latin America equally high gross reproduction rates have been estimated for Costa Rica, El Salvador, Guatemala and Honduras. On the other hand, there is a zone of much lower fertility centred in the Congo Basin in Africa, and countries of only moderately high fertility are found in the Caribbean area and the temperate zone of South America. In Asia, a group of countries in the south-east, including the Philippines, Cambodia, Thailand and the East Malaysian states of Sabah and Sarawak, have estimated gross reproduction rates of 3.2 and higher. There is a Chinese cultural zone of rather moderate fertility, with gross reproduction rates not exceeding 2.8. This zone includes China (Taiwan), Hong Kong and Singapore, and it probably includes mainland China. Pakistan appears to have very high fertility, but a zone of somewhat lower fertility, with estimated gross reproduction rates of 2.5 to 2.7, covers India, Nepal, Burma and Ceylon.<sup>37</sup> Weaknesses in the existing bases for making estimates of the fertility level in many of these areas must, however, be emphasized.

20. Reliable data for studying long-term fertility trends are not available for a representative group of high-fertility countries. Those countries for which reasonably accurate trend data are available are, for the most part, geographically small, and many have attained a comparatively more advanced level of economic and social development. As can be seen from table IV.6, in some of these countries there has been a noticeable downward trend in fertility, either over a long period of time, as in Puerto Rico and Chile, or more recently, as in Mauritius, Trinidad and Tobago, China (Taiwan) and Singapore. In Jamaica, the birth rate appears to have increased during the 1950s, though by the late 1960s it had fallen. Mexico is shown to have experienced a remarkably stable birth rate over a long period of time and the same was true of the coloured population of South Africa until very recently. Also falling into the group of countries with rather stable fertility are Thailand, the Philippines and the United Arab Republic; while there are no reliable time series of birth statistics for these countries, the available evidence does not suggest a downward trend in their birth rates.<sup>38</sup> Various estimates of long-term fertility trends in India indicate either that

<sup>a</sup> Registration data notably incomplete.

<sup>b</sup> Three-year average.

<sup>c</sup> Four-year average.

<sup>d</sup> Two-year average.

the birth rate has shown only a moderate decline since earlier in the century, or else that it has remained practically unchanged.<sup>39</sup>

21. In analysing birth rate trends for developing countries, care should be taken to avoid interpreting a reduction in the birth rate over a period of a very few years as a certain indication that the population concerned is moving permanently to a lower level of fertility. A recent United Nations study found "Few instances ... of long-continued upward or downward trends in high-fertility countries, resulting in large changes comparable to the past declines in countries where fertility is now low. In this sense, the data imply that the levels of fertility in high-fertility countries generally have probably been relatively stable during recent decades. On the other hand, it seems that rather large short-term variations and appreciable longer-term increases and decreases have not been uncommon. Some reservations should therefore be attached to the assumption often made in studies of the demography of high-fertility countries, that their fertility has generally remained nearly constant for long periods in the past."<sup>40</sup>

22. In high-fertility countries, women in the early and late periods of the reproductive cycle contribute relatively more to total fertility than do their counterparts in low-fertility countries. Thus, women over 35 were found to contribute 21 per cent, and women under 20 years 10 per cent, of total fertility, on average, whereas the corresponding proportions in low-fertility countries were only about 15 per cent and 6 per cent, respectively. Recent age-specific birth rates for a number of high-

fertility countries are given in table IV.7. It is seen that even in the peak childbearing ages fertility rates are higher in developing countries than in those that are more developed. The high fertility rates shown for women under 20 in such countries as India, Jamaica and Venezuela are related to marital status patterns in those countries, as is the greater concentration of childbearing at older ages in Singapore (see section C below). In Puerto Rico, where there has been for a decade a gradual decline to a moderate level of fertility, the figures of age-specific fertility for the older women tend to be noticeably low; this is an illustration of the fact that a fertility decline in its early stages usually affects women over 35 years of age much more than younger women. The data on age-specific fertility for African populations, derived mainly from sample surveys, indicate a distinctive pattern in that the proportion of total fertility contributed by women under 20 years of age exceeds that in most other parts of the world, a finding related to prevailing customs of early marriage.<sup>41</sup>

## B. Physiological variables affecting fertility

23. Fecundity refers to "the capacity ... to participate in reproduction (i.e., the production of a live child)", whereas fertility "means actual reproductive performance".<sup>42</sup> Although fecundity cannot be measured directly in statistical terms, the study of the many physiological factors involved makes it possible to assess in general terms the childbearing capacity of human populations.

<sup>41</sup> Data in this paragraph are based on United Nations, *Population Bulletin* ... (1965), chap. 7, and table IV.7 of the present study.

<sup>42</sup> United Nations, *Multilingual Demographic Dictionary* (1958), para. 621. It is, however, important to note that demographers writing in French and Spanish use the terms *fécondité* and *fecundidad*, respectively, in the sense in which the term "fertility" is used in English, and *fertilité* and *fertilidad* to correspond to "fecundity".

<sup>39</sup> See, for example, Coale and Hoover, *Population Growth and Economic Development* ... (1959), pp. 45-50; Davis, *The Population of India and Pakistan* (1951), p. 69; Ghosh, "The trend of the birth rate in India ..." (1956), pp. 62, 67; Saxena, "Estimates of birth rate ..." (1967).

<sup>a</sup> Wherever possible, rates include births to women under fifteen years and fifty years and over, respectively.

<sup>b</sup> Now known as the People's Republic of the Congo.

Data, when available, on population groups with extremely high birth rates help to establish estimates of the effective upper limits of human fertility, which at the same time may be regarded as minimum estimates of human fecundity. Some such estimates from demographic literature are presented at the beginning of this section. The remainder of the section is devoted to a review of the principal physiological factors with the particular end in view of examining the possible influence of variations in fecundity on fertility trends and levels.

### 1. MAXIMUM FERTILITY RATES

24. Many attempts have been made to estimate the upper limit of human fertility. Kuczynski considered that crude birth rates have probably never exceeded 65 per 1,000 population.<sup>43</sup> In pre-revolutionary Russia the birth rate in several provinces was over 60.<sup>44</sup> Crude birth rates of this magnitude are, however, only possible when childbearing commences at a very young age. Coale and Tye have estimated that in a community such as the Hutterites, among whom fertility is very high but child-

bearing does not commence on average until women are in their early twenties, the crude birth rate would not exceed 56.<sup>45</sup> In the United States in the early days of growth a favourable age distribution and nearly universal marriage combined to give a crude birth rate above 50.<sup>46</sup>

25. More instructive than the crude birth rate are measures of fertility based on women of reproductive ages. In developing a model of a population "likely to be bearing children at a rate which could not be far from the physiological upper limit", Glass and Grebenik took the fertility of rural Irish women who, according to the 1911 census, had been married for 30-35 years. Total fertility for these women varied with age at marriage. For those marrying under age 20 it was 8.81, and for those marrying at 20-24 it was 8.04. At the other extreme, women marrying at ages 40-44 showed a total fertility of only 2.05.<sup>47</sup> Cocos Island women marrying at age 14 or 15 had averaged 10.82 children at age 45, 10.29 children when married at 16, 9.32 when married at 17, 8.75 when married at 18, 7.31 when married at 19, and 6.60 when

married at 20 or 21.<sup>48</sup> Among the Hutterites, an average of 11.9 confinements per woman were recorded for women whose last child was born when they were 45 or over; for those bearing their last child when aged 40-44, the mean number of confinements was 10.9.<sup>49</sup>

## 2. AGE LIMITS OF THE REPRODUCTIVE PERIOD

26. The commencement of the period of potential fertility in the female is usually taken as the age of menarche, that is, the onset of the first menstruation. The presence in the blood of certain hormones secreted by the pituitary glands initiates the menstrual cycle. However, menarche is merely one stage in the gradual process of adolescence, and the first menstruation does not always signify firm establishment of the ovulatory cycle. The fact that as long a period as three years may separate the onset of menstruation from the establishment of the regular ovulatory cycle has led to the formulation of the theory of adolescent sterility, which is illustrated by the apparently low fertility among young unmarried females in certain primitive societies, despite the practice of premarital sexual activity.<sup>50</sup> Indian experience tends to confirm this theory. Several surveys in that country show that women in their late teens at first cohabitation bore a child after relatively short intervals, in contrast to women whose marriages were consummated at an earlier age.<sup>51</sup>

27. Menarcheal age is not a constant, but varies both in time and between countries. According to data assembled by Tanner, "menarche in Europe has been getting earlier during the last hundred years by between three or four months per decade" and now stands at about thirteen years. Various environmental changes (among which nutrition is the most obvious) are thought to be chiefly responsible for this change, although genetical factors may also play a role. Data for Chinese girls in Hong Kong illustrate the influence of both the environmental and genetical factors: menarcheal age for rich girls is nine months earlier than for poor girls, although even the latter have menarche no later than most better-off Europeans. Indeed, the Chinese in Hong Kong have one of the earliest recorded menarches, while the genetic threshold for East Europeans is perhaps below that for West Europeans. At one time it was believed that menarcheal age was lower in hot than in temperate climates, but today climate is not considered to have much influence, if any; relevant information on this score, however, is sparse. The fact reported by Tanner that no group in the world "is currently known in which menarche occurs

anything like as late as in Europe a century ago"<sup>52</sup> suggests that earlier age at menarche coupled with early age at marriage in the high-fertility countries today may account in part for their higher level of fertility compared with that found in Europe just prior to the fall of fertility. During the fall, however, the effect of declining menarcheal age, while it could not have been very great owing to the late average marrying age prevailing at that time, must have been to retard somewhat the decrease in fertility that was in process.

28. There is less information on changes in the age at menopause than on changes in the age of menarche. It should be noted that the birth of the last child is usually at a markedly lower age than menopause, and this is to be expected even in high-fertility communities in view of the gradual decline in fecundity with advancing age.<sup>53</sup> Pearl found that mean age at menopause in twenty series of data ranged from 44.0 years to 49.4 years,<sup>54</sup> while Kamat and Kamat reported a mean age at menopause of 42.2 years for Indian women.<sup>55</sup> According to Tanner, the very few inquiries made in the United Kingdom on the subject indicated that the menopause age had been pushed back and that at the present time it might be nearly 50 years on average.<sup>56</sup> To the extent that economic and social development is associated with a later age at menopause and thus with higher fecundity, this is another factor that would have slowed down the historical decline in fertility in countries of currently low fertility.

29. The attainment of sexual maturity is not so protracted in the case of the male as for females. On the other hand, there is no definite physiological event or change in the male with which the cessation of the capacity to reproduce can be identified. The male span of reproductive capacity is considerably longer than that of the female. Despite this longer span, it is necessary to recognize the possibility that the "... apparent decline of fecundity in women with advancing age may be in part a function of declining fecundity in men ...".<sup>57</sup>

## 3. POST-PARTUM STERILITY

30. It is now generally accepted that women undergo a period of sterility after the birth of a baby, and that the length of this period varies from one woman to another. Experts differ in their estimates of the mean length of post-partum sterility. Tietze noted that in a sample of Hutterite women, among whom there was little premarital intercourse, the average interval between age at

<sup>48</sup> Smith, "The Cocos-Keeling Islands ..." (1960), p. 111.

<sup>50</sup> Hartman, "On the relative sterility ..." (1931); Ashley-Montagu, *Adolescent Sterility* ... (1946); and his *The Reproductive Development of the Female* ... (1957), pp. 80-165.

<sup>51</sup> Lorimer, "Capacity for procreation ..." (1954), p. 47; Chandrasekaran, "Physiological factors affecting ..." (1963), p. 92. See also Sovani and Dandekar, *Fertility Survey of Nasik* ... (1955), pp. 80 ff.

<sup>52</sup> Tanner, "The trend ..." (1965), pp. 49 ff. For rich girls in Hong Kong the mean age is 12.5 years, for "average" girls 12.8 years, and for poor girls 13.3 years. Lee, Chong and Chan, "Sexual maturation of Chinese girls ..." (1963), p. 391. Among Ashanti girls, menstruation usually begins about the sixteenth year. Fortes, "A demographic field study in Ashanti" (1954), pp. 296-297.

<sup>53</sup> Thus Eaton and Mayer found for the Hutterites that the probability of a woman conceiving in a given year diminished rapidly after the age of 38. Eaton and Mayer, *Man's Capacity to Reproduce* ... (1954), pp. 24-26.

<sup>54</sup> Pearl, *The Natural History of Population* (1939), p. 51.

<sup>56</sup> Tanner, "The trend ..." (1965), p. 60.

<sup>57</sup> Lorimer, *Culture and Human Fertility* ... (1954), p. 49.

marriage and age at first confinement was about 18 months and the average interval between subsequent births was 25.5 months. These figures, adjusted to take account of foetal deaths, suggest a mean post-partum sterility of about 6.3 months.<sup>58</sup> James, taking into account the fact that coital rates decrease with increasing duration of marriage, considered 6.1 months as a plausible estimate.<sup>59</sup>

31. Studies of populations which are presumed to practise little or no deliberate birth limitation have shown that the birth interval is much shorter following an infant death in the first month or two of life than when the infant survives the first year or two. In the Cocos Islands, for instance, the birth interval after a neo-natal death averaged 1.70 years, while the interval averaged 2.45 years after the birth of an infant surviving the first two years of life.<sup>60</sup> This and other studies have attributed the apparent reduction in the period of post-partum sterility following the early death of an infant to the practice of breast-feeding, which is believed to prolong the period of post-partum amenorrhoea.<sup>61</sup> Various scholars have commented upon the apparent widespread custom of lactation in pre-industrial societies, the effect this practice would have in holding fertility levels down and the likelihood that a decrease in the duration of breast-feeding would constitute a factor tending to increase fecundity during the period when fertility is in its phase of secular decline.<sup>62</sup> A more recent study, however, has questioned the extent of the influence of breast-feeding on birth intervals, and thereby on fertility levels. Knodel and Van de Walle, in their analysis of data from Bavaria, Baden and Hesse prior to the historical decline of fertility in these regions, found that, "even if the physiological connection between lactation and amenorrhoea is strong, it is not an important factor in explaining the variations in regional fertility in these German states" because the relatively high inverse correlation existing between breast-feeding and fertility virtually disappears when infant mortality is held constant, whereas the high correlation between infant mortality and fertility persists even in those areas where lactation was not widespread and there was "little opportunity for mortality to influence fertility by interrupting lactation".<sup>63</sup>

#### 4. INVOLUNTARY FOETAL MORTALITY AND OTHER FORMS OF STERILITY AND SUB-FECUNDITY

32. In addition to the universal forms of sterility and sub-fecundity—such as sterility before and after the reproductive age span, declining fecundity towards the

end of the span and post-partum sterility—there exists a variety of pathological conditions, diverse and difficult to classify logically,<sup>64</sup> which affect the fecundity only of certain individuals in a society. These may be of genetic or congenital origin, or they may result from certain diseases. Among the genetic factors are lethal types which inhibit intra-uterine survival of the foetus, thereby resulting in miscarriage or foetal death. Genetic factors may also be indirectly responsible for sub-fecund states or complete sterility. Congenital disorders can impair fertility by producing some organic malfunction of the reproductive system, such as that resulting from congenital syphilis.

33. One such kind of sterility or sub-fecundity about which much has been written is involuntary foetal mortality. The index most commonly used for measuring foetal mortality is the ratio of late foetal deaths (i.e. those occurring after six months of pregnancy) to total births, or less frequently to live births. Observations on involuntary foetal loss for the first six months of pregnancy are few in number. French and Bierman used the results of observation of about 3,000 pregnancies in Hawaii in the period 1953-1956 to calculate monthly foetal loss ratios, and found that foetal mortality is very high early in pregnancy, after which there is a steep drop until the rate becomes stabilized after the sixth month.<sup>65</sup> On the basis of this survey and other evidence, Bourgeois-Pichat suggested that on average about 30 per cent of conceptions result in foetal death, and that the elimination of such deaths might increase the gross reproduction rate by about half that amount, or by 15 per cent.<sup>66</sup> For lack of adequate data, his calculations were based on rather arbitrary assumptions, and he emphasized the necessity of further research. Of particular relevance to the study of factors affecting fertility is Bourgeois-Pichat's assumption that, whereas the foetal mortality of the first six months is "a kind of biological mortality", the level of the plateau reached at the end of six months is influenced by environment and "is highest when the conditions are least favorable".<sup>67</sup> Thus, the improved environment associated with economic and social development would promote lower foetal mortality and, thereby, higher fertility; here then is another factor which would have exerted an opposite effect during the transitional decline in fertility.

34. Among the diseases associated with sub-fecundity are the venereal diseases, malaria and plague. There is some indication that venereal disease might have played a part in the relatively low fertility among females involved in "visiting unions" in the West Indies.<sup>68</sup> Venereal diseases are known to be widespread in large

<sup>58</sup> Tietze, "Reproductive span ..." (1957), p. 92.

(1965). For a discussion of the effects of breast-feeding on post-partum sterility, see Tietze, "The effect of breastfeeding ..." (1963).

<sup>62</sup> See, for example, Henry, "Caractéristiques démographiques des pays sous-développés ..." (1956), pp. 170-171.

<sup>63</sup> Knodel and Van de Walle, "Breast feeding, fertility and infant mortality ..." (1967), p. 127.

<sup>64</sup> Some of these conditions are discussed in Penrose, "Genetical aspects of human infertility" (1963), p. 94.

<sup>65</sup> French and Bierman, "Probabilities of fetal mortality" (1962).

<sup>66</sup> Elimination of foetal deaths would not increase fertility by as much as 30 per cent, since the period of post-partum sterility and the duration of pregnancy are longer in the case of a live birth.

<sup>67</sup> Bourgeois-Pichat, "Relation between foetal-infant mortality and fertility" (1967).

<sup>68</sup> Roberts, "Some demographic considerations of West Indian federation" (1957), p. 284.

parts of Africa, and are believed to be responsible in part for the particularly low fertility of certain tribes.<sup>69</sup> It has been contended that malaria produces involuntary abortions and stillbirths.<sup>70</sup> In India, differentials in fertility have been noted which may have some association with the control of malaria.<sup>71</sup> On the other hand, Newman's investigation of the effects of the control of malaria on vital rates in Ceylon and Guyana found no conclusive evidence of a relationship between the eradication of the disease and levels of fertility.<sup>72</sup> Outbreaks of plague have also been followed by periods of low fertility, in Catalonia following the epidemic of 1650 and in the parish of Colyton in Devon, England, following the violent outbreak of 1645-1646. In these two instances, both of which have been the subject of detailed analysis, low fertility persisted for several decades.<sup>73</sup>

35. Quantitative data on the incidence of sterility attributable to the separate factors discussed above are not available in a form that would permit trends within countries or differences among countries to be identified. Even the total incidence of sterility from all causes is often difficult to determine for a particular population. In populations in which marriage is nearly universal and which do not practise deliberate family limitation, inferences of sterility and sub-fecundity are sometimes made indirectly from data on the childbearing experience of females. Although the proportion of women who remain childless diminishes with advancing age, it may remain appreciable in some of these populations. Romaniuk found, in analysing the results of a 1956-1957 sample survey in the Democratic Republic of the Congo, that in certain districts of the country around 35 per cent of the women over 45 years old had borne no children, while in other districts the proportion was as low as 5 per cent. Over the country as a whole, the data indicated that an average of 20 per cent of women who attained the age of 45 had never had a child.<sup>74</sup> Exceedingly high rates of childlessness were also found among Afro-Arab women in Zanzibar, especially in the urban area.<sup>75</sup>

36. Data obtained from a number of censuses and sample surveys in Africa show a clear inverse relation between the percentage of women beyond age 45 years or thereabouts reported as having borne no children during their lifetime and the estimated level of fertility among these countries, childlessness being most frequent

where fertility is relatively low, and *vice versa*.<sup>76</sup> In India, the National Sample Survey found that 7.5 per cent of couples had had no children after twenty-two years of marriage, and estimates of sterility at about this level have come from many other countries.<sup>77</sup> The frequency of involuntary sterility can be as low as 3 or 4 per cent. Grabill and Glick report that in 1910 only about 3 per cent of Russian-born females in the United States who had ever been married were childless at the end of the childbearing period.<sup>78</sup> Canadian census data for 1941 indicate that, in rural Quebec, where completed fertility of women who married before their twentieth birthday was exceedingly high, only 4.0 per cent of these women were childless.<sup>79</sup> Unfortunately, estimates of sterility based on the proportion of childless women at the end of the reproductive age span cannot be used for ascertaining the extent to which secular changes in fertility are due to changes in sterility in societies which practise deliberate birth limitation.

37. The kinds of changes reviewed above in the physiological factors affecting reproduction would have tended to affect fertility during the transition, if at all, by increasing rather than decreasing it.<sup>80</sup> Nevertheless, the literature on fertility decline contains a number of theories or hypotheses which attempt to account for some or all of the decline in terms of physiological or psychophysiological factors. For example, there were the much-discussed theories of Spencer<sup>81</sup> and other nineteenth-century authors that fertility declines by a natural biological law as the level of living rises. In the early decades of the present century, biological views were elaborated by Gini, who considered that nations have a period of vigour followed by a time of decay which manifests itself by a decline in fertility. The inhabitants lose the desire to procreate, but, unaware of their lowered fecundity, they use contraceptives to prevent births which they are biologically incapable of having.<sup>82</sup> For most demo-

<sup>69</sup> United Nations, *Population Bulletin* ... (1965), pp. 23-24.

<sup>77</sup> Das Gupta *et al.*, *Couple Fertility* (1955), p. 45. However, data of this kind must be used with caution on account of a tendency among older women to forget the children born to them who died in infancy or to misinterpret the census or survey question to refer to children now alive and who still live with them. In the 1960 Mexican census, for example, 29 per cent of women aged 50 and over were reported as childless, whereas the corresponding figure for women aged 40 to 49 years and therefore not yet at the end of the reproductive span was only 22 per cent. <sup>79</sup> Lorimer, *Culture and Human Fertility* ... (1954), p. 29.

<sup>80</sup> In recent decades, the crude birth rates in certain of the lesser developed Central Asian Republics of the USSR have risen: between 1940 and 1963, for example, from 29.4 to 40.6 in Azerbaijan SSR, from 30.6 to 35.1 in Tajik SSR, from 33.6 to 36.2 in Uzbek SSR. Valentei, *Teoria i politika narodonaseleniia* (1967), p. 162. While improved registration and changes in age structure contributed to these increases, it is believed that improved health conditions, which, as indicated above, may have operated in the past as a force for increased fertility during the period of transitional decline, were also a factor.

graphers, Gini's thesis is so speculative that it is scarcely worth refuting.

38. More recently a biological explanation for declining birth rates has been presented by Castro, who considered that consumption of proteins brings down fertility, while protein deficiency keeps it high. His main evidence is a table showing meat consumption and fertility for a number of countries, and indeed the meat-eating peoples of the world are those with the fewest children.<sup>83</sup> Castro did not consider the possibility that both the eating of meat and the reduction of family size go hand-in-hand with improved socio-economic status. As evidence against Castro's analysis, various studies have indicated that well-nourished women in developed countries would have at least as high fertility as the impoverished in developing countries were it not for the practice of contraception among the former.<sup>84</sup> Henry has pointed to the very high fertility of the Hutterites, as an argument that, in the absence of voluntary birth limitation, fertility does not necessarily fall when diet improves.<sup>85</sup>

39. A number of authors have suggested that various factors in modern life may have reduced reproductive capacity, such as an increase in alcoholism or venereal disease,<sup>86</sup> the excessive practice of sports by women, the employment of women in factories,<sup>87</sup> the frequent bathing with soap by women (since soap is a spermicide)<sup>88</sup> and a decrease in sexual intercourse due to the excessive nervous strain of modern urban life.<sup>89</sup> Some of these factors have been suggested as having a contributory influence rather than as causing the major part of the decline in family size. None of them has been accepted generally, and some have been heavily criticized. For example, it has been pointed out that there is no proof that the frequency of alcoholism or venereal disease increased during the period when the birth rate declined.

40. Although the physiological factors affecting fertility from one point of view are distinct from and exert their effect apart from the social, economic and cultural factors, many physiological factors are genuine variables either in the sense of displaying variation among different populations or of varying over time within populations, and these changes or variations are to some extent subject to the influence of social and economic conditions. Both the extent to which the individual physiological factors may vary as well as the extent to which they may be affected by socio-economic factors are not yet well understood and constitute areas for further research.

### C. Customs and practices affecting fertility

41. The physiological factors discussed above, along with certain customs and practices relevant to fertility,

<sup>83</sup> Castro, *The Geography of Hunger* (1952), pp. 70-72, 161-162.

<sup>89</sup> Hankins, "Has the reproductive power of western peoples declined?" (1932), pp. 187-188.

have been classified as "intermediate" variables in that they constitute the variables "... through which any social factors influencing the level of fertility must operate".<sup>90</sup> The present section consists of a review of the non-physiological intermediate variables—the customs and practices—and their relation to fertility, using as a frame of reference the widely-known Davis and Blake classification<sup>91</sup> of intermediate variables. Attention is given principally to those variables which have been most investigated and which are thought to be largely responsible for differences in fertility level among high-fertility populations or for the dramatic shift from high to low fertility that has taken place in the countries where economic development is most advanced.

42. One of the advantages of the Davis-Blake framework is that it helps bring into sharper focus existing differences in research interests. Fertility trends and differences are sometimes studied in terms of general or over-all fertility, with attempts made to isolate the variable or variables responsible for the observed changes or differences. On the other hand, changes in legitimate fertility, because they reflect changes resulting from deliberate birth control, are often the primary focus of study. Such different approaches sometimes lead to non-comparable and apparently contradictory conclusions. In the field of differential fertility, for example, generalization has become exceedingly difficult because some investigators describe differentials in terms of general fertility whereas others work only with marital fertility and sometimes maintain that a differential is not genuine unless age at marriage is held constant.

### 1. THE INTERMEDIATE VARIABLE FRAMEWORK

43. The Davis-Blake classification of the "intermediate variables" affecting fertility is as follows:<sup>92</sup>

<sup>90</sup> Davis and Blake, "Social structure and fertility ..." (1956), p. 211.

<sup>91</sup> *Ibid.*

<sup>92</sup> Davis and Blake, "Social structure and fertility ..." (1956), p. 212. Most writers on this subject distinguish a set of factors corresponding to the Davis and Blake intermediate variables, even though the designation "intermediate" may not always be used, or the variables always arranged in the same order or listed so exhaustively. Freedman and Nag incorporate the Davis and Blake variables directly into their work. [Freedman, "Fertility; statement by the Moderator" (1966), pp. 37 and 48; Nag, *Factors Affecting Human Fertility* ... (1962), pp. 10-11.] Sauvy also identifies a class of variables similar to the Davis and Blake variables, which, except for certain types of sterility, he calls the "social factors" of fertility. [Sauvy, *Théorie générale de la population* ... (1966), vol. 2, chap. 7.] Ulanis calls them "causes" of fertility as distinct from the more fundamental "factors". [Ulanis, "Dynamics of the birth rate ..." (1967), pp. 237-238.] Coale and Henry's use of the intermediate variables in the formulation of the concepts of natural and controlled marital fertility are discussed in paras. 46-48 below. Kozlov groups the intermediate variables into three classes: physiological, nuptiality and family planning variables. [Kozlov, "Some causes of the high fertility ..." (1967), p. 156.] The British Royal Commission on Population discussed the role of the nuptiality variables, and then of the voluntary and involuntary causes of the fall in family size (essentially the voluntary and involuntary variables of Davis and Blake). [United Kingdom, Royal Commission on Population, *Report* (1949), chaps. 3 and 4.]

I. Factors affecting exposure to intercourse ("intercourse variables")

A. Those governing the formation and dissolution of unions in the reproductive period

1. Age of entry into sexual unions
2. Permanent celibacy: proportion of women never entering sexual unions
3. Amount of reproductive period spent after or between unions:
  - (a) When unions are broken by divorce, separation or desertion;
  - (b) When unions are broken by death of husband

B. Those governing the exposure to intercourse within unions

1. Voluntary abstinence
2. Involuntary abstinence (from impotence, illness, unavoidable but temporary separations)
3. Coital frequency (excluding periods of abstinence)

II. Factors affecting exposure to conception ("conception variables")

A. Fecundity or infecundity, as affected by involuntary causes

B. Use or non-use of contraception:

- (1) By mechanical and chemical means;
- (2) By other means

C. Fecundity or infecundity, as affected by voluntary causes (sterilization, subincision, medical treatment etc.)

III. Factors affecting gestation and successful parturition ("gestation variables")

A. Foetal mortality from involuntary causes

B. Foetal mortality from voluntary causes

44. This framework divides the intermediate variables into three broad groups corresponding to three easily identifiable phases of the reproductive process: sexual intercourse, conception and parturition. As the authors emphasize, each one of the eleven intermediate variables is a variable in the sense that "it can operate either to reduce or enhance fertility". Consequently, the level of fertility of a population results from the joint effect of its values on all eleven variables. Further, a population, even though it may have a high fertility value on some variables, for example universal marriage at an early age, may none the less have a low or moderate fertility level because of low fertility values on other variables, such as the use of contraceptives or recourse to abortion (voluntary foetal mortality). Two populations may have approximately the same level of fertility despite very different values on all or most of the intermediate variables.<sup>93</sup>

45. Attention is called to another threefold classification into which the intermediate variables fall: some are designated as "voluntary" in that they constitute deliberate behaviour intended to exercise control over fertility;<sup>94</sup> the "involuntary" variables describe behaviour that is

unavoidable or beyond the control of the individual; the remaining variables are neither one nor the other because they are often not primarily directed towards the regulation or non-regulation of fertility. These distinctions, despite certain inconsistencies and difficulties in application, have proved useful in different kinds of research problems.

46. For example, Henry has developed the concepts of "natural" fertility and controlled fertility as a guide in the formulation of his investigations. Natural fertility, proposed as an improvement over the concept of maximum biological capacity (which, in practice, cannot be measured), is the fertility which exists in the absence of deliberate birth control. Populations displaying natural fertility have high fertility values on all four of the voluntary variables, that is to say such populations have little or no contraception, sterilization, induced abortions or voluntary abstinence from intercourse. In practice, Henry restricts his studies to the natural fertility of married women, in order to avoid the important although often unpremeditated effects on fertility of differences in nuptiality (variables number 1, 2 and 3).<sup>95</sup> Various writers, such as Bourgeois-Pichat and Coale, in addition to Henry, have discussed the relative importance of the different intermediate variables in accounting for observed historical differences in the natural fertility of married couples.<sup>96</sup>

47. Controlled fertility refers to all those differences or changes in the fertility of married couples produced by one or more of the intermediate variables involved in deliberate birth control. Coale and his team of international experts, working on the history of the decline of fertility in Europe, have adopted these concepts of Henry as working tools. One of the provisional hypotheses of the Coale project is that everywhere in Europe in the not-too-remote past populations were characterized by natural fertility among married couples. It is further hypothesized that the major fertility declines that followed are attributable essentially to the adoption of controlled fertility. Trends in marital fertility are being investigated for evidence of increased control of fertility with due caution for the recognized fact that all declines in marital fertility need not necessarily imply a spread in fertility control.<sup>97</sup>

48. The Coale project also takes into consideration the three intermediate variables relating to nuptiality by conceptually distinguishing in its research the separate effects on declining general fertility of changes in nuptiality and of increased recourse to controlled fertility.<sup>98</sup> Davis himself, with his "theory of the multiphasic response" has used the intermediate variables in a similar manner to advance a different hypothesis, "generally overlooked because of our preoccupation with the contraceptive issue", that Japan and the countries of north-west Europe reacted to the "persistent excess of births over deaths with virtually the entire range of possible responses.

<sup>93</sup> Davis and Blake, "Social structure and fertility ..." (1956), p. 213.

<sup>94</sup> While only three of the variables—voluntary abstinence, voluntary fecundity or infecundity, and voluntary foetal mortality—are explicitly labelled as voluntary, it is implicit that the use of contraception (although not always its non-use) also belongs in this category.

... each industrializing nation tended to postpone marriage, to increase celibacy, to resort to abortion, to practise contraception in some form, and to emigrate overseas".<sup>99</sup>

## 2. AGE OF ENTRY INTO SEXUAL UNIONS (AGE AT MARRIAGE); PERMANENT CELIBACY

49. Of the variables relating to nuptiality, age at marriage and the proportion of persons in a population who never marry are the two believed to be the most significant in accounting for observed variations in fertility levels, and considerable research into their effect on fertility has been conducted and is still in process. Historically, a close interdependence has tended to exist between these two variables in the sense that, for a given population, a high fertility value on one variable (i.e., early age at marriage) is generally found to be associated with a high fertility value on the other (i.e., a small proportion of never-married) and vice versa;<sup>100</sup> it is therefore convenient to discuss them together.

50. There is an important difference between the two variables, however. Although permanent celibacy, to the extent that it is not offset by a higher incidence of illegitimacy, tends to have relatively the same depressing effect on fertility in both high-fertility and low-fertility populations, the effect of age at marriage is greatest in high-fertility populations where the practice of family planning is largely unknown and family size is closely related to the duration of marriage spent in the reproductive age span. It has been maintained that, in the absence of illegitimate births, a rise in the age at marriage in such populations can yield a marked reduction in fertility.<sup>101</sup> Agarwala has calculated that the Indian birth rate might be reduced as much as 30 per cent by 1991-1992 if all Indian women married after the age of nineteen.<sup>102</sup> Coale and Tye have shown, taking data relating to Chinese and Malays in Singapore as an illustration, that postponement of marriage can reduce crude birth rates and population growth even when completed family size is not thereby reduced.<sup>103</sup> In countries of moderate fertility levels, a more modest association has been found between age at marriage and size of family.<sup>104</sup> In low-fertility countries, on the other hand, a close relation between fertility and age at marriage cannot be observed.<sup>105</sup>

51. Hajnal, in his study of European marriage patterns, established on a solid empirical basis that the countries of Europe west of an imaginary line running roughly from Leningrad to Trieste, were characterized at the end

of the nineteenth century by a pattern of late age at marriage and a high incidence of permanent celibacy which, for convenience, he termed the "European" pattern. With the exception of intermediate patterns in Greece, Hungary and the overseas countries of European colonization (such as the United States), the European marriage pattern "... is unique for all large populations for which data exist or reasonable surmises can be made ...". In Northern and Western Europe some three-quarters of the women were still single by age 20 to 24, whereas elsewhere in Europe three-quarters were usually married in this age group; similarly, the proportion of women remaining single around their fiftieth birthday was nowhere below 10 per cent and often above 15 per cent in the "European" pattern, but scarcely ever reached as high as 5 per cent in Eastern Europe and was often of negligible dimensions elsewhere.<sup>106</sup> The later age at marriage and the higher proportions of never-married often shown by marital status data for countries in Latin America and the Caribbean are probably attributable in large part to the many consensually married persons in these countries who are often reported as unmarried.<sup>107</sup>

52. Hajnal also marshalled evidence which "suggests the general conclusion that the European pattern originated before the eighteenth century", although most probably not before the beginning of modern times in the sixteenth century.<sup>108</sup> This runs counter to the theses advanced in some earlier writings on this subject that the growth of urbanization, the lengthening period of education, the increasing proportion of women working outside their homes and other factors would make for an increasing age at marriage.<sup>109</sup>

53. As Hajnal points out, however, his thesis is not new. Many writers from Malthus on have attributed at least in part to low nuptiality the relatively low level of fertility in Europe prior to the Industrial Revolution compared with the developing countries today.<sup>110</sup> Based

<sup>106</sup> Hajnal, "European marriage patterns ..." (1965), pp. 101-106.

<sup>107</sup> *Ibid.*, p. 105; United Nations, *Demographic Yearbook*, 1962 ... (1963), table 13; ———, 1963 ... (1964), table 34; also, Hollingsworth, "The marriage rate ..." (1966), pp. 4-5.

<sup>108</sup> Hajnal, "European marriage patterns ..." (1965), pp. 107, 134. Census data cross-tabulating age and marital status cannot be found for most countries before the middle of the nineteenth century, although for Norway and Denmark this information is available as far back as the beginning of the nineteenth century and back to 1750 in the case of Sweden. Other types of evidence, therefore, have to be resorted to. According to the Royal Commission, barriers to marriage, reflecting fears of overpopulation, existed in many parts of Europe up to the eighteenth century. [United Kingdom, Royal Commission on Population, *Report* (1949), p. 35.] Knodel has noted that legal restrictions on marriage were imposed in many German states in the seventeenth and eighteenth centuries in order to combat growing pauperism. [Knodel, "Law, marriage and illegitimacy ..." (1967), pp. 279-280.] Pauperism was also a problem even in the sixteenth century in England. Dunlop quotes the Common Council of London in 1556 as giving "the over hastie marriages and over sone setting up of householdes of and by the young folk of the said citie" as a justification for establishing the requirement that guild apprentices must be twenty-four years of age before coming out of servitude. on estimates provided by Henry, the legitimate gross reproduction rate in Sweden in 1750 would have been 40 per cent higher if Sweden had had the marital structure of Algeria in 1948.<sup>111</sup> What is original in Hajnal's work is that he has systematically compared the countries of northern and western Europe with all the other countries of the world and then pushed the historical analysis as far back into the past as possible.<sup>112</sup>

54. Much has been written about the Indian institution of child marriage. Only 5 per cent of females in the age group 20 to 24 were still single according to the 1931 census of India (including Pakistan).<sup>113</sup> Hindu tradition decrees that a girl should marry before she attains puberty.<sup>114</sup> A gradual decline in the frequency of child marriage has been noted since the late nineteenth century in response to changing public sentiment as well as the enactment of legislation, the most recent being the revision of the Hindu marriage law in 1955, which established the minimum age for girls at 15 and boys at 18.<sup>115</sup> Henry has suggested that the prohibition of remarriage for widows may explain the apparently lower level of fertility in India (as compared with many other developing countries) despite the prevailing early marriage age.<sup>116</sup> Other possible explanations which have been mentioned are the Hindu custom of women returning to their parents' home for confinement and the ruses that parents often use to keep their daughters at home long after the marriage ceremony.<sup>117</sup>

55. In societies where there is much illegitimacy, the relationship between age at marriage and level of fertility is less definite. Marriage in such societies may cement or give legal sanction to unions long in existence. This is common in the Caribbean and in much of Latin America,<sup>118</sup> and it results in very high average ages at formal marriage. The available evidence suggests that unstable forms of marital unions tend to depress fertility in the

West Indies. In Guyana, Jamaica and Trinidad, the fertility of common-law marriages has been shown to be less than that of formal marriages, while "visiting" unions (i.e., unions in which the partners do not cohabit regularly) are of still lower fertility.<sup>119</sup> On the other hand, data from fertility surveys in a number of Latin American cities indicate that for women in common-law marriages, the average number of live births is higher than for formally married women in Caracas, Mexico City, Panama and Rio de Janeiro, lower in Bogotá, and about the same in Buenos Aires and San José. Further analysis of the results of these surveys will, however, be necessary to determine the effect of different forms of marital status on fertility.<sup>120</sup>

56. One of the most controversial aspects of nuptiality concerns its historical role in the transition from high to low fertility which has accompanied the process of economic development. Davis, in his theory of the multiphasic response referred to above, has shown that postponement of marriage—but not celibacy—is one adjustment adopted by the Japanese in order to reduce their fertility. "The proportion ever married among girls aged 15-19 fell from 17.7 in 1920 to 1.8 per cent in 1955, and for women 20-24 it fell from 68.6 to 33.9."<sup>121</sup> Standardization techniques have shown that the crude birth rate in Japan, which fell from 32.3 per thousand in 1930 to 17.2 in 1960, would have fallen only to 24.4 if the female marital structure had not changed during the interval.<sup>122</sup>

57. According to Davis, a change in nuptiality patterns was one of the "responses" contributing to the transitional decline in fertility in northern and western Europe. However, the relationship between nuptiality patterns and fertility levels during the major decline in these areas is not clear. The data which Davis presents for Ireland support his hypothesis, as nuptiality there fell precisely during the period when fertility was declining. Ireland was an extreme example of the European marriage pattern, since age at marriage and the proportion never married rose to higher levels there than in any other country. In Sweden, on the other hand, the proportion of women ever married in the younger ages (15 to 29 years) fell sharply between 1750 and 1870, but levelled off after that,<sup>123</sup> i.e., just around the time when the major decline in fertility began.<sup>124</sup>

58. Preliminary results from the Coale research project mentioned earlier have been published for five countries (Norway, France, and England and Wales, in addition to Ireland and Sweden). Coale's index of the proportion

of married women,<sup>125</sup> presented for 1870, 1900, 1930 and 1960, shows the three additional countries to be more consistent with the Swedish nuptiality pattern than with the Irish. In all of the countries except Ireland, this index appears relatively constant between 1870 and 1930, and then, from 1930 to 1960, it rises at least 15 per cent in all the countries (including Ireland).<sup>126</sup>

59. Pending more complete returns from the research of Coale and his associates, Ryder's characterization of the demographic transition in western Europe and its overseas heirs in North America and Oceania appears best to describe the existing state of knowledge. Taking into account the recent increases in nuptiality (in the form of lower age at marriage and/or higher proportions of ever-married) that have taken place once the control of marital fertility has been acquired, he distinguishes four phases in the following sequence: "high nuptiality and high marital fertility; low nuptiality and high marital fertility; low nuptiality and low marital fertility; and finally high nuptiality and low marital fertility". The countries falling outside the Northern and Western European pattern of low nuptiality are in a position to abbreviate the sequence by omitting the two intermediate stages and passing directly from high nuptiality and high marital fertility to high nuptiality and low marital fertility. Apparently the countries of Eastern Europe have already made the transition in this way, while Japan and probably the Soviet Union have not.<sup>127</sup>

### 3. AMOUNT OF REPRODUCTIVE PERIOD SPENT AFTER OR BETWEEN UNIONS

60. As has already been pointed out, the proportion of women currently married in each reproductive age group does not depend exclusively on the average age at which women marry and the proportion who never marry. It is also affected by the incidence of divorce, separation and death of spouse, by the extent to which divorcees and widows remarry and separated persons become reunited, and by the amount of time elapsing before remarriage.<sup>128</sup>

61. There exists also another nuptiality variable, polygamy, which does not fit well into the Davis and Blake

framework. There has been considerable discussion and some research into the possible effects of this practice on fertility. Most of the speculation leans towards the hypothesis that polygamy (the marriage of one man with several women) depresses fertility levels partly because of lower coitus rates per wife and a stricter observance of customs relating to sexual abstinence. The research that has been done in this area for the most part supports the hypothesis,<sup>129</sup> although a number of studies have shown no systematic inverse relationship between fertility levels and polygamy.<sup>130</sup> Interest in the subject, however, is largely academic as there are no sizable populations in which the practice of polygamy, with its potential for lower fertility, is extensive enough to have a significant impact on over-all fertility.

62. The total impact of the divorce rate on fertility is problematical. On the one hand, divorce clearly reduces the proportion of the reproductive period during which women are exposed to intercourse, and would thus tend to have a depressing effect on fertility. The magnitude of this effect depends on the extent of remarriage and the amount of time elapsing before remarriage. On the other hand, divorce may promote higher fertility by permitting sterile unions to be replaced by fruitful ones. The fact that a high proportion of divorced couples are childless<sup>131</sup> may be evidence that sterility has led to marital dissolution. Rowntree and Carrier remark that, "When childbearing was the expected sequel to marriage, involuntary sterility may have been a compelling motive for divorce".<sup>132</sup> Analyses of the relationship between fertility and divorce are sometimes oriented towards establishing the hypothesis that children constitute a deterrent to divorce. In societies where large families are valued, the threat of divorce may affect fertility by encouraging the wife to bear many children "to hold her husband, for children are a bond. The fear of divorce is ever present, but the chance of being divorced is greatly reduced with each additional child."<sup>133</sup> However, evidence of the relationship between marital stability and family size must be qualified by the fact that the number of children is a function of the duration of the union.<sup>134</sup> Divorce may contribute to higher fertility by making it possible for a

<sup>125</sup> This nuptiality index is essentially a weighted ratio of married women to all women in the reproductive ages. By its use of currently married women instead of ever-married women, it takes into account all three of the Davis and Blake nuptiality variables and, therefore, is affected not only by variations in age at marriage and in permanent celibacy, but also by variations in the time spent outside matrimony during the reproductive period (due to divorce, separation, death of spouse etc.).

<sup>126</sup> Coale, "Factors associated . . ." (1967), p. 209.

<sup>127</sup> Ryder, "The character of modern fertility" (1967), p. 30.

<sup>128</sup> Because human fertility is more conveniently studied in terms of female fertility, the Davis and Blake framework of intermediate variables does not include the dissolution of unions through the death of the wife as a factor affecting fertility. Female fertility rates (except for the less frequently used net reproduction rate) remain essentially unchanged by the death of wives, since these wives no longer make a contribution either to the numerator or the denominator of the ratio of births to population from which the rates are calculated. This simplification of defining fertility in terms of female reproductive behaviour is not consistently followed, however, and a certain amount of confusion can be found in the literature on this score.

<sup>129</sup> Muhsam, "Fertility of polygamous marriages" (1956), pp. 9-12; Dorjahn, "Fertility, polygyny . . ." (1965), pp. 52-53; Chad, Service de statistique, and France, Service de Coopération, *Enquête démographique au Tchad, 1964* . . . (1966), vol. 1, pp. 138-139.

<sup>130</sup> Busia, "Some aspects of the relation . . ." (1954), p. 347; France, Ministère de la France d'outre-mer, *Etude démographique par sondage en Guinée* . . . , vol. 1 [n.d.], pp. 42-43; Gabon, Service de statistique, and France, Service de Coopération, *Recensement et enquête démographiques, 1960-1961* . . . (1965), p. 92.

<sup>131</sup> For instance, 60 per cent of the divorces in Turkish cities are those of couples without children, according to Cillov, "Tendances des mariages . . ." (1963), p. 190. In the United States in 1960, 24 per cent of divorced women aged 35 to 44 were childless. Glick, "Marriage and family variables . . ." (1967), p. 211.

<sup>133</sup> Cleland, "A population plan for Egypt" (1944), p. 132.

<sup>134</sup> Jacobson, "Differentials in divorce . . ." (1950), p. 243.

number of persons to marry who would otherwise remain single. The hypothesis has also been advanced that "... a first marriage may more readily be contracted if the situation is viewed as one in which there is the possibility of a relatively easy divorce in the event of marital failure".<sup>135</sup>

63. It has been noted that, all other factors remaining constant, declining mortality during the demographic transition would have the effect of raising fertility, because fewer wives would be widowed before the end of their reproductive period; the combination of lower death rates and higher birth rates would result in an acceleration of the crude rate of natural increase. In reality, the effect of declining widowhood has often been to temper somewhat the declines in fertility resulting from the spread of family limitation practices or from modifications in some of the other intermediate variables which have either accompanied or followed declining mortality.

64. The effects of declining mortality on widowhood and fertility during the demographic transition are difficult to measure because the data are not usually available that would permit allowance to be made for the remarriage of widows. Using the large body of historical statistics available for Sweden, Ryder has demonstrated graphically the effects on fertility of improved mortality. An analysis of data for five-year female birth cohorts revealed that, despite a marked decline in nuptiality beginning early in the nineteenth century, the effects on fertility were "... practically nullified by contemporaneous changes in mortality" tending to increase the mean marital duration. Ryder's cohort index of "the proportion of total person-years married" (essentially the number of reproductive years spent in marriage as a proportion of the total number of reproductive years) actually declined gradually from 52 per cent to 48 per cent, whereas under the assumption of fixed mortality, the index would have declined sharply from 54 per cent to 44 per cent.<sup>136</sup>

65. In developed countries with low mortality rates, the proportion of widowed among women of reproductive age is small, and the effects of widowhood on total fertility are marginal. Where mortality rates are relatively high, however, as is the case in many developing countries, customs relating to the remarriage of widows may have an important bearing on fertility levels. The custom of discouraging remarriage of widows is particularly associated with Hindu tradition in India. Historically, the practice of suttee involved the immolation of the widow on the funeral pyre with her husband. Despite the banning of this custom in 1829, reluctance to remarry continued, even though an act was passed legalizing the remarriage of Hindu widows in 1856.<sup>137</sup> Some students of Indian population hold that the tradition of discouraging remarriage plays an important part in keeping fertility in India down to moderate levels when compared with

many high-fertility countries, and the decline in this tradition, it is considered, may bring an increase in the level of fertility.<sup>138</sup> Agarwala, however, maintains that the restriction "... was observed only by the upper castes and widow remarriages have always been common among the lower castes",<sup>139</sup> while Dandekar, on the basis of a demographic study of six Indian rural communities, found that widow remarriage depended largely on age at widowhood, the relationship being, of course, inverse.<sup>140</sup>

#### 4. VOLUNTARY ABSTINENCE (SOCIAL TABOOS ON SEXUAL INTERCOURSE)<sup>141</sup>

66. Taboos on sexual intercourse are observed among several societies, at times and under circumstances when its performance is deemed dangerous or unclean, in particular during menstruation, pregnancy, the post-partum period, and on certain ceremonial and religious occasions. Some of these taboos clearly do not affect fertility. Nag states, however, that Moslem and Hindu women in the West Bengal area of India are expected to abstain from intercourse on particular days of the year considered to be auspicious in their respective religions. Among the Hindus, the number of such days in the year varies from about eighty to nearly one hundred.<sup>142</sup> Admittedly, the influence on fertility of even this form of abstinence is difficult to demonstrate. Kirk, noting that ritual abstinence is apparently less common among Moslems than among Hindus, observes that this, together with their less frequent practice of post-partum abstinence, "may explain the somewhat higher birth rates of Moslems than Hindus in the Indian subcontinent ...".<sup>143</sup>

67. In order for taboos on sexual intercourse after childbirth to have any noticeable effect on fertility, the period of restraint must be relatively long, perhaps at least four months. Thus, Nag found a negative correlation between the duration of post-partum abstinence and the level of fertility when comparing fertility levels for population groups whose period of post-partum abstinence was one year or less with those groups who abstained for more than a year.<sup>144</sup> According to Fortes, Ashanti women are secluded for forty days after childbirth and then given a further forty days of convalescence. Such a custom is unlikely to affect fertility. Fortes contrasts this practice with "... the widespread African custom which prohibits intercourse between the parents of a nursing child until it is able to walk ...".<sup>145</sup> There is indication that such customs are eroding and Henry has noted this as one among several factors which in the course of industrialization would tend to promote higher fertility.<sup>146</sup>

<sup>138</sup> Davis, "Human fertility in India" (1946), p. 251.

<sup>139</sup> Agarwala, "Mean ages at marriage ..." (1963), p. 149.

<sup>140</sup> Dandekar, "Widow remarriage ..." (1963), p. 206.

<sup>141</sup> The "rhythm" method, which may also be classed as voluntary abstinence, is included among the means of contraception by Davis and Blake.

<sup>142</sup> Nag, "Family type and fertility" (1967), pp. 161-162.

<sup>143</sup> Kirk, "Factors affecting Moslem natality" (1967), p. 151.

<sup>144</sup> Nag, *Factors Affecting Human Fertility* ... (1962), p. 79.

<sup>145</sup> Fortes, "A demographic field study in Ashanti" (1954), p. 265.

<sup>146</sup> Henry, "Caractéristiques démographiques des pays sous-développés ..." (1956), p. 170.

<sup>135</sup> Ryder, "Measures of recent nuptiality ..." (1963), p. 294.

<sup>136</sup> Ryder, "The influence of declining ..." (1955). Declining mortality in fact also appears to have contributed to raise fertility in another way at the same time—by increasing the ratio of males to females in the young adult ages and, therefore, by making marriage to some degree more probable for these females.

<sup>137</sup> Nag, *Factors Affecting Human Fertility* ... (1962), p. 103.

Roberts and Tanner refer to the decay of the former general restriction on intercourse during the nursing period of a child in coastal Tanganyika, and cite the current restriction in this area as one of forty days after childbirth.<sup>147</sup>

#### 5. FOETAL MORTALITY FROM VOLUNTARY CAUSES (ABORTION)

68. Current knowledge of the extent of induced abortion is very limited, and is even less accessible for the past. The first systematic data are beginning to come from some of the countries which have liberalized abortion legislation, and particularly from Hungary, Czechoslovakia and Japan,<sup>148</sup> but any attempts to assess the number of abortions in countries where the operation is illegal must, at best, be plausible estimates with no claim to accuracy.<sup>149</sup> There are indications of its use under a wide variety of circumstances in primitive societies.<sup>150</sup> According to Landry, abortion, like various other methods of birth control, has been known since time immemorial, although its practice before the transition from high to low fertility had been very restricted.<sup>151</sup> It appears to have become an important factor influencing the level of fertility in almost all of the more developed countries in the transition period.<sup>152</sup> According to Carr-Saunders, "The opinion of those most closely in touch with the situation, such as doctors, seems to be that there has been in Germany and some other European countries a considerable, and perhaps a large, increase in this practice" while the birth rate was falling.<sup>153</sup> Sutter calls attention to the rapid development of the practice of self-abortion towards the end of the nineteenth century in the large cities of France. Resort to this practice apparently resulted from the increasingly repressive character of legislation against abortion which made it both more dangerous and more expensive to resort to an intermediary.<sup>154</sup>

69. In the socialist countries of Eastern Europe, with the exception of Albania and Eastern Germany, abortion has been legalized at various dates from 1955 onwards,<sup>155</sup>

<sup>147</sup> Roberts and Tanner, "A demographic study ..." (1959), p. 79.

<sup>148</sup> For a study of induced abortions in Hungary, see, for example, Miltényi, "A művi vetélések demográfiai jelentősége" (1964); for Czechoslovakia, see Srb and Kučera, "Potratovost v Československu v letech 1958-1962" (1963); for Japan, see Muramatsu, "Medical aspects ..." (1967), pp. 67-79.

<sup>149</sup> For estimates of the incidence of induced abortion in some Western European countries prior to 1940, see Glass, *Population Policies and Movements in Europe* (1940), pp. 54, 163, 279. See also Calderone, *Abortion in the United States* ... (1958), p. 180.

<sup>153</sup> Carr-Saunders, *World Population* ... (1936), p. 98.

<sup>154</sup> Sutter, "Sur la diffusion ..." (1960), p. 347.

<sup>155</sup> In the USSR in 1955, in Bulgaria, Poland, Hungary and Romania in 1956, in Czechoslovakia in 1957, and in Yugoslavia in 1960. Mehlan, "The socialist countries of Europe" (1966), p. 207. In the German Democratic Republic, the indications for legal abortion, which were somewhat liberalized in 1947, were in 1950 restricted to medical and eugenic reasons. See Mehlan, "Die Abortsituation in der Deutschen Demokratischen Republik" (1961).

on the general principle that a woman is entitled to have an undesired pregnancy terminated in a hospital or other institution. Statistics on abortion trends are not available from the USSR or Romania, but trends in the abortion rates in Bulgaria, Czechoslovakia, Hungary, Poland and Yugoslavia are presented in table IV.8. In discussing the effects of abortions on fertility, Klinger notes that "... in those countries where fertility was low before abortion was legalized, i.e., Bulgaria, Czechoslovakia and Hungary, the number of births began to decrease at a faster rate. On the other hand, in countries with higher fertility (Soviet Union, Poland, Yugoslavia) the decline in fertility started later, and with the exception of Poland, the rate of decline was lower ...". Countries with higher abortion rates were found to have lower birth rates.<sup>156</sup> In Romania, the abrupt revocation of the liberal abortion law in the last quarter of 1966 was followed by a sharp rise in the birth rate.<sup>157</sup>

70. Japan is another country which has legalized abortion under specified conditions in the post-war period. The idea of limiting births is not, however, new to the Japanese people, and it has been shown above that only moderately high fertility levels prevailed even in the nineteenth century. Before and during the Second World War the Government followed a pro-natalist policy, but this was reversed in 1948 with the passing of the Eugenic Protection Law, which, as revised in 1952, permits the termination of pregnancies "... if the health of the mother is endangered by the continuation of pregnancy or the delivery due to physical or economical reasons".<sup>158</sup> The very large reduction of fertility in the Japanese population between 1950 and 1956 was achieved mainly as the result of the use of abortion, but more recently contraceptive methods have been gaining popularity with the active encouragement of the Government.<sup>159</sup> From 1949 to 1958 the crude birth rate declined from 32.8 to 18.0, while during the same period the number of abortions per 1,000 population rose from 3.0 to 12.3. In 1958 there were 1.6 million births and 1.1 million abortions.<sup>160</sup> There is, however, a large incidence of

<sup>156</sup> Klinger, "Demographic effects of abortion legislation ..." (1967), p. 90. See also Mehlan, "The socialist countries of Europe" (1966), p. 212. For additional discussion of the significance of the legalization of abortion in Eastern Europe, see the following: Szabady, Tekse and Pressat, "La population des pays socialistes européens" (1966); Mauldin, "Fertility control in communist countries ..." (1960), pp. 187 ff.

<sup>157</sup> The birth rate climbed to 38-39 (computed on an annual basis) in July-August of 1967, the first months when the full effects of the new legislation were felt. By comparing these rates with the corresponding rates for 1966, Pressat estimates that there were 170 induced abortions for every 100 live births in the earlier period, and that the high birth rates experienced under the new legislation offer proof of the low level of contraceptive practice. Pressat, "La suppression de l'avortement légal ..." (1967). The rate has since been falling back again somewhat and averaged 29.5 for the first quarter of 1968. unreported induced abortion in Japan, and Muramatsu, taking 1955 as the year for analysis, has estimated that the total incidence of induced abortion may have amounted to twice the reported number.<sup>161</sup> In recent years the number of abortions has been falling,<sup>162</sup> probably as a result of the more widespread and effective use of contraception.<sup>163</sup>

71. In Latin America there are indications that the incidence of abortion is high, especially in cities, and constitutes a serious health problem because of the unsanitary conditions under which the illegal operation is often performed. Requena, in his study of abortion in Latin America, has developed the hypothesis that abortion is an intermediate phase of the process by which different sectors of a population in the course of economic and social development pass from uncontrolled fertility to family planning by contraception. The distinction between abortion and contraception is likened to that between curative and preventive medicine, the latter implying a mature and conscious attitude towards the problem. From studies in Chile, it appears that women begin to have recourse to abortion as they pass from the lowest to a medium socio-economic-cultural level. With still further education and participation in the economic and social life of the country, they increasingly acquire the foresight to use contraception for family limitation, resorting to abortion only in the event of contraceptive failure. The question is raised by Requena whether it is possible for the countries of Latin America to proceed directly from uncontrolled fertility to control by contraception instead of recapitulating the experience of Japan and the socialist countries of Eastern Europe.<sup>164</sup>

<sup>161</sup> Muramatsu, "Effect of induced abortion ..." (1960), p. 166.

<sup>162</sup> Muramatsu, "Medical aspects ..." (1967), p. 69.

<sup>163</sup> See, for example, Honda, "Senzen sengo no fufu shussan-ryoku ..." (1959); and Koya, *Pioneering in Family Planning* ... (1963).

<sup>164</sup> Requena, "Condiciones determinantes del aborto inducido" (1966); and his "Chilean programme of abortion control ..." (1967). In response to these problems a programme of comparative surveys on the incidence of induced abortions and the use of contraceptives in urban areas of a number of Latin American countries has been initiated by the United Nations Latin American Demographic Centre (CELADE).

## 6. VOLUNTARY INFECUNDITY (STERILIZATION)

72. Surgical sterilization is a device for permanently preventing conception. While the operation may be performed on either sex, it is a more simple procedure in the case of the male. In neither sex does it interfere with subsequent sexual performance or pleasure. Although sterilization is usually intended to be permanent, the male operation can often be reversed should the individual desire it.<sup>165</sup>

73. Japan is one of the countries where sterilization has been used as a means of fertility control. The Eugenic Protection Law of 1948 provided for sterilization essentially on eugenic grounds, but the protection of the life and health of the mother is also a prescribed ground for its application. From 1949 to 1965 over half a million sterilizations were performed under this Law, the great majority of them on women; the number of sterilizations moved up from some 5,700 in 1949 to reach a maximum of 44,500 in 1956 and then to decline gradually to 27,000 in 1965, but these official figures probably understate considerably the true incidence of sterilization, which may be from five to ten times as high.<sup>166</sup> Sterilization of males as a means of family planning has been given much importance in India, particularly in certain states.<sup>167</sup> In Puerto Rico, *La Operación*, as sterilization is called, has spread because of the willingness of medical workers to urge its acceptance on females.<sup>168</sup>

## 7. USE OR NON-USE OF CONTRACEPTION

74. Contraception, covering all non-permanent measures to prevent coitus from resulting in conception, can be divided into two broad classes—chemical-mechanical or appliance methods, and natural or non-appliance

<sup>165</sup> See Phadke, "Place of sterilization ..." (1964); Wood, "Female sterilization" (1964); and Ferber, "Male sterilization" (1964).

<sup>166</sup> Taeuber, *The Population of Japan* (1958), pp. 269, 281-282; and Muramatsu, "Medical aspects ..." (1967), pp. 79-82.

<sup>167</sup> The incidence of sterilization appears to be highest in Madras. See Repetto, "India: a case study ..." (1968). On the subject of sterilization in India, see also Dandekar, "Vasectomy camps in Maharashtra" (1963); Raina, "India" (1966).

<sup>168</sup> Hill, Stycos and Back, *The Family and Population Control* ... (1959), pp. 126-127, 180-181.

methods. The three non-appliance methods are *coitus interruptus* (withdrawal), the rhythm method, which consists of the avoidance of intercourse during the woman's fertile period, and total abstinence. *Coitus interruptus* is practised in many societies, both primitive and modern, and reference to its use in Genesis attests to its ancient establishment.<sup>169</sup> Among the chemical-mechanical methods are the condom or sheath used by the male; female methods include the diaphragm, the oral contraceptives introduced in the 1950s, the newly developed intra-uterine devices, jellies, creams and foams, as well as a variety of older and rather ineffective devices (e.g., the douche).

75. It is now generally accepted that contraception was the principal intermediate variable responsible for the shift from high to low fertility during the late nineteenth and early twentieth century. But, as Freedman has pointed out, evidence for the spread of contraception is largely by inference since "we have almost no historical trend data bearing directly on family planning practices".<sup>170</sup> The KAP-type of fertility survey (contraceptive knowledge, attitudes and practice) originated after the fertility reduction had been achieved so that in the course of the decline no attempt had been made to observe changes in contraceptive practice. Two sets of retrospective, longitudinal data from England are perhaps unique in the glimpse they afford. According to the Lewis-Faning 1949 study of a not very representative hospital population, the proportion of women ever having practised birth control increased progressively from only 15 per cent for women married prior to 1910 to 66 per cent for the 1935-1939 marriage cohort whose fertility was still incomplete. Furthermore, the proportion of women having used birth control was greater among those social classes whose fertility was lower.<sup>171</sup> Data from a fairly representative national sample in the 1959-1960 Marriage Survey showed similarly that among persons married before 1930 only 53.7 per cent had ever practised contraception, as compared with 72.8 per cent among persons married between 1940 and 1949.<sup>172</sup>

76. Among the types of indirect evidence on the role of contraception in the decline of fertility, the principal one has probably been the widespread general impression that the practice of birth control and abortion has increased greatly and that many people could have had more children if they so desired. Several features of the decline have been interpreted as pointing to the operation of family limitation: the speed of the decline, the pattern of its spread in neighbouring areas, in socio-economic groups and in religious groups, the greater decline in rates of child-bearing at long durations than at short

durations of marriage, the greater decline of fertility rates among older women than among younger women, and the increase in the apparent effect of economic fluctuations on fertility rates. In addition, data from numerous fertility surveys in recent years have generally shown that the use of contraception is much less frequent in high-fertility populations than in populations where fertility is low. In Turkey 28 per cent of the population were using some method of family limitation, according to a survey conducted in 1963.<sup>173</sup> In India, the Mysore Survey established that in Bangalore City in 1952 only 12 per cent of all couples reported having attempted to use some method of family limitation, abstinence being the method most frequently relied on.<sup>174</sup> Blake reports that 37 per cent of a non-clinic sample of Jamaican women had used some method of birth control, including abstinence.<sup>175</sup> In Lebanon among educated city dwellers more than 80 per cent of the women report some use of contraceptives.<sup>176</sup> Similarly, data from a survey of fertility in seven cities of Latin America showed, in general, an inverse relationship between the level of fertility and the proportion of married women ever having used contraceptives; the city with the lowest fertility—Buenos Aires—had the highest use of contraception (77.6 per cent) whereas Mexico City, where fertility was highest, had the lowest use of contraception (37.5 per cent).<sup>177</sup>

77. There has also been considerable interest in the findings of research into the *kinds* of contraceptive methods used during the decline of fertility in the West, and the implications of these findings with regard to the perspective for fertility in the high-fertility regions of the world today. Attention has centred on two aspects: the predominance, especially in Europe as opposed to the United States, of male methods such as withdrawal or the condom,<sup>178</sup> and the somewhat related point that the methods adopted required on the whole a high degree of sustained motivation.<sup>179</sup> The dramatic development of highly effective female contraceptive methods requiring a lesser degree of motivation has enhanced the possibility of a more rapid acceptance of family planning in the high-fertility countries where attitudes towards contraceptive practice are ambivalent and motivation is frequently reported as weak, but the question has also been raised whether the men in these reportedly male-dominated societies will find such methods acceptable and will readily relinquish their prerogatives in these matters.<sup>180</sup>

#### D. Factors related to past declines of fertility in areas where fertility is low

78. Any review of the factors responsible for past reductions of fertility in areas of low fertility must be prefaced by the acknowledgement that the phenomenon is not yet well understood, in part because of its extreme complexity and in part also because serious scientific interest and study in it did not begin until after the event had taken place. Most of the really relevant information was not collected and, except for what can be reconstructed by inference from other available historical data, is probably lost forever.<sup>181</sup> The historical decline of fertility is generally attributed to a complex of factors related to the process of modernization, economic development and industrialization, but attempts to identify these factors precisely and to organize them into a systematic classificatory scheme have not proved very satisfactory. The fundamental, underlying factors most frequently proposed (such as urbanization, improved levels of education, social mobility and declining mortality) are admittedly overlapping and heterogeneous. Furthermore, agreement is lacking as to the relative importance of each of these underlying factors and their mode of interaction with each other as variables influencing the level of fertility.

79. The absence of a systematic theory of the determinants of fertility in terms of which relevant data can be accumulated is generally recognized. One of the authors of the Indianapolis Study has admitted that "one of the weaknesses [of the study] was that the twenty-three hypotheses set up for testing were not bound together by any organizing theory".<sup>182</sup> A Steering Committee on the Development of Plans for New Studies in Fertility formed in the United States in 1953, was unable, after a year of intensive work, to develop an acceptable theoretical framework which could integrate the hypotheses of future fertility surveys.<sup>183</sup> Similarly, the absence of "systematized theoretical generalizations" in the analysis of factors affecting fertility and the resulting practice of giving equal weight to all factors ("the eclectic theory of 'equal factors'") has been deplored by Kozlov.<sup>184</sup>

80. It is possible to distinguish two principal approaches which have been employed to investigate the transitional decline from high to low fertility. The first of these approaches, that of *differential fertility*,<sup>185</sup> is based on the observation that the decline from previously high levels of fertility did not usually proceed uniformly among all sectors of a population. It identifies and investigates characteristics which differentiate those sectors of the population which were in the vanguard of the secular change in fertility, the assumption being that these groups experienced differential exposure to the effects of the underlying determining factors. The second

approach studies the whole vast range of changes in the social and economic organization of society that appear to have been associated with economic development, in order to select those changes which can most plausibly be said to have affected fertility trends.

81. Both these approaches, unfortunately, have produced very limited results, largely due to the unavailability of the requisite data covering the period just prior to and during the first stages of declining fertility. The differential fertility approach, quantitative and inductive in nature, has perforce been obliged to restrict its analysis to available data (usually population census-type characteristics<sup>186</sup> such as urban-rural residence, level of education and occupation) not pin-pointed towards and for the most part only indirectly related to the study of fertility. The resulting differentials have been put to various uses: some analysts have treated the differential characteristics as causal factors in the decline in fertility; others have employed them as indices or indicators of the true but unknown factors;<sup>187</sup> others have fastened their attention on the socio-economic status differentials and have formulated the "cultural lag" theory according to which "... the decline in family size began among the well-to-do, the urban and the educated [who] were the first to adopt the rational attitudes towards fertility needed to utilize the means of fertility control ... The poorer, the less-urbanized, and less-educated elements of the population followed this lead, but apparently after a considerable time lag";<sup>188</sup> others, recognizing that the cultural lag theory is more a description of *how* the decline occurred, than an explanation of *why* it occurred, have attempted to supplement it by establishing a relationship between each differential characteristic and the explanatory factors obtained through the second approach.<sup>189</sup>

82. The second approach, essentially deductive in its search for hypothetical factors affecting fertility, has been forced to limit itself mostly to qualitative and speculative analysis in the absence of relevant data. It has yielded a rich harvest of convincingly plausible hypotheses whose validity can rarely be verified with any degree of precision. The themes which recur most frequently generally relate to the economic and social changes which transformed

<sup>186</sup> See, for example, Ryder, "Fertility" (1959), pp. 413-414. This kind of information, supplemented by a wide range of social and psychological characteristics of household members, continues to be collected in the KAP fertility surveys that began with the Indianapolis Study shortly before the outbreak of the Second World War. Various demographers have commented on the limited usefulness of data of this kind for the purpose of understanding the fundamental factors affecting fertility trends. According to Davis, field surveys "cannot substitute for historical and statistical studies encompassing long-run changes" because they suffer from the inevitable limitation of covering only a brief time period and produce a strong "tendency to psychologize and thus overlook sociological determinants of reproduction ..." [Davis, "The sociology of demographic behavior" (1959), pp. 319-323]. In the opinion of Jaffe, "no study dealing only (or almost exclusively) with the individual and his immediate family will be very productive of findings". [Jaffe, "Book review of *Social and psychological factors affecting fertility*, vol. 5" (1960), p. 167.]

the functions of the family and children during the transition from pre-industrial to urban-industrial society.<sup>190</sup>

83. Although there are wide variations in concept and terminology which affect different authors' presentation of the fundamental, underlying factors relating to the economic and social structure, a tendency has been emerging to identify, in between the intermediate variables affecting fertility and the fundamental factors, another group of variables referring to attitudes and motivations towards fertility. These variables are frequently designated the cultural factors affecting fertility. Among the economic and social factors themselves, special emphasis is usually given to the family and its changing functions and structure as a variable influenced by the other underlying economic and social factors, which in turn affects the cultural factors.

## 1. CULTURAL FACTORS

84. The term culture is used in a variety of senses, by demographers, sociologists and anthropologists.<sup>191</sup> Cultural factors affecting fertility are intended here to refer broadly to all motivational aspects of reproductive behaviour, although principally to the institutionalized norms and values of a society by which individuals are guided in their actions relating to the number of children they have. Included, for example, are the "social norms" concerning family size and each of the intermediate variables which Freedman analyses in his discussion of the Davis and Blake framework.<sup>192</sup> These social norms are similar to Kozlov's "complex of ideological factors" which he describes as having been formed around the institution of the large family and which found their support in "public opinion, moral canons, the rules of marriage and, lastly, the precepts of religion, which, of course, did not create the tradition but only strengthened established national customs".<sup>193</sup> Lorimer has defined the term "cultural values" as referring to "attitudes and interests which are, in part, engendered by a particular social structure and which in turn motivate and direct the activities of the individuals who form a society".<sup>194</sup>

85. The concept of cultural factors has here been widened to encompass the information from recent fertility surveys on individual attitudes towards family size and reproductive practices.<sup>195</sup> The relationship between individual values and attitudes on the one hand and social norms on the other hand is not yet well understood. "Empirical studies of social norms or values about

family size are . . . mainly a postwar product of sample surveys",<sup>196</sup> and "there is a serious lack of knowledge of the circumstances under which an apparent consensus about fertility in a population . . . really has normative force in directing what behavior ought to be in the society".<sup>197</sup>

86. Religious teachings relating to fertility are thought by many to lend important support to traditional large family values. It is also often assumed that a decline of religious interest has been conducive to the limitation of family size. Inferred is the notion that religious interest has declined as traditional values have given way to rationalist modes of thinking. Thus, the control of family size is believed to lie less within the jurisdiction of religious institutions and increasingly within the domain of the family itself.<sup>198</sup>

87. Certain attempts have been made to measure the association between attitudes towards religion and fertility, since changed attitudes, to a greater extent than a decline in institutional affiliation, are believed to be associated with the decline in family size. In France the patterns of fertility of various regions with differences in the attitude of the population towards the Catholic Church have been studied. In departments where attachment to religion was strong, fertility was in general above the average. However, this study failed to establish that the decline in fertility for the period 1860-1935 was associated with adherence to religion.<sup>199</sup>

88. There has been much discussion as to how much and what kinds of changes are required in pre-industrial areas in order that motivation in favour of small families may develop.<sup>200</sup> Many writers believe that the decline of fertility in European society involved profound changes in motivation.<sup>201</sup> However, because of the paucity of data relating to the decline of fertility in those countries where fertility has already fallen to low or moderate levels,<sup>202</sup> views about how much of a modification in motivation occurred are of necessity largely conjectural and based on indirect inferences from such sources as the meagre data on the kinds of family limitation methods that were used.<sup>203</sup>

89. In the United Kingdom, the modern movement of family limitation did not begin until the last quarter of the nineteenth century, although there is evidence that a latent desire for smaller families existed before that time. It was only under the cumulative impact of "... the

<sup>190</sup> See, for example Sauvy, *Théorie générale de la population* . . . (1966), vol. 2, pp. 131-132; United Kingdom, Royal Commission on Population, *Report* (1949), pp. 38-44; Coale, "Factors associated . . ." (1967), p. 208.

<sup>191</sup> For a review and critique of existing definitions of culture, see Jaeger and Selznick, "A normative theory of culture" (1964).

<sup>192</sup> Freedman, "The sociology of human fertility . . ." (1961/62), p. 39.

<sup>193</sup> Kozlov, "Some causes of the high fertility . . ." (1967), p. 158.

<sup>194</sup> Lorimer, *Culture and Human Fertility* . . . (1954), p. 198.

<sup>195</sup> As Davis has pointed out, this kind of information is frequently thought of as cultural even when, as sometimes happens, investigators fail to relate these values to their institutional setting in the social structure. [Davis, "The sociology of demographic behavior" (1959), p. 322.]

<sup>203</sup> Coale, "The voluntary control . . ." (1967), p. 168; Sauvy, *Théorie générale de la population* . . . (1966), vol. 2, p. 225.

profound [social and economic] changes that were taking place in the outlook and ways of living of the people . . .", however, that the psychological barriers to birth control were broken down. The move towards family planning received a powerful impetus from the publicity surrounding the trials of Bradlaugh-Besant in 1877-1888 for spreading birth control propaganda, as well as from improvements in contraceptive methods.<sup>204</sup>

90. The importance of motivation for the successful practice of family limitation is stressed by Sauvy, who distinguishes three stages through which couples pass in their attitude with regard to having children: "(a) positive desire to have many children, (b) positive desire for a limited number of children, but absence or insufficiency of positive motivation requisite for satisfying this desire, (c) positive motivation sufficiently strong to limit the number of children".<sup>205</sup>

91. The motivational factor is not always taken into consideration in writings on factors affecting past declines in fertility. Sometimes it is merely stated that the population responded to the underlying social and economic factors, or that changes in the social and economic factors "... are followed by conscious efforts on the part of parents themselves to regulate the size of their families",<sup>206</sup> without indicating whether a change in motivation was involved. One demographer who specifically affirms his opinion that the change in motivation was relatively small in the change-over from high to low fertility defends his view on the basis of changes in the structure and functions of the family.<sup>207</sup>

## 2. ECONOMIC AND SOCIAL FACTORS

92. As was explained earlier, any selection of underlying factors affecting fertility trends is necessarily of an arbitrary nature and in this respect reflects the lack of agreement and even confusion found in the literature. The economic and social factors selected for review here are as follows: (a) family functions and structure, (b) relationship between mortality and fertility, (c) rising levels of living and increased costs of children's upbringing, (d) levels of education, (e) social mobility, (f) urbanization, and (g) industrialization.

93. It must be stressed that a whole complex of interacting factors is responsible for the change from high to low fertility, and attempts to associate the decline exclusively with a particular factor have not proved satisfactory. As Coale points out, "Fertility fell in Spain, Bulgaria and other Southern and Eastern European countries when mortality was still very high; in many countries rural fertility declined as early and as much as urban fertility; in some countries industrialization was far advanced before marital fertility fell, in others a major decline preceded substantial industrialization . . . In European national experience, the only factor appar-

ently always changing at the same time that fertility declined was literacy, but the onset of fertility decline has no consistent relationship with the proportion literate at the time."<sup>208</sup>

### (a) Family functions and structure

94. Many authors who have written on the social and economic factors responsible for the transitional decline of fertility either implicitly or explicitly attribute to the family, because of its unique social role in the bearing and raising of children, special significance apart from that of the other factors relating to social structure.<sup>209</sup> In a variety of ways, changes in society at large wrought changes in the structure and functions of the family, making the large family a liability rather than an asset.

95. With growing urbanization and industrialization, the family by and large lost its function as an economic unit; this, together with the enactment of child labour laws and the extension of compulsory education, drastically modified the economic usefulness of children to parents as a source of cheap manpower. At the same time, new extra-familial roles for both husband and wife began to compete with the traditionally-defined parental roles. In an increasingly impersonal society, the family emerged as one of the few loci for personal affective relations. As the father of the family lost his traditional authority and with the growing emancipation of women, the companionate aspect of marriage became emphasized over the reproductive aspect and the parent-child relationship shifted from one of exploitation in quantity to that of cultivation in quality.<sup>210</sup> At a time when the costs of child-rearing were becoming ever more burdensome, average family size was also increasing as a result of declining mortality.

96. The nuclear family was highly sensitive to these new conditions, as it alone had to bear full responsibility for the care and maintenance of increasing numbers of surviving children for longer periods of time. But not only did the structure of the European family facilitate the relatively prompt perception of family interests under the altered conditions of living; it also permitted the ensuing widespread, spontaneous response in the form of modified reproductive behaviour.<sup>211</sup> In societies with a different family structure, such as those of many of

<sup>208</sup> Coale, "Factors associated . . ." (1967), p. 208.

<sup>209</sup> Lorimer, *Culture and Human Fertility* . . . (1954); United Kingdom, Royal Commission on Population, *Report* (1949), pp. 38-41; Sauvy, *Théorie générale de la population* . . . (1966), vol. 2, pp. 185-186; Breznik, "Female fertility in industrialized . . ." (1967), p. 197; Freedman, "The sociology of human fertility . . ." (1961/62), p. 56.

<sup>210</sup> Sauvy points to the development of "puericulture" (i.e., the art or science of rearing and educating children) during the fertility decline in France as evidence of the increased value and importance of the individual child. [Sauvy, *Théorie générale de la population* . . . (1966), vol. 2, pp. 131, 229.] According to Ariès, there took place around the seventeenth century "... a major transformation of the family: the latter fell back upon the child, and its life became identified with the increasingly sentimental relationship between parents and children". [Ariès, *Centuries of Childhood* . . . (1962), p. 370.]

<sup>211</sup> Lorimer, *Culture and Human Fertility* . . . (1954), pp. 201-202, 248-251; Ryder, "The character of modern fertility" (1967).

the high-fertility countries of today, large family norms are slower to respond to changes in the underlying social structure (see section E below).

(b) *Relationship between mortality and fertility*

97. As discussed elsewhere in this chapter, high fertility has frequently been a response to high mortality. The decline in mortality in industrialized countries, particularly among infants and young children, was an important element in creating an atmosphere favourable to the development of family limitation.<sup>212</sup> As mortality declined, the pressures of an increased number of surviving children on limited familial resources made themselves felt. Instead of having extra births in order to assure the survival to adulthood of the desired number of offspring, a tendency was noted for parents to "replace" a child who had died.<sup>213</sup> Under the continued impact of greatly reduced mortality, women have become increasingly aware that "... in the present fundamentally new conditions of population replacement a woman may give birth to fewer children yet retain as many as survived in the not too distant past ...".<sup>214</sup>

98. The decline in mortality among adults has also been suggested as a factor promoting family limitation. Thus, the slower elimination of the aged from the labour force is said to have made the economic situation more difficult for those in the reproductive ages.<sup>215</sup> Further, the dependency burden may have increased because of the greater survival of the aged and thereby have encouraged smaller families.<sup>216</sup>

(c) *Rising levels of living and increasing costs of children's upbringing*

99. During the period of declining fertility, average real income was rising, and the rich generally had fewer children than the poor. With increasing income, the rational planning for one's future and that of one's children became possible, and increasing wealth might therefore logically lead to decreases in fertility. It has been pointed out that there is no simple relationship between income levels and fertility levels, and that, following the decline of fertility among the rich, the decline also spread to the poorer groups. This was particularly true in large cities, where marked decreases in fertility occurred among the relatively poor.<sup>217</sup>

<sup>212</sup> In France, however, the infant mortality reduction could not have been responsible for the initial spread of family limitation because the decline of the death and birth rates occurred at the same time. Landry, *La révolution démographique* ... (1934), p. 38.

<sup>213</sup> Geissler, "Über den Einfluss der Säuglingssterblichkeit ..." (1885), p. 23; Sanders, *The Declining Birthrate in Rotterdam* (1931), chap. 9; Verrijn-Stuart, "Natalité, mortinatalité et mortalité ..." (1902), p. 368.

<sup>214</sup> Davytan, "The influence of socio-economic factors ..." (1967), p. 77.

<sup>215</sup> Ungern-Sternberg and Schubnell, *Grundriss der Bevölkerungswissenschaft* (1950), pp. 282-283.

<sup>216</sup> Winkler, "Der Geburtenrückgang, seine Ursachen ..." (1938), p. 17.

<sup>217</sup> These arguments were used in the controversy in the German literature about the extent to which "wealth" should be regarded as the cause of declining fertility. The importance of wealth was stressed by Brentano, "Die Malthussche Lehre ..." (1909), pp. 603-606; and Mombert, *Studien zur Bevölkerungsbewegung* ... (1907), chap. 3. On the other side Oldenberg, ["Über den Rückgang ..."]

100. The increasing costs of rearing children have been widely stressed as a factor in fertility decline. By the second half of the nineteenth century, it became questionable whether children were economic assets.<sup>218</sup> With the abolition of child labour and the enactment of compulsory education laws, children ceased to be a source of income for their parents and instead required increasing expenditure for education, thus threatening a reduction of living standards.<sup>219</sup>

101. At the same time, the State has been assuming, in increasing measure, certain financial responsibilities previously borne by the family, e.g. the cost of medical care. This trend serves to mitigate the depressing effect on the family's standard of living resulting from additional offspring.<sup>220</sup>

102. In recent years several attempts have been made to develop economic or socio-economic theories to explain household decisions concerning family size. Becker proposed a model based on conventional economic theory of consumer behaviour, according to which children were considered as a kind of commodity, and household decisions concerning the number of children desired were determined by weighing preferences against the constraints of income and costs. According to this theory, parents compare the utility of children with that derived from other goods; if knowledge of birth control methods was universal, fertility would be positively associated with income.<sup>221</sup> Various comments and criticisms have been made of Becker's model.<sup>222</sup> Easterlin, for example, suggested modifications of the concepts of income, prices, taste preferences and fertility control to emphasize the influence of sociological factors acting as constraints on economic factors. He proposed a more complex treatment of the factor of birth control practice in the model to take account of differing attitudes among various socio-economic groups.<sup>223</sup>

(1911)], Wolf [*Die neue Sexualmoral* ... (1928), pp. 37-40], and others stressed the complexity of the relationship between income and fertility. In France the role of wealth has been stressed particularly by Bertillon, *La dépopulation de la France* (1911), pp. 110 ff., although he by no means regarded it as the exclusive cause of the decline.

<sup>218</sup> Glass, *Population Policies and Movements in Europe* (1940), p. 58.

<sup>219</sup> Billig, *O prawach rozwoju ludności* (1963). Recent surveys have mentioned financial costs as reasons for not having larger families. See, for example, Prokopec, "Vdana žena v rodine a zamestnani -1961" (1963); Sveton and Vávra, *Reprodukcia obyvateľstva Československa* ... (1965).

<sup>220</sup> For example, a study in Great Britain showed that, despite rising costs, the added financial burden imposed by a second child was less in 1948 than in 1938, owing to subsidies provided by the State. Henderson, "The cost of children" (1950), part 2, pp. 295-298. In the Soviet Union, it is anticipated that by 1980 as much as 75-80 per cent of the cost of maintenance of children will be provided from public funds. Uralis, "Dynamics of the birth rate ..." (1967), p. 235.

<sup>222</sup> For different views and comments see, for example, Blake, "Are babies consumer durables?" (1968); Spengler, "The economist and the population question" (1966).

<sup>223</sup> Easterlin, "Towards a socioeconomic theory ..." (1969). For other modifications see Mincer, "Market prices ..." (1963); Namboodiri, "Some observations ..." (1972). See also Espenshade, "The price of children ..." (1972) and Freedman, "The relation of economic status ..." (1963).

#### (d) Levels of education

103. A generally inverse relationship between fertility and educational level appears to have existed in the United States and various European countries since the late nineteenth century, although this relationship is now diminishing or even disappearing in some low-fertility countries (see section F below). Moreover, it has been pointed out above (para. 93) that an increase in literacy has always taken place simultaneously with a reduction in fertility. The increased education of women in particular has frequently been mentioned as an important contributing factor to the changing attitude among women to their traditional role as homemaker and bearer of children, and related to this changing attitude is the greater degree of participation of women in gainful employment, believed by some writers to be an alternative for women to the bearing and rearing of children. Some Russian writers stress that access of Soviet women "to education and to literature, art, science and political activity" has been the most important of the social factors contributing to the reduction of fertility in the USSR.<sup>224</sup>

#### (e) Social mobility

104. The desire to improve one's position in the social scale has been stressed as an important motive for family limitation. The argument is particularly associated with the name of Dumont, who in the latter half of the nineteenth century devoted an extensive series of studies to this phenomenon, which he termed "social capillarity" (*capillarité sociale*). (See also chapter III, section F.) Just as a column of liquid must be thin in order to rise under the force of capillarity, so also must a family be small to rise in the social scale.<sup>225</sup> He and many others have argued that during the period when family size declined, the mobility between social classes increased greatly, and new attitudes toward social mobility developed. Whereas formerly most men took their social position for granted, concern with improving one's own position or that of one's children became an ever-pressing preoccupation. The recognition that rearing children absorbs money, time and effort which could otherwise be used to rise in the social scale fostered motivation for smaller families.<sup>226</sup> When people are maintained at the subsistence level with little hope for improving their social status, such incentives are lacking.<sup>227</sup>

105. Using various measures of socio-economic status, such as occupation, income of head of household or of

family, and rental value of the dwelling unit, many writers have found a clear inverse relationship between socio-economic status and fertility. These cross-sectional studies, the findings of which are reported in section F below, lend weight to the accepted inference that changes in the class structure of Western societies have played an important part in the secular decline of fertility. For example, while there has been a tendency for fertility to decline among all occupational groups, the shifting occupational pattern away from primary industries characterized by high fertility, toward white-collar and skilled industrial occupations characterized by lower fertility, is in itself a factor tending to depress fertility.

106. Although quantitative data on the relation between social mobility and fertility are not available for the period of major fertility decline, contemporary studies which examine this relation may contribute to an understanding of past processes. Such studies examine fertility performance in relation to the changes in the individual's status throughout his working life, or to changes in status from one generation to the next. Berent examined both aspects in his analysis of data from a sample survey of England and Wales in 1949. He found that upward mobility (based on a comparison of father's and son's social class) was associated with lower fertility, while downward mobility was associated with higher fertility. Moreover, those who moved to a higher social class between the time of marriage and time of interview had on average smaller families than those who remained static.<sup>228</sup> Some French and Hungarian studies have also suggested that there is a relationship between social mobility and family size.<sup>229</sup>

107. The findings have been more problematic in recent studies in the United States directly concerned with the relation of social mobility and fertility. Analyses of data from the Indianapolis Study showed that couples who experienced intergenerational upward mobility tended to come from smaller families than non-mobile couples,<sup>230</sup> but the relationship between fertility and mobility after marriage was much less clear.<sup>231</sup> Goldberg,

<sup>224</sup> Berent, "Fertility and social mobility" (1952).

<sup>225</sup> In a 1948 sample survey in France, it was found that the proportion of persons who had advanced in social class was higher among small families than among large families. Bresard, "Mobilité sociale et dimension de la famille" (1950), p. 563. Analyses of the family background of students at boys' *lycées* and law schools showed that students from higher social strata came from larger families than those of more modest social class, the inference being that in the latter class only small-sized families were able to provide secondary or higher education for their children. Girard, "Mobilité sociale et dimension de la famille, 2ème partie . . ." (1951). In Hungary, a 1962 sample survey of Budapest found upward mobility to be associated with lower fertility. The average number of children of manual workers who had moved to intellectual occupations was even lower than that of intellectual workers who had not moved upward from lower strata. Szabady, "Socio-occupational stratification . . ." (1964), p. 163.

<sup>226</sup> Kantner and Kiser, "Social and psychological factors affecting fertility, xxii . . ." (1954); Riemer and Kiser, "Social and psychological factors affecting fertility, xxiii . . ." (1954).

<sup>227</sup> Riemer and Kiser, "Social and psychological factors affecting fertility, xxiii . . ." (1954). Although little support was given to the hypothesis that low fertility is closely related to increasing income during marriage, some association was found between upward occupational mobility of husband and lower fertility, as measured by the average number of living children.

<sup>224</sup> The words quoted are from Ulanis, "Dynamics of the birth rate . . ." (1967), p. 235. See also his *Rozhdaemost i prodolzhitel'nost zhizni v SSSR* (1963).

<sup>225</sup> Dumont, *Dépopulation et civilisation* (1890), pp. 106 ff.; and his *Natalité et démocratie* (1898), pp. 163-186, 190-191, 212-226.

<sup>226</sup> United Kingdom, Royal Commission on Population, *Report* (1949), pp. 38-44; George, *Introduction à l'étude géographique . . .* (1951), p. 217.

<sup>227</sup> See Mombert, *Studien zur Bevölkerungsbewegung . . .* (1907), pp. 168 ff.; and his *Bevölkerungslehre* (1929), pp. 314-316. It has been suggested that the early decline of the birth rate in France was related to the special conditions existing in that country in the eighteenth century. Thus, "social promotion was not so difficult that all ambition was stifled; it was not so easy that unlimited fertility did not constitute a serious handicap in the struggle to rise in the social scale". Blacker, "Social ambitions of the bourgeoisie . . ." (1957), p. 63.

on the other hand, found little relation between inter-generational occupational mobility and completed family size in his analysis of sample survey data for indigenous urban women in Detroit.<sup>232</sup> More recently, a study of a sample of women in metropolitan areas suggested that upward social mobility, as measured by changes in income, might be weakly associated with an orientation toward smaller families.<sup>233</sup> In the words of Freedman: "The American findings may indicate what happens in a society when mobility becomes so predictable and routine as to minimize its social and monetary costs and when the goal of the mobility is a life style which includes a moderate number of children. The fertility level of the whole society may be affected by a dominant high valuation of mobility, even if mobility differences within the society do not lead to internal fertility differentials. In a society with high mobility even the non-mobile may limit family size simply to maintain their place in the social order."<sup>234</sup>

#### (f) Urbanization

108. Students of urban development in the past have associated certain aspects of the urban environment with relatively low fertility. Park, Wirth and Redfield in turn maintained that secularization, secondary group association, increased segmentation of roles and poorly defined norms characterize urbanism as a way of life and make for lower fertility among the urban community.<sup>235</sup> More recently, other writers have suggested that such views stress unduly the secularization and disorganizational aspects of urban life.<sup>236</sup> Nevertheless it seems safe to conclude that the urban environment in the long run has been conducive to the reduction of human fertility, although in the early stages of urbanization, there is evidence of higher urban than rural fertility in certain areas.<sup>237</sup> In Western Europe and Northern America there was evidence of lower urban than rural fertility as early as the seventeenth and eighteenth centuries.<sup>238</sup> In some countries it seems that rural and urban fertility declined equally fast in the nineteenth century, while in others the

difference between town and country widened, because urban fertility at first declined more rapidly.

109. The idea that it is the "urban mentality" rather than mere residence in cities which is responsible for declining family size has been advanced by some writers as an explanation of the earlier decline in fertility in France as compared with England, although the proportion of population living in cities was much higher in England than in France. It has been suggested that, because France was more unified than England, the relationship between the people of the cities and the countryside was closer in France than in England. Thus, workers moving to English cities required more time to adjust to urban life. In England, also, a child was an economic advantage to its parents as a result of the "poor laws" and child labour. For these and other reasons, those aspects of an urban mentality which reduce fertility are believed to have spread less rapidly in England than in France. Similar reasons are given to explain why the German birth rate remained high for some time following the rapid movement of population to cities.<sup>239</sup>

#### (g) Industrialization

110. The fact that the industrialization of Western Europe and Northern America has been accompanied by a sequence of demographic changes has led many writers to conclude that industrialization has played a dominant role in past fertility declines and that populations with high fertility will experience similar declines as they come under the sway of industrialization.<sup>240</sup> Industrialization, by virtue of its comprehensiveness, in a sense encompasses all the economic and social factors reviewed above. The scientific and technological aspects of industrialization have been accompanied by substantial modifications of manpower requirements in terms of ever-rising levels of skill and this in turn has contributed to the higher levels of education and to the increased cost of raising children. Scientific and technological developments have also been largely responsible for the decline of mortality, which has often been a precondition for fertility decline in many of the industrialized countries, and the first link in the chain of demographic events known as the demographic transition.<sup>241</sup>

111. The relationship between industrialization and some of the economic and social factors associated with fertility decline has been summarized by Freedman as follows: "industrial urbanization was associated with a much more complex division of labor in all spheres of life; together with the associated high rate of social and physical mobility, this inevitably led to a growth of secularism and rationalism, the declining influence of such traditional forces as religious faith, the shattering

<sup>232</sup> Goldberg, "The fertility of two-generation urbanities" (1959), p. 219.

<sup>233</sup> Westoff *et al.*, *Family Growth in Metropolitan America* (1961), p. 247.

<sup>235</sup> Park, "The urban community as a spatial pattern . . ." (1926); Wirth, "Urbanism as a way of life" (1938), particularly pp. 20-21; Redfield, *The Folk Culture of Yucatan* (1941), pp. 187-228.

<sup>236</sup> Sjöberg, "Comparative urban sociology" (1959), pp. 341-344; Freedman, "The sociology of human fertility . . ." (1961/62), p. 57.

<sup>237</sup> Ariès, *Histoire des populations françaises . . .* (1948), pp. 368-369. Ariès argued that the sudden uprooting of the proletarian masses, who streamed into the cities, may even have arrested or reversed an established trend towards family limitation. The causes which brought about the reduction of fertility of the proletariat in large cities—a fertility originally higher than the countryside—are also discussed by Heberle, "Social factors in birth control" (1941).

<sup>238</sup> For example, in the ratio of children to women of child-bearing age the difference between agricultural and industrial states was already marked at the 1800 census of the United States. Whelpton, "Industrial development and population growth" (1928), p. 462. See also Jaffe, "Urbanization and fertility" (1942), pp. 55-57.

<sup>239</sup> Halbwachs, "Réflexions sur un équilibre démographique" (1946), pp. 299-300.

<sup>240</sup> Notestein, "The economics of population . . ." (1953), pp. 15-21; Davis, *Human Society* (1949), pp. 600-608, 615-616.

<sup>241</sup> According to demographic transition theory, the transition from high to low fertility is initiated by declining mortality followed by rapid population growth and the breakdown of traditional practices relating to fertility and to family size (see chapter III above for a fuller discussion).

of traditional family and other primary group associations, the growth of either economic individualism or the attachment of the individual to a large, impersonal, specialized organization".<sup>242</sup>

### E. Factors related to levels and trends of fertility in high-fertility areas

112. In studying the factors responsible for high fertility, demographers have found it fruitful to compare economic, social and cultural conditions between high-fertility countries and countries where fertility is now low.<sup>243</sup> In this way the relationship of fertility levels to specific economic, social and cultural variables can be investigated. As will be seen below, this approach has led to the hypothesis that for the most part the same factors which are thought to account for the decline of fertility in the low-fertility countries are, in a reverse sense, also responsible for the continued high levels of fertility in the high-fertility group. Fertility has failed to decline either because at least some of the variables have not yet changed sufficiently to produce a modification of reproductive behaviour or because they have evolved differently than in the low-fertility countries.

113. Although the factors studied in this section are essentially the same as in the previous one, it has seemed appropriate to structure the discussion differently. In conformity with some of the important research that has been done linking the cultural factors (i.e., norms, attitudes, motivations) with the structure and function of the family, these two sets of factors are reviewed simultaneously. For similar reasons, the economic, social and other factors, treated separately in the last section, have been grouped together as the complex of interrelated threshold factors which they are widely believed to be.

#### 1. CULTURAL FACTORS AND FACTORS RELATED TO FAMILY STRUCTURE AND FUNCTION

114. Two very general explanations are usually offered for high fertility in the less developed areas. "From either the individual or the social point of view, high fertility has been an adjustment both to high and variable mortality and to the central importance in community life of familial and kinship ties. In most pre-industrial societies a wide range of activities involve interdependence with kinsmen and especially with children. These include production, consumption, leisure activity, assistance in illness and old age and many other activities covered by non-familial institutions in modern societies. To simplify greatly: large numbers of children are desired if the values considered worthwhile are obtained through familial ties rather than through other social institutions. If kinship ties are very important in a society where mortality is high and variable, the number of births desired and produced will be especially high in order to insure the

survival to adulthood of the essential minimum number of children."<sup>244</sup>

115. In societies where the kinship group must fulfil a multiplicity of functions, the basis of social organization is often a corporate kinship system with emphasis on unilineal descent, whether patrilineal or matrilineal. Such kinship systems generally provide strong motivation for high fertility; numerous children are valued as contributing to the strength of the group, economically as well as militarily, and of ensuring its continued survival.<sup>245</sup> Where the nuclear family is subordinate to a wider kinship group, the burdens of parenthood are eased by the co-operation of other members of the household in caring for the young and sharing in the economic costs. Under such kinship systems, the compulsion to marry is strong. The unmarried female may be a liability for her family, while, from the standpoint of the male, marriage means at once a link with another strong family and a means of expanding his own agnatic line.<sup>246</sup>

116. Tambiah and Ryan, studying familial institutions in Ceylon, have identified certain family values which are "close to the ideological core within which this people's high fertility mores are enmeshed". One of the main values inherent in the peasant family system is kinship or the blood relationship forming a continuous link between persons. The lineal family stands above the individual; family members are expected to devote themselves to maintaining family honour and prosperity. The selection of the partner for a child is the responsibility of the parent. So far as childbearing is concerned, a large number of children contributes to the strength and prosperity of the family. Sons perpetuate the family name. Daughters, although of less importance, may also raise the family fortunes through hypergamic marriage. The limitation of family size is contrary to family mores; and fertility is an important attribute of the female. Although the female is in an inferior position to the male, as a mother she holds a commanding position and in this role is held in high esteem by her children.<sup>247</sup>

117. While it has often been argued that the extended family system is favourable to high fertility, there have been few empirical studies which attempt to assess the effects on fertility of various forms of familial organization in high-fertility societies. Several studies conducted in rural India, however, revealed that women living in nuclear families generally had somewhat higher fertility than those living in joint families, lower frequency of coitus among the latter group being possibly a contributory factor.<sup>248</sup> The Indian data were limited in scope, but even if the results prove to be more widely true among

<sup>244</sup> Freedman, "Norms for family size . . ." (1963), pp. 226-227.

<sup>242</sup> Freedman, "The sociology of human fertility . . ." (1961/62), p. 56.

<sup>243</sup> Freedman, "Fertility; statement by the Moderator" (1966), p. 37.

populations in which birth control methods are little known, it is nevertheless quite possible that, once the modernization process began to take hold, the greater pressures on parents in nuclear families would lead them to a more rapid adoption of contraception.

118. In many pre-industrial societies there is considerable emphasis on the procreation of male children, in order to perpetuate the family line or to perform certain religious rites. Thus Hindu tradition demands that every family should have a son.<sup>249</sup> A recent survey of male attitudes towards family limitation in East Pakistan revealed that those males who wanted more children in fact, for the most part, really desired more sons for security in their old age, daughters being regarded by some as burdensome and costly.<sup>250</sup> The old Chinese proverb "one son is no son, two sons are an undependable son, and only three sons can be counted as a real son"<sup>251</sup> and the traditional wish addressed to an Indian bride, "Be the mother of eight sons!"<sup>252</sup> are symptomatic of the need for many extra births in order to maintain family size at an accepted level. In high-mortality societies generally, the felt need to ensure at least one surviving son is likely to imply a desired family size of at least four children and possibly more.<sup>253</sup>

119. It has been noted that large-family values tend to persist after the disappearance of the economic and social conditions responsible for them. According to Kozlov, "the complex of ideological factors which formed around the institution of the large family [became] relatively independent of the material factors which gave rise to it. As a result, the tradition of large families continues to exist even when the basic material factor underlying it—a high death rate—has ceased or is ceasing to be operative";<sup>254</sup> for Lorimer, "cultural inertia" which hampers "any rational adjustment of reproductive patterns to objective conditions . . . is the most powerful obstacle in the modern world to the rational ordering of personal behaviour influencing population trends".<sup>255</sup>

120. In many developing countries religion may have helped to sustain high fertility, although the absence of direct prohibitions against methods of family limitation other than abortion in religions such as Hinduism, Buddhism and Islam has been pointed out. In dealing with the attitudes of major religions to fertility, analysis must take into account "the beliefs and practices of the living community as well as the tenets advanced on the basis of sacred writings and traditions. It is often assumed that differences between the two mean a dilution of faith and the supervention of non-religious influences. Any such assumption should be tested, for in the application of religious principles to changing social conditions it is

quite normal to find a certain interaction, a kind of dialogue, between the community of believers and the religious heritage expounded by the teaching authorities".<sup>256</sup>

121. Some writers have taken the view that Roman Catholicism, with its strong condemnation of contraceptive devices, has tended to consolidate high fertility mores and has been a powerful factor upholding large family norms in Latin America and the Philippines. Day, however, suggests that Catholicism is not the key factor involved, but that populations currently experiencing high fertility will reduce their fertility when, and only when, their other conditions of life are conducive to it, and they will do so regardless of any church's opposition.<sup>257</sup> The Roman Catholic Church has in any case gradually modified its attitude to the procreative duty of married couples, and the concept of a prudent regulation of fertility, using approved methods, has offset to some extent the Church's pro-natalist position.<sup>258</sup>

122. Some writers believe that Moslem populations may offer a more prolonged resistance to fertility decline than other religious groups. Among the reasons they cite are the following: (a) while Moslem religious doctrine does not specifically prohibit voluntary birth limitation, the institutional pressures to have many children, especially sons, are strong; (b) the population of almost all Moslem countries consists largely of a culturally conservative peasantry, resistant to modern influences; and (c) although recent progress has been noted, the status of women is perhaps lower among Moslems than among other major religious communities.<sup>259</sup> Experience suggests that an improvement in the status of women may be one of the necessary conditions of fertility decline.

123. In studies of fertility differences among Moslem and non-Moslem groups within several developing countries it has been found that, among populations living in cities, Moslem fertility has been higher than that of non-Moslems. Such differences could not be explained solely by socio-economic factors, and it was suggested that religion appeared to play a role in influencing the speed of transition from high to low fertility. (These studies are cited in section F below.)

124. Neither Hinduism nor Buddhism contains doctrines bearing on family planning in the contemporary sense, and there is enough flexibility in both faiths for reformers to be able to put forward the case for scientific methods of family planning without offending the adherents. Nevertheless, classical Hindu teaching has a strongly pro-natalist orientation. The custom of early marriage and the high incidence of marriage among Hindus, mentioned above, have received support from the stress laid on the begetting of a son to continue the family line. In Buddhist teaching, on the other hand, procreation and family life are matters of secondary

interest, and "... pro-natalist influences in Buddhist cultures appear to stem mainly from folk mores".<sup>260</sup>

125. Studies of attitudes to fertility and family size have been extended in recent years from low-fertility countries to a number of high-fertility countries. Such surveys are indeed an almost essential preliminary to any national plan designed to encourage family limitation. The fertility survey in Mysore undertaken jointly by the United Nations and the Government of India sought spontaneous statements designed to indicate preference regarding family size. Some respondents stressed the economic advantage of children to parents, who can count on the support of their sons and daughters in their old age. Others reported emotional satisfaction gained from large families. It was not only the personal satisfaction felt by parents that mattered, but also the prestige value of a large family in the eyes of friends and neighbours. The fear of losing children was also advanced as a reason for a large family. Some respondents gave what the study calls "irrational" reasons, such as that a person's horoscope decrees that he must have another child.<sup>261</sup>

126. Blake's study of Jamaica shows that, superimposed on the general realization of the pleasures and benefits of parenthood, is an equal awareness of the disadvantages of large families. Thus, on the one hand, children are valued in themselves and for the help they can give their parents with domestic chores, in addition to the family income and in caring for parents in old age. But, it is also recognized that frequent pregnancies constitute a great burden on the female, and that numerous children create difficulties in the way of education.<sup>262</sup>

127. The general findings about family preferences have led writers to conclude that in high-fertility societies, certain segments of the population are receptive to the ideal of small families. Hill, Stycos and Back found that the ideal family size in Puerto Rico was between two and three children, which is about the same average as that obtained earlier by Hatt; these figures are lower than the actual family size.<sup>263</sup> In Chile, women with four children or less expressed a preference for four children, while those with more than four children gave a somewhat higher level of preference, but lower than the actual size of their family.<sup>264</sup> Similar questions in the United Nations Mysore study elicited responses of ideal families averag-

ing between 3.6 and 3.8 among urban married women, and a higher level (4.7) among women in rural areas. These ideal sizes fall considerably short of the actual number of children these women had, and the survey suggests that in many cases the ideal size represents the number of surviving rather than live-born children.<sup>265</sup> Data from a 1962 survey of married women in Taichung City, Taiwan (China) showed a strong preference for a moderate number of children. About 60 per cent of the wives in their thirties wanted between three and four children, while only about 10 per cent wanted at least six. As family size increased, a higher proportion of respondents declared that they had more children than they wanted.<sup>266</sup>

128. The low state of technology and the general unfamiliarity of the population of high-fertility countries with all types of contraception undoubtedly militate against fertility reduction. Nevertheless the evidence now available does not support the view that high-fertility countries would already have adopted family limitation, were it not for the lack of the necessary information and supplies. On the contrary, there is some evidence that large-scale effective use of contraceptives does not by any means automatically follow when they are made available. Furthermore, many observers have expressed the opinion that there is considerable ambivalence about professed small- and moderate-sized family values,<sup>267</sup> and others have commented upon the apparent lack of strong motivation towards the achievement of expressed desires to limit family size.<sup>268</sup> Most scholars agree that some social and economic development is a necessary condition for the widespread adoption of family limitation in high-fertility countries.<sup>269</sup> The social and economic factors are discussed in the following subsection.

<sup>265</sup> United Nations, *The Mysore Population Study ...* (1961), p. 140.

<sup>266</sup> Freedman, Takeshita and Sun, "Fertility and family planning in Taiwan ..." (1964), pp. 18-19.

<sup>267</sup> For example, Hill, Stycos and Back, after an extensive analysis of the consistency of response in their Puerto Rican survey data, conclude that "the expressed preference of so many Puerto Ricans for a moderate sized family probably conceals a great deal of ambivalence ..." [Hill, Stycos and Back, *The Family and Population Control ...* (1959), p. 81]. See also Freedman, "The sociology of human fertility ..." (1961/62), p. 47.

<sup>268</sup> Sauvy and Coale among others have commented upon the high degree of motivation required for the successful use of the classical methods of birth control, and doubt that their use could be mastered by populations which have not yet crossed the critical economic and cultural threshold beyond which the wish to control fertility becomes strong enough to have a significant effect on reproductive behaviour. They point out that, because of the requirement of careful adherence to the calendar, the use-effectiveness of the pill, one of the new and less demanding methods, has sometimes been disappointing in less developed countries. The authors agree that the IUD, on the other hand, requires minimal motivation. [Sauvy, *Théorie générale de la population ...* (1966), vol. 2, pp. 213, 225, 230-231; and his *De Malibus à Mao Tsé-Toung* (1958), pp. 212-215; Coale, "The voluntary control ..." (1967), pp. 166-169.] In line with these views are the findings of Stycos and Back in Jamaica that family size attitudes, although generally favourable to the small family, are characterized by "lack of intensity". [Stycos and Back, *Prospects for Fertility Reduction ...* (1957), pp. 11, 14.]

<sup>269</sup> Freedman, "Fertility; statement by the Moderator" (1966), p. 45.

<sup>260</sup> Fagley, "Doctrines and attitudes ..." (1967), pp. 78-79.

<sup>261</sup> United Nations, *The Mysore Population Study ...* (1961), pp. 145-146. An example of how astrological beliefs may influence fertility behaviour even in a modernized society where fertility is already low is seen in the case of Japan, where the birth rate was temporarily depressed in 1966, "the year of the fiery horse" (which occurs only once in every sixty years), considered to be inauspicious for the birth of girl babies. The crude birth rate declined from 18.6 in 1965 to 13.7 in 1966 and then rose again to 19.3 in 1967. The low crude birth rate in 1966 has been attributed in part to early and late birth registrations, as well as to fewer births. See Biraben, "L'année 'Cheval et Feu'" (1968); and his "Quelques précisions sur l'année 'Cheval et Feu'" (1969).

## 2. ECONOMIC, SOCIAL AND OTHER FACTORS

129. A chapter in a recent United Nations study of fertility is devoted to an examination of the relationships between levels of fertility, as measured by the gross reproduction rate in different countries of both high and low fertility, and the various indicators of the degree of their economic and social development. The twelve indicators chosen for the purpose were income *per capita* energy consumption *per capita*, degree of urbanization, proportion of economically active males employed in non-agricultural activities, hospital beds per 1,000 population, life expectancy, infant mortality rate, proportion of women married (legally or consensually) in the 15-19 age group, female literacy rate, newspaper circulation per 1,000 population, radio receivers per 1,000 population, and cinema attendance. For each of these twelve indicators, the average values of the high-fertility group of countries differ greatly from those of the low-fertility group. Moreover, there is for each indicator a wide gap between the average values for the highest fertility countries in the low-fertility group and the lowest fertility countries in the high-fertility group.<sup>270</sup>

130. Within the high-fertility group, as also within the low-fertility group, the differences in average values of each indicator according to particular levels of fertility are relatively small and of doubtful statistical significance. Nevertheless for the former group, but *not* within the low-fertility group, there does exist some association between fertility and the whole complex of indicators, as can be seen from table IV.9 where the consistency of the

patterns of variation of the indicator averages from one level of fertility to another within the high-fertility group is clear. With few exceptions, the higher the gross reproduction rate, the lower is the average degree of economic and social development as measured by the various indicators. The possible inferences from the data in this table are either that the countries of the very highest fertility are on that account at a disadvantage in development, or that a very low level of development is conducive to exceptionally high fertility.<sup>271</sup>

131. According to the "threshold" hypothesis, improving economic and social conditions are unlikely to have much effect on initially high fertility in a developing country until a certain economic and social level is attained; but once that level is achieved, fertility is likely to enter a decided decline and to be ultimately stabilized at a much lower level.<sup>272</sup> Statistical analysis of the values of the indicators for both high- and low-fertility countries, according to the United Nations report, "brought out some reasons for believing that the levels reached in indicators pertaining to means of communication, health and education may be more pertinent [to the fertility rate] than the levels of the other indicators in this respect. But for any of the indicators, there is obviously nothing immutable about the values that would correspond to such a threshold of declining fertility; these values could be greatly changed under the influence of changing conditions in the world".<sup>273</sup>

132. In this context it is useful to examine the levels of certain economic and social indicators in several countries where recent fertility declines have brought birth rates

<sup>270</sup> United Nations, *Population Bulletin* ... (1965), pp. 134-151. For the results of a multiple correlation analysis of age-specific birth rates, income per head, an index of education, and population density, see Adelman, "An econometric analysis ..." (1963).

TABLE IV.9. UNWEIGHTED AVERAGE OF SOCIAL AND ECONOMIC INDICATORS IN HIGH-FERTILITY COUNTRIES ACCORDING TO LEVEL OF THE GROSS REPRODUCTION RATE

	Range of gross reproduction rate		
	2.00-2.49	2.50-3.09	3.10 and above
Number of countries .....	13	38	34
Economic indicators:			
Income per head (\$US) .....	223	166	154
Energy consumption per head (in equivalent kilograms of coal) .....	486	343	328
Percentage of population in localities of 20,000 or more inhabitants .....	33.0	16.9	12.8
Percentage of economically active males in non-agricultural employment .....	50	39	30
Social indicators:			
Hospital beds (per 1,000 population) .....	4.6	2.7	2.2
Life expectancy at birth (years) .....	46.5	50.8	47.1
Infant mortality (per 1,000 live births) .....	124	104	134
Percentage of women married in 15-19 age group .....	23.5	28.5	29.2
Percentage literate among females 15 years of age and over .....	40.8	31.6	29.5
Newspaper circulation (per 1,000 population per year) ....	56	33	26
Radio receivers (per 1,000 population) .....	42	34	23
Cinema attendance (per person per year) .....	6	4	4

SOURCE: United Nations, *Population Bulletin* ... (1965), tables 9.2, 9.3, and 9.4.

down to the low 30s or below. These countries include China (Taiwan), Singapore, Puerto Rico and Chile (see section A above). Each of these countries can claim some economic and social characteristics which are more common among the low-fertility group of countries than among those of high fertility. In Taiwan infant mortality is lower than in Southern Europe, and the indicators pertaining to education and means of communication are also comparable with those of a number of Southern European countries. Singapore is highly urbanized and a very small proportion of the country's population is employed in agriculture; the income, newspaper circulation, radio receiver and cinema attendance indicators are also relatively high and the infant mortality indicator relatively low. Puerto Rico shows a moderately high level of social and economic development in relation to all twelve indicators, and this is also true of Chile except for the life expectancy, infant mortality and cinema attendance indicators.<sup>274</sup> There is strong evidence which illustrates the widespread desire for family limitation in these four countries.<sup>275</sup>

133. The formulation of the threshold hypothesis reflects the widely shared belief that the same hypothetical economic and social factors reviewed in the previous section as responsible for past reductions of fertility in low-fertility countries have relevance also in explaining fertility levels in high-fertility countries. The combined effect of changes in these economic and social factors, which are overlapping aspects of what is variously referred to as economic and social development, modernization and industrialization, brings about changes in family size norms and in motivation for family limitation. In many of the high-fertility areas of the world this process has not advanced very far, with the consequence that the pre-industrial family structure remains essentially intact and changes in family size motivation are minimal. Children do not become less of an economic asset and more of an economic burden until changes such as the following occur: (a) declining mortality increases family size because a larger proportion of children born survive to adulthood; (b) improved education and new economic opportunities stimulate parental aspirations which conflict with large-family values; (c) extended family ties are weakened as a result of far-reaching social and economic change, thereby increasing the burdens of child-rearing for the nuclear family; and (d) ever-larger segments of the population are exposed to new ideas and influences—for example with respect to leisure-time activities, relations between spouses, parental responsibilities towards children, and birth control methods—which directly or indirectly tend to modify reproductive behaviour.

134. There is much less agreement as to the requisite mixture of the relevant social and economic factors and even as to whether the same combination of factors can be expected to be equally effective in all populations despite cultural variations. It is widely recognized, how-

ever, that many circumstances in the high-fertility countries today are different from what they were before the onset of falling fertility in the low-fertility countries, and the significance of these differences for fertility change is not known. On the one hand are the developments in birth control technology making available at low cost new, mostly female, methods of contraception which require less motivation for effective use than the older methods, and the very knowledge that family planning is a reality in the more advanced countries. On the other hand, rapid urbanization in many developing countries stems more from a rural exodus generated by agricultural overpopulation than from economic expansion and the transformation of industrial and occupational structure.<sup>276</sup> Furthermore, many aspects of economic and social development have an exogenous character in that they are based on modern techniques borrowed from the industrialized countries and superimposed on traditional institutions.<sup>277</sup> As a consequence of such differences, it cannot be taken for granted either that the economic and social factors will have precisely the same effect in modifying motivational patterns in today's situation, or that the same degree of motivational change will be required.

135. Some writers have noted a tendency for rapid economic development in developing countries to be associated in the short run with increasing fertility. In Latin America, for instance, it has been suggested that the *direct* effect of economic development on fertility is positive, because married couples become more optimistic about their future economic status, but that in the long run the forces depressing fertility tend to be stronger than the forces making for an increase in fertility unless the increase in *per capita* income continues at a high rate.<sup>278</sup> In a rather different context there also appears to be a positive association between economic development and fertility in the Sudan, in so far as the settled and relatively prosperous population of the Gezira Scheme area has a higher fertility than the predominantly nomadic and less prosperous populations of other provinces of the same country. It seems possible however that the low fertility of the Sudanese nomads may be due in part to relatively low marriage rates, high marital instability, high frequency of venereal disease and numerous miscarriages.<sup>279</sup>

#### F. Recent and current fertility differentials within countries

136. Extensive reference has been made in the preceding two sections to differential fertility as a method for investigating those social and economic factors which account for past fertility declines in countries of low fertility as well as those which explain current levels of fertility in high-fertility areas. Although some of the

factors examined above are identical with the differential characteristics of the present section, the previous discussion explored the causal mechanism of each factor, whereas the present section is concerned more with the statistical evidence for the association between each factor and levels, or changes of level, of fertility.

137. The study of differential fertility has found widespread use as a means of forecasting fertility trends in high-fertility countries, where emerging differences in fertility levels among population groups displaying certain economic and social characteristics (namely, those which have already been established as being related to lowered fertility levels in industrialized countries) may signal an imminent fertility decline. The study of fertility differences is also useful in assessing the factors and prospects of change in the composition of a population in respect to its ethnic, religious and linguistic sub-groups. Eugenists and some analysts of social problems, especially in Anglo-Saxon countries, have been concerned with the implications for population quality of the widening fertility differential according to socio-economic status during the course of decreasing fertility, and have followed trends for signs of a contraction and even a reversal of the customary inverse association between fertility and socio-economic status. According to this point of view, the inverse association signifies that those most qualified (either in genetic terms or in terms of financial and other resources) to raise children were having the fewest and those least qualified were having the most.<sup>280</sup>

138. Generalizations based on international comparisons—so often fraught with difficulties because of incomparabilities in the data—are more than usually subject to qualifications and reservations in the case of differential fertility because of the diversity of interests of scholars working in this area. Conclusions frequently have to be drawn on the basis of not completely comparable differentials, for example, differentials referring to women of completed fertility compared with those for women of still incomplete fertility, or differentials referring to all women in a given age group compared with differentials for married women only or for women of a specified marriage cohort. Although these various forms of expressing the differentials are all legitimate research tools adapted to the special interests of the individual investigator, it cannot be taken for granted that they can be used interchangeably without affecting the validity of the generalizations being made.

## 1. URBAN-RURAL DIFFERENCES

139. The difference between urban and rural fertility in Western European countries became progressively larger during the period of fertility decline, but narrowed during the period of recovery following the Second World War.<sup>281</sup> Opposing trends were observed in some

Eastern European countries and the USSR. In Poland and the USSR, for example, the differential appears to have widened during the 1950s, but in Hungary the long-standing differential between urban and rural areas appears to have been reduced in that decade.<sup>282</sup> In the United States the gap between urban and rural fertility, which showed little change between 1920 and 1940, decreased decidedly thereafter.<sup>283</sup> In Japan in 1960, rural fertility exceeded urban fertility by 20 per cent among ever-married women 35 years old and over. It has been suggested, however, that the differential may eventually disappear with the growing sophistication of both the rural and the urban populations in successful contraceptive practice.<sup>284</sup>

140. Not only is an urban-rural differential common in low-fertility countries, but there also tends to be an inverse relationship between fertility and size of community. Thus, in the United States in 1957, the number of children ever born per 1,000 ever-married women aged 15-44 (distribution standardized for age) ranged from 1,820 for urban areas containing over 3,000,000 inhabitants, to 2,128 for urban areas of under 250,000 inhabitants, and with higher figures for the smaller urban areas and for rural areas.<sup>285</sup> Similar differentials have also been found in other low-fertility countries. In Japan and the USSR, for example, it was found that the larger the size of the community, the lower the fertility.<sup>286</sup>

141. Census and other data permit a comparison of rural and urban fertility in only a few countries of high fertility. In Latin America, child-woman ratios<sup>287</sup> and figures of average numbers of children born per woman of completed fertility show that rural fertility is universally higher than urban fertility in the region. In India and Jordan, however, there is very little difference between urban and rural fertility, but in Ceylon, the Philippines, Thailand and China (Taiwan) there is a substantial differential, rural fertility being in all cases the higher.<sup>288</sup>

<sup>282</sup> *Ibid.*, p. 126; Kiser, "Social, economic and religious factors . . ." (1967), pp. 219-220; Good, "Some aspects of fertility change in Hungary" (1964), pp. 162-163. In Bulgaria, a pronounced urban-rural fertility differential was found as early as 1899-1902, when the crude birth rate in cities was 32 as compared with 42 in the villages, and 41 in the country as a whole. Danailov, *Izsledvaniya vurkhu demografiyata na Bulgaria* (1931), p. 274.

<sup>283</sup> Kiser, "Differential fertility in the United States" (1960), pp. 78-87.

<sup>284</sup> Kimura, "Current fertility patterns in Japan" (1967), p. 217.

<sup>285</sup> Kiser, "Fertility rates by residence and migration" (1959), p. 274; also Ruggles and Ruggles, "Differential fertility . . ." (1960), pp. 183-185.

<sup>286</sup> Japan, Bureau of Statistics, *Nihon no jinko, 1960 . . .* (1963), table 23; Kono, *Shusse ryoku ni oyobosu shakai . . .* (1967), table 2; Volkov, "Zadachi i metody . . ." (1967), p. 254.

<sup>287</sup> Here defined as the number of children aged 5-9 years per 1,000 women aged 20-49. The child-woman ratio is an imperfect tool for the study of fertility differentials, as it is affected by differential infant and child mortality as well as by differential completeness of enumeration of the child population. More particularly, when used to study differences between urban and rural fertility, the ratio may also distort the rural-urban fertility differential because of age-selective migration from rural to urban areas. Carleton found, however, in his analysis of data for Latin American countries, that the bias of the urban child-woman ratio due to age-selective migration proved to be small. [Carleton, "Fertility trends . . ." (1965), pp. 18-20.]

<sup>288</sup> United Nations, *Population Bulletin . . .* (1965), pp. 131-133.

<sup>280</sup> For a description of this "evaluative" approach to differential fertility, see Westoff, "The changing focus of differential fertility research . . ." (1953), pp. 25-26; also Moore, "Sociology and demography" (1959), p. 849. The eugenicist view is frequently expressed in the issues of *Eugenics Review* (London) or *Eugenics Quarterly* (New York).

<sup>281</sup> United Nations, *Population Bulletin . . .* (1965), p. 124.

Although data on rural-urban fertility levels are available for a number of African countries, the quality of the data is such that even the direction of the differential cannot in all cases be accepted with certainty. Sample survey data which permit a comparison of the fertility level in the capital cities with that in the rural areas show no consistent pattern in the differential. Urban fertility, which was lower in Mali, Guinea and Togo, was higher in Upper Volta, the People's Republic of the Congo and Gabon, while in Chad, Senegal and Madagascar, urban and rural fertility levels were about the same.<sup>289</sup> In the United Arab Republic, recent census and vital statistics data point to higher urban than rural fertility.<sup>290</sup>

142. The contrast between the consistently lower urban than rural fertility in Latin America and the absence of any differential pattern in either Asia or Africa has been noted by Carleton who relates it to some of the different aspects urbanization assumes in these regions. Internal migration is predominantly female in Latin America and the urban centres generally have a highly unbalanced sex ratio (with the consequence that urban women marry later on the average and a larger proportion never marry at all); in Africa and Asia, on the other hand, the pattern is usually just the reverse, with males predominating in the cities. Furthermore, in many of the cities of Africa and Asia, women's roles are structured in such a way that they are less exposed to many of the influences thought to be important in lowering fertility. For example, tradition often does not sanction the employment of women outside the home and certain kinds of work that are customarily undertaken by women in Latin America (e.g. domestic service) are performed by men.<sup>291</sup>

## 2. EDUCATIONAL STATUS

143. In low-fertility countries there is generally an inverse relationship between fertility and education of the parents, but the magnitude of the differential has diminished in recent decades, and a direct relationship has even been observed at the highest educational levels in a few countries.<sup>292</sup> In the United States, according to Kiser, "The differentials in fertility rates by education . . . were still strong in 1960 although they lessened somewhat over the previous decade. Although the relative increase in fertility of the ever-married college graduates tended to be larger than that of women of lower educational attainment, the college graduates still had the lowest fertility rates at all ages. The ever-married white women whose education was limited to elementary school were

of conspicuously high fertility".<sup>293</sup> Another writer, also basing his analysis on 1960 census data, has found support for the hypothesis that in the United States, education of the wife has a stronger inverse relationship to fertility than education of the husband.<sup>294</sup> In view of the close relationship between educational status and other socio-economic characteristics of population groups, the relationship between education and fertility was studied in isolation from the other characteristics in an analysis of 1940 census data for the United States. It was found that an inverse relationship between education and family size was not always present at the highest education levels.<sup>295</sup>

144. In Europe the relationship between fertility and education is not systematic. In Sweden, the Netherlands, and the United Kingdom (England and Wales), the fertility of the better-educated is above the average levels in their respective populations. This positive relationship at the highest educational levels, however, is of comparatively recent origin. In the Netherlands, for instance, according to data from the 1947 census, the ratio of university graduates' fertility to national fertility increased from 77 for marriages contracted in 1914-1918 to 102 for those originating in 1939-1943.<sup>296</sup> Again, in the Federal Republic of Germany, for married women aged 45 and over, the mean number of children ever born per married woman was inversely associated with educational status all the way through the educational scale, according to a survey undertaken in 1958, but, for younger married women, the relationship between educational background and both past fertility and expected fertility was "U"-shaped, the highest fertility levels relating to those with the most education and the least education.<sup>297</sup> Breznik found a strong inverse relation between level of education and fertility in Yugoslavia.<sup>298</sup> Another study in that country showed that of three socio-economic indicators examined (*per capita* income, degree of urbanization and level of education), fertility was most closely associated with level of education.<sup>299</sup>

145. At least three intermediate variables are involved in the relationship between educational attainment and fertility: age at marriage, frequency of marriage, and use of contraception. Examining American nuptiality,

<sup>289</sup> Kiser, "Social, economic and religious factors . . ." (1967), p. 222.

<sup>294</sup> Dinkel, "Education and fertility in the United States" (1965).

<sup>295</sup> Ruggles and Ruggles, "Differential fertility . . ." (1960), pp. 169 ff. In comparing the family size of women who had completed four years of high school with the family size of college women, a positive relation between education and family size was found among women whose husbands earned \$5,000 or more. When the husband's occupation was held constant, a similar direct relation between education and family size appeared in the comparison of four-year high school women with college women for all occupational groups except for women married to professional men. The traditional inverse relationship between education and family size was observed at lower educational levels.

<sup>290</sup> Zikry, "Fertility differentials . . ." (1965). See also El-Badry, "Trends in the components of population growth . . ." (1965), p. 144.

<sup>291</sup> Carleton, *Crecimiento de la población . . .* (1966), p. 33; United Nations, *Report on the World Social Situation, 1957* (1957), pp. 118-120.

<sup>292</sup> United Nations, *Population Bulletin . . .* (1965), pp. 122-123, 127-128.

Tietze and Lauriat found that for 1940 and 1950 the highest ages at marriage occurred in the extremes of the range of education, that is, among persons with no schooling and among those with four or more years of university education.<sup>300</sup> Also in 1940 the proportion of women married between ages 20 and 49 generally decreased with educational attainment. But this pattern was much less noticeable in the data for 1950.<sup>301</sup> The relationship between education and receptivity to the use of contraception is illustrated by the case of Protestants in the United States. "Eighty-five per cent of college-educated Protestant wives approved [of family limitation] wholeheartedly, and none disapproved under all circumstances. On the other hand, only 50 per cent of the Protestant women with a grade school education approved completely, and 4 per cent were strongly opposed".<sup>302</sup>

146. In Japan, too, a partial explanation of fertility differentials, both with regard to urban-rural residence and educational attainment, appears to relate to the degree of practice of birth control. According to surveys conducted in that country, 54 per cent of couples practised contraception when the husband had more than 13 years of schooling, but only 38 per cent when the husband had been at school for nine years or less.<sup>303</sup>

147. Data for the study of differential fertility according to educational attainment of the husband or wife are available in only a small number of high-fertility countries. For the United Arab Republic, 1960 census data show an inverse relationship between educational attainment of women and their fertility, the lower fertility of the well-educated married women being due in part to a later age at marriage and in part, almost certainly, to a greater utilization of contraception.<sup>304</sup> In Bangalore City, India, women with high school or university education were found to have fewer children, on the average, than women of lesser educational attainment. The differential was much reduced, however, when the data were standardized by duration of marriage and age at marriage. The lower fertility of the more highly educated women thus appears to result partly from their later age at marriage, and partly from attempts to limit family size, with the former factor seemingly the more important.<sup>305</sup> In Taichung in China (Taiwan), however, the inverse relationship applied throughout the educational scale for married women aged 35-39 years. According to a survey conducted in 1962, wives with no education had an average of 5.7 live births and those of the highest educational status had only 3.6. Education was positively associated with use of family limitation methods.<sup>306</sup> Similar findings emerged from a

survey undertaken in Greater Santiago in Chile in 1959, where women in the 35-50 age group who had received no schooling at all, or only one year of primary education, had an average of 4.41 live births, while women with at least four years of higher education had an average of 2.36 live births.<sup>307</sup>

### 3. ECONOMIC STATUS GROUPS

148. Many studies have found an inverse relation between economic status, as measured by income or some other criterion, and fertility, but there is evidence that this traditional differential has been undergoing substantial change. In a study based on 1935 data for the United States, Kiser found that, except for the lowest income groups, there was no well-established inverse relation between level of income and fertility among urban native white women, though the inverse relationship did apply to foreign-born white women and was strongest among non-white women.<sup>308</sup> A 1952 survey found an inverse relationship between fertility and husband's income for non-farm women aged 45 years and over, but not for younger women.<sup>309</sup> In a study among women of completed fertility in Detroit, Goldberg found no significant relationship between income and fertility among the indigenous urban women, though an inverse relationship existed among the rural migrants.<sup>310</sup> Freedman and Slesinger's analysis of data for white non-farm women in the reproductive ages showed no negative relationship between income and fertility among the indigenous non-farm couples, while for farm migrants there was a substantial inverse association.<sup>311</sup>

149. Rental value of the dwelling unit has also been used as a measure of economic status for studying fertility differentials in the United States. The Indianapolis Study revealed a strong inverse relationship between this measure and fertility, except that at the upper rental values, a direct relationship appeared; that is, after a rent in excess of \$60 per month, an advance in rent was associated with a rise in fertility.<sup>312</sup> Such an obverse "J" curve has been observed for the United States as a whole.<sup>313</sup>

150. In Europe, several studies in the 1930s also revealed the inverse relationship between income and fertility. For example, in a family budget survey carried out in the Soviet Union in 1934, Strumilin found a clear inverse association between monthly income and the number of births.<sup>314</sup> Several studies reported a narrowing of the differences between the fertility of the population in different economic quarters of big cities.<sup>315</sup> Other inquiries, however, showed no diminution of differentials.<sup>316</sup> In certain of these studies it was found that fertility did not show a continuous decline with rising economic status. Thus, though the birth rate in very poor districts was usually higher than in other districts, there was no decrease in fertility after a given level of prosperity was reached. Some studies showed that the wealthiest districts had more children than those districts next below them in the economic scale. From a study conducted in twenty villages in southern Poland in 1948 linking the size of peasant holdings with the number of children in the family, Stys concluded that rich peasants had much larger families than poorer ones.<sup>317</sup> Among those who had matriculated in Sweden, fertility was generally found to vary positively with level of income, though fertility rates were lower in the very highest income class than the class immediately belows.<sup>318</sup> Data for the non-agricultural population in the Federal Republic of Germany, based on a 1962 sample survey, revealed a positive correlation between income of husband and family size. This correlation, which was most evident in the cities, diminished in strength with decreasing size of community. In view of this observed relation between income and size of family, Schwarz has suggested that increased income may lead to larger families in the future, since modern man is able, through contraception, to adapt his family size ideal to his material situation.<sup>319</sup>

<sup>314</sup> Strumilin, *Problemy ekonomiki truda* (1957), chap. 5. This study, which distinguished between recent migrants from rural areas and long-term urban residents, found that income appeared to be the decisive factor, since low-income long-term urban residents had higher fertility than high-income newcomers from villages.

<sup>317</sup> Stys, "The influence of economic conditions ..." (1957), p. 136. Other authors, however, have found size of holding to be an unsatisfactory indicator of economic level. For example, a study which examined the relation between size of holding, income and family size of Polish peasants found only a small positive correlation between the first two variables, but a clear inverse correlation between the latter two. See Chojnacka, *Konsumpcja żywności w rodzinach rolniczych* ... (1963), pp. 20-27.

<sup>318</sup> Moberg, "Marital status and family size ..." (1950), pp. 124-125.

<sup>319</sup> Schwarz, "Nombre d'enfants suivant le milieu ..." (1965), pp. 87-88, 91. See also Witt, "Differential fertility" (1966), p. 4. In commenting on the 1962 survey data, Witt argues that the relevant factor that ought to be used is not the absolute amount of income, but "the deviation of personal income from profession specific norms ...".

151. Occupation, especially of the husband, has been probably the most widely utilized index of socio-economic status in the study of fertility differentials. Changes in occupational distribution of the population of industrially advanced countries have accompanied the general declines in fertility. Relatively high fertility has been associated with the primary industries, particularly agriculture and mining, while lower rates of fertility have been associated with the professional classes, white-collar workers, and urban industrial workers.

152. During periods of declining fertility, the extent to which different occupational groups participate in the decline often varies within a country, and from one country to another.<sup>320</sup> Data from the 1911 census of England and Wales and the 1946 family census permit a systematic analysis of the relationship between occupation and fertility for cohorts married in the last decades of the nineteenth century up to the 1920-1924 marriage cohort. These data clearly show the inverse relationship between fertility and social status categories based on occupation, although there are some important exceptions to the pattern in the 1946 family census data. As fertility declined steadily among wives of both non-manual and manual workers, the gap between these two broad groups increased in the latter part of the nineteenth century, but became stabilized some time around the turn of the century, with the excess fertility of the manual group remaining relatively constant at about 40 per cent.<sup>321</sup> In Japan, the decline in fertility which has taken place since 1920, and particularly since the end of the Second World War, has affected all occupational categories. While data on completed fertility suggest that there may have been some widening of the gap between occupational groups in the early period of the decline, the differential has since narrowed, and recent fertility surveys indicate a trend towards convergence.<sup>322</sup>

153. In the United States, available evidence suggests that there was a widening of the fertility differential by occupation in the early years of this century, followed by a narrowing, as a result of greater decline among the lower socio-economic classes. After the Second World War, the gap narrowed further owing to the relatively greater increases in fertility among the upper socio-economic classes.<sup>323</sup> In Hungary, the historically higher fertility of the agricultural, as compared to the non-agricultural, population has actually been reversed. The fertility of farm women was 30 to 40 per cent higher than that of non-farm women before the First World War, and

<sup>320</sup> For a discussion of changes in fertility according to occupational status in selected European countries, see Johnson, "Differential fertility in European countries" (1960), pp. 55-60.

<sup>323</sup> Kiser, "Social, economic and religious factors ..." (1967), p. 221; Grabill, Kiser and Whelpton, *The Fertility of American Women* (1958), pp. 181-182.

as much as one-half to two-thirds higher in the interwar period. By the late 1940s this difference had disappeared, and by 1962-1963 the fertility of non-farm women was more than 25 per cent higher than that of farm women. The latter trend, however, was believed to be temporary.<sup>324</sup>

154. Direct information on the relationship between fertility and either economic or occupational status is very limited for high-fertility countries, and can usually be found only in special demographic surveys covering portions of a country which may not be typical of the whole. Census data for the United Arab Republic on family size by duration of marriage and husband's occupation indicate an inverse relationship between socio-economic status and family size in urban areas and a positive relationship in rural areas. It has been suggested that deferment of marriage among agricultural labourers in rural areas may be a factor contributing to the latter pattern;<sup>325</sup> however, the data were not standardized by age at marriage to test this hypothesis. For India, National Sample Survey data show no clear differentials in fertility among the four broad caste groups of Hindus at selected years after marriage.<sup>326</sup> However, in studies of Uttar Pradesh, Sinha found a distinct negative association between income and fertility, and Rele also found that among women married for more than fifteen years there was a negative relationship between social class and level of fertility, but considered that this differential might be associated with differential rates of widow remarriage.<sup>327</sup> From the Mysore Study it appears that, in rural areas, the higher the economic status (measured in terms of type of house) the larger the size of the family, but this is not conclusive since no such relationship characterizes the fertility pattern of Bangalore City.<sup>328</sup> Analysis of a demographic survey taken in Morocco in 1962 showed that the wives of professional men had the smallest completed family size with an average of 5.0 children, and the wives of merchants and retailers the largest with an average of 6.2 children, the corresponding figures for the population in agricultural and artisanal occupations being 5.5 and 5.4, respectively. Here the spread is not great and there does not appear to be a definitive inverse relationship between economic status and fertility.<sup>329</sup>

## 5. EMPLOYMENT OF WOMEN

155. Numerous studies have shown an inverse relationship between family size and the extent of female participation in the labour force; i.e., married women who are gainfully employed generally have fewer children than

other married women.<sup>330</sup> This relationship has been found to be more marked in the industrialized than in the non-industrialized countries, and in urban more than in rural areas. Moreover, it is the women who work for wages, rather than the self-employed or unpaid family workers, who have significantly lower fertility than non-working women.<sup>331</sup>

156. The interpretation of these observed differentials remains in some doubt, however, since a causal relationship has yet to be established. Some authors have emphasized the possibility that women who work may on that account abstain from childbearing to a greater extent than non-working women<sup>332</sup> in order to realize their goals of achieving or maintaining a higher standard of living. Those who believe that female employment outside the home is an important factor tending to lower fertility have advocated increasing opportunities for such employment in high-fertility areas as a means of reducing birth rates.<sup>333</sup> Other writers have been less optimistic about the possibility that increased entry of women into the labour force would bring a reduction in high birth rates. They have rather stressed the selection aspect, whereby women with no children or very few children find it easier to accept employment away from the home.<sup>334</sup>

157. Efforts to assess the possible effects of female labour force participation on fertility are complicated by the intervention of other variables such as socio-

<sup>330</sup> In addition to the works cited in chapter IX, section A, see, for example, Vostrikova, "Female fertility and methods of studying ..." (1967), p. 243; Henripin, *Tendances et facteurs ...* (1968), p. 307; Collver, "Women's work participation and fertility ..." (1968); Jaffe, *People, Jobs and Economic Development ...* (1959), pp. 186-194.

<sup>331</sup> Jaffe and Azumi, "The birth rate and cottage industries ..." (1960), pp. 59-61. Federici, examining data for Italy, found the usual negative correlation between female employment and fertility, except for women at the higher ages, who worked predominantly in agriculture, and often as unpaid family workers. Federici, "A női munka hatása a termékenységre" (1967).

<sup>332</sup> The results of a survey in Czechoslovakia which indicated that the prolongation of maternity leave was a factor influencing positively the birth of the third child would seem to suggest that a certain proportion of employed women had restricted or postponed childbearing prior to the liberalization of maternity benefits. Kučera, "Vyzkum třetích a čtvrtých dětí narozených ..." (1965).

<sup>333</sup> Thus, Jaffe and Azumi, in their study of the relationship between different types of female employment and fertility levels in Japan found that women who worked away from the home averaged about one-half child fewer than women working in cottage industries or remaining outside the labour force. The authors concluded that, from the point of view of reducing the birth rate, the most desirable industries to introduce would be those using large quantities of female labour away from the home. Jaffe and Azumi, "The birth rate and cottage industries ..." (1960), p. 62.

<sup>334</sup> In a study of female employment in Lima, Peru, Stycos found that the largest fertility differential between working and non-working women occurred in the lowest socio-economic class, the class least likely to practise contraception. He concluded that it seems likely that "... employment status is more often a consequence of marital fertility than a cause". Stycos, "Female employment and fertility in Lima, Peru" (1965), pp. 49, 53-54. Another writer has theorized that in societies where the roles of mother and worker are relatively incompatible, the origin of the negative association between female employment and fertility is related to the presence or absence of birth control technology. Where know-

economic status, education and the like, all of which are interrelated.<sup>335</sup> Thus the likelihood of a woman's entering the labour force may be influenced by her education, which in turn depends on other socio-economic factors. Recognizing the possible importance of other factors, some analysts have examined the relationships between activity status and fertility separately for different educational and income groups. The findings show that the fertility differentials between active and inactive women persist even when other factors are controlled. Such detailed analyses are not numerous, however, and do not permit conclusions concerning the relative force of the various factors.<sup>336</sup>

## 6. RELIGIOUS AND ETHNIC DIFFERENCES

158. In many societies fertility differences have been observed among population groups differentiated on the basis of common national heritage, language or religion, and sharing common attitudes and cultural patterns. The question immediately arises whether the observed differences result mainly from the group's social and economic characteristics (educational attainment, occupational structure, urban-rural residence, income level and the like), which differ from those of the rest of the population, or whether they reflect cultural factors peculiar to the group. Even where economic and social conditions have been equalized among different population groups, cultural patterns formed under previous conditions may tend to persist, and it has frequently proved difficult to determine the relative weight of these various influences in accounting for intergroup fertility differences.

159. So far as religion is concerned, a number of studies in various European countries, and in the United States and Canada, have found fertility to be higher among Catholics than among Protestants and Jews, but while the differential appears to be narrowing in most of these countries, in the United States recent evidence has indicated a widening of the gap. The trend towards a diminution of the differential in a number of countries has been attributed to several factors: (a) a modification of traditional attitudes on the part of certain religious bodies towards ideals and practices which affect family size; (b) a weakening of the influence of religious doctrine

and tradition; (c) a lessening in the non-religious differences which appear in part to have contributed to the religious differential in fertility. Regarding the second of these factors, several studies on the relation between religion and fertility have not been content merely to study religious affiliation; rather, they have concerned themselves with the effects of "religiousness", as measured by the intensity of religious beliefs and practices. As to the third factor, in any study of fertility differentials based on religion, it is important to consider to what extent the observed fertility differences between religious groups may be due to differences in income, occupation, education, urban-rural residence or some other non-religious factors. These studies have found, generally, that while socio-economic and residential factors often account for a substantial part of the religious fertility differential, they do not account for all of it.

160. In the United States, where information on religion is not collected in the census, the demographic characteristics of religious groups have been investigated by means of sample surveys.<sup>337</sup> These have generally found that among the three major religious groups, Catholics have the highest fertility. While fertility differences based on the traditional measures of socio-economic status have been decreasing, religious differences have emerged in recent years as perhaps the strongest of the socio-economic determinants of fertility.

161. Data from the Growth of American Families (GAF) studies of 1955 and 1960, and from some 1962 studies conducted by the Population Studies Center of the University of Michigan, suggest a growing differential in fertility between Catholics and non-Catholics. In the 1955 study, the average number of children borne by Catholics was only slightly higher than for Protestants when the duration of marriage was controlled. By 1962, however, as a result of an increase in Catholic fertility, Catholics had borne 0.6 more children than non-Catholics, despite the shorter average duration of their marriages at time of survey.<sup>338</sup> Regarding the Protestant-Jewish differential, a special analysis of the 1955 GAF data attributed the lower fertility of the Jews in large measure

(Footnote 334 continued)

ledge of birth control methods is present, women who work may voluntarily restrict the size of their families, while at the same time there is a self-selection of sterile and subfecund women into the labour force, because their lighter household duties permit them to work. In the absence of birth control technology, however, only the self-selection factor is of importance. Weller, "The employment of wives ..." (1968), p. 513.

<sup>335</sup> For example, Morsa found in his study of working-class women in a suburb of Brussels that the same motive—that of economic necessity—was often responsible for women working and for their abstention from child-bearing. Morsa, "Travail des femmes et natalité" (1959), p. 260.

<sup>336</sup> Jaffe, analysing data for Puerto Rico, found a widening of fertility differences between working and non-working women at higher educational levels, whereas Henripin found the opposite trend for Canada. The latter author's data, however, showed that the fertility differential for working and non-working women widened with increasing income. Jaffe, *People, Jobs and Economic Development* ... (1959), p. 187; Henripin, *Tendances et facteurs* ... (1968), pp. 306-314.

<sup>337</sup> Some of the major studies have been the Indianapolis Study [Whelpton and Kiser, eds., *Social and Psychological* ... 5 vols., (1946-1958)]; the Growth of American Families Studies [Freedman, Whelpton and Campbell, *Family Planning, Sterility and Population Growth* (1959), and Whelpton, Campbell and Patterson, *Fertility and Family Planning* ... (1966)]; and the Princeton Study [Westoff et al., *Family Growth in Metropolitan America* (1961), and Westoff, Potter and Sagi, *The Third Child* ... (1963)]. While the Indianapolis Study was restricted to Protestant couples only, a preliminary household survey yielded data permitting a comparison of fertility for the three major religious groups.

<sup>338</sup> Freedman, Whelpton and Campbell, *Family Planning, Sterility and Population Growth* (1959), pp. 275-279; Whelpton, Campbell and Patterson, *Fertility and Family Planning* ... (1966), pp. 75-77, 123-124; Freedman, Goldberg and Slesinger, "Current fertility expectations ..." (1963), pp. 376-379. Whereas the analyses of data from these three studies pertain to the white population only, a 1957 survey by the United States Bureau of the Census, which included the non-white population, showed virtually no fertility differential between Protestant and Catholic women 15 to 44 years old. United States, Bureau of the Census, *Statistical Abstract of the United States 1958* (1958), p. 41. Differences reflecting religion, however, might be obscured by the higher proportions of Negroes and rural residents in the Protestant group.

to their greater concentration in urban areas and their higher socio-economic status.<sup>339</sup> On the other hand, Goldscheider, in his review of the existing literature on Jewish fertility, concludes that the consistently lower fertility of the Jews cannot be adequately explained in terms of their distinct social and economic characteristics, but that the influences arising from their minority-group status must be taken into account.<sup>340</sup> Studies which have investigated the effects of "religiousness" (as defined in terms of frequency of church attendance, the amount of education received in church-related schools, the importance of religion in daily life etc.) on fertility, have generally found a strong association between these measures and fertility among Catholics, but little relationship among Protestants or Jews.<sup>341</sup>

162. Several studies in the United States have shown a direct relationship between the number of children expected or desired by Catholic women and the amount of their education received in church-related schools. Below the college level, the religious educational experience appears to have had a significant influence on fertility expectations,<sup>342</sup> but the higher number of children desired by women attending Catholic colleges reflects the tendency of women already oriented towards large families to select such institutions, as family-size desires of first- and fourth-year women were found to be quite similar.<sup>343</sup>

163. An analysis of 1961 census data for Canada seems to indicate a narrowing of the fertility differential between Catholic and Protestant women who were over forty-five years old at the census date. An apparent convergence is also found among the younger age groups, but because of the differences in marital patterns between Catholics and Protestants (the Catholics tend to marry later than the Protestants and therefore bear their children at a later age), it is not possible to draw firm conclusions regarding trends in the differential for women who were still in their childbearing years. An important factor in the narrowing of the fertility differential has been the rapidly falling fertility of the French Catholics of Quebec. However, the complex cross-currents of ethnic group membership, urban-rural residence and geography make it difficult to sort out the influence of the religious factor which, the authors feel, furnishes a relatively weak explanation for the observed differentials.<sup>344</sup>

<sup>343</sup> Westoff and Potvin, *College Women and Fertility Values* (1967), chap. 5.

<sup>344</sup> Krotki and Lapierre, "La fécondité au Canada selon la religion ..." (1968). The findings of this study confirm, for the most part, the conclusions of an earlier study by Burch. See Burch, "The fertility of North American Catholics ..." (1966). Henripin found a marked persistence of the Catholic-Protestant differential when comparing fertility of English-speaking groups only. See

164. In the Federal Republic of Germany, a comparison of fertility data for Catholic and Protestant marriage cohorts, based on the 1950 census, showed a progressive contraction of the differential for successive marriage cohorts. For the most recent cohort studied, that of 1937-1940, the differential had entirely disappeared in localities of 100,000 or more inhabitants, although in smaller localities Catholics had somewhat higher fertility. Comparable data are not available for later dates, but a 1962 sample survey which permits the comparison of fertility for a predominantly Protestant region (Lower Saxony) with a predominantly Catholic one (Bavaria) confirmed that excess Catholic fertility is found almost exclusively in the less populous localities.<sup>345</sup>

165. In the Netherlands, the marked differential in fertility between Catholics and Protestants which already existed among late nineteenth-century marriage cohorts, was maintained well into the twentieth century; by the early 1960s, however, there was evidence that a narrowing of the differential was under way.<sup>346</sup> While geographic and economic differences between the religious groups have been offered as explanation for the persistence of the differential, the importance of the religious factor has been particularly stressed by some writers.<sup>347</sup>

166. Fertility differences between Catholics and Protestants in Switzerland widened in the early decades of this century as fertility declined much more rapidly among Protestants than among Catholics. Although some narrowing of the differential appears to have occurred since 1930, post-war trends have been difficult to assess because of the heavy and predominantly Catholic immigration in the 1950s and 1960s.<sup>348</sup>

<sup>347</sup> Van Heek found the fertility differential to be as high as 40 to 80 per cent in Catholic and Protestant districts with similar socio-economic structure. Not only was the fertility of Dutch Catholics higher than that of other Dutch religious groups; it was also found to be considerably higher than that of Catholics in border areas of Belgium and Germany. According to Van Heek, the Catholic-Protestant differential resulted from the strong indirect social control exercised by the Dutch Catholic Church, with its pro-natalist orientation, and the position of Dutch Catholics as a strong minority in competition with a dominant majority. Van Heek, "Roman-Catholicism and fertility in the Netherlands ..." (1956).

<sup>348</sup> See Mayer, "Recent demographic developments in Switzerland" (1957), p. 349; and his "The impact of postwar immigration ..." (1966), pp. 83-85; also Switzerland, Bureau fédéral de statistique, *Annuaire statistique de la Suisse, 1966* (1966), pp. 33, 71. As the Swiss Protestants are mainly town-dwellers while the Catholics inhabit the rural areas, several writers have examined fertility within a particular occupational group or among regions with similar economic characteristics, in an attempt to isolate the in-

(Continued on next page)

167. In Yugoslavia marked differences in birth rates have been established among the different ethnic nationalities. In 1961, crude birth rates ranged from about 46 for the Albanians to around 20 for the Serbs, Croats, Slovenes and some other groups. The fact that differences in fertility between various ethnic groups in the same region are sometimes smaller than differences between the same ethnic groups in different regions is evidence of the strong influence of social and economic factors on fertility levels.<sup>349</sup>

168. Although data on fertility levels by ethnic nationality are limited for the USSR, the birth rate for each Union Republic may be considered to reflect, to a large degree, the rate for the major nationality of that Republic. These rates vary widely from one Republic to another. In 1962, the Azerbaijan and Turkmen Republics had birth rates over 40 per 1,000 population, a figure that was 2.5 times greater than that of the Estonian and Latvian Republics, with a rate of 16. Uralanis has attributed such variations to distinctive traditions and customs which have evolved in the course of many generations.<sup>350</sup>

169. Wide differences in fertility levels in Canada between the French-speaking and English-speaking population have been well-documented, but recent evidence suggests the gradual disappearance of this differential over time. A 1961 census monograph, which attempted to isolate the strictly linguistic-cultural factor by eliminating the influence of religion, urban-rural residence, education and income, found that there was no systematic superiority in fertility among 35-39-year-old French-speaking Catholic women over their English-speaking counterparts in the same educational and income groups. Indeed, for certain categories the fertility of the French-speaking group was lower. Among women aged 45-49 years, however, the French-speaking women did have higher fertility in most categories, and a still wider

differential was observed among women aged 65-74 years.<sup>351</sup>

170. In Israel, fertility levels among Jewish immigrant groups of different cultural backgrounds reflect the levels prevalent in their country of origin. Thus, the fertility of "Oriental" immigrants (those from Africa and Asia) greatly exceeds that of women from Europe and America. When the comparisons are made for women of similar educational attainment, the fertility differentials are reduced but still remain substantial, underlining the importance of cultural factors in reproductive behaviour.<sup>352</sup>

171. Differences in fertility levels have also been observed among different racial groups in multiracial societies. Thus, crude birth rates of the white and non-white population in the United States differ considerably, non-white fertility being consistently higher.<sup>353</sup> These differences can be explained by socio-economic factors, as it has been shown that, for groups with similar educational achievement, the fertility of non-whites who have had no southern farm background does not differ greatly from that of whites.<sup>354</sup>

172. Fertility differences among population groups differentiated on the basis of religion, race, language or tribe have also been noted in high-fertility societies. In Brazil, where fertility is high for all population groups, the somewhat lower fertility of Negroes as compared with the white and mestizo groups is due mainly to the larger proportion of childless women among the Negro women, who appear to be at a certain disadvantage in sexual and marital selection.<sup>355</sup> In South Africa, large differences in fertility levels among the major racial groups can be explained mainly in terms of the vast differences in socio-economic level.<sup>356</sup> Analyses of census data for Bolivia, Ecuador and Peru have suggested that fertility is higher in the predominantly Spanish-speaking regions, as compared with the Indian-speaking regions, despite the fact that the latter areas have a lower level of economic

(Footnote 348 continued)

fluence of the strictly religious factor. Mayer and Brüscheiler concluded, in their separate studies, that the religious factor was less important than the economic-occupational factor as a determinant of fertility, but that in an economically homogeneous population, the religious factor still retained considerable importance. Brüscheiler, "Konfession und Geburtenrückgang" (1938), p. 49; Mayer, *The Population of Switzerland* (1952), pp. 104-111. An analysis of 1941 census data showed that fertility of farmers' wives was higher among Catholics than among Protestants. Nixon, "Some demographic characteristics ..." (1963), p. 47.

<sup>349</sup> For example, the 1961 birth rates for the Albanians and the Serbs in the region of Kosovo and Metohija were 46.3 and 31.3, respectively, while the Serbs of Vojvodina had a birth rate of only 17.6. Thus, the difference in birth rates between these two ethnic groups in the same region was smaller, relatively, than that between the Serbs in the two different regions. Breznik and Sentić, "Les études démographiques et la nationalité ..." (1966), pp. 416-417. See also Yugoslavia, Centar za Demografska Istraživanja, "Demografski razvitiak narodnosti u Srbiji" (1967), p. 122.

<sup>350</sup> Uralanis, "Dynamics of the birth rate ..." (1967); and his *Rozhdaemost i prodolzhitel'nost zhizni v SSSR* (1963), pp. 38, 50. One of the factors contributing to such variations in fertility is age at marriage. In the Baltic Republics, only 4 to 5 per cent of women aged 16-19 years were married in 1959, in the Turkmen Republic the figure was 32 per cent, while in the Kirghiz Republic it was over 44 per cent. Studies by Sifman, and Karakhanov and Aliakberova, of fertility in the Central Asian Republics, indicate the influence of a variety of factors, including ethnic ones, on fertility levels. See Sifman, "Dinamika rozhdaemosti ..." (1970); and Karakhanov and Aliakberova, "Nekotorye rezultaty ..." (1970).

<sup>351</sup> Henripin, *Tendances et facteurs ...* (1968), pp. 189-197. For an analysis of data from the 1941 census, see Charles, *The Changing Size ...* (1948), chap. 4.

<sup>352</sup> Israel, Central Bureau of Statistics, *Marriage and Fertility, part 2 ...* (1967), table 15. See also Matras, *Social Change in Israel* (1965), pp. 180 ff.

<sup>353</sup> In the period 1951-1961, for example, the birth rate of non-whites ranged between 32 and 34 per 1,000 population, while that for whites was some 10 points lower. Whelpton, Campbell and Patterson, *Fertility and Family Planning ...* (1966), p. 334. In 1964, the fertility rate (births per 1,000 women aged 15-44 years) for non-whites exceeded that for whites by 42 per cent. United States, National Center for Health Statistics, *Natality Statistics Analysis, United States—1964* (1967), p. 11.

<sup>356</sup> For discussions of differences among the Bantu, Coloured, Asian and European populations with respect to demographic, occupational and income characteristics, see Sadie, "Opening discussion ..." (1964), p. 144; Horwood, "The social framework of economic development ..." (1964), p. 176; Lombard, "The determination of racial ..." (1964).

development.<sup>357</sup> Demographic sample surveys in a number of African countries have recorded wide variations in fertility, as well as sterility, from one ethnic group to another (see section B.4 above), but it has not been possible to determine the relative influence of the various factors involved.<sup>358</sup>

173. A few surveys which have examined fertility differences among Moslem and non-Moslem groups in the same country suggest that while such differences are slight in the more backward sectors, Moslem fertility is higher than that of non-Moslems in the more developed sectors. Thus, there appeared to be no significant differences in fertility between Moslems and non-Moslems in rural areas of Lebanon and the United Arab Republic, nor among illiterates in Ghana.<sup>359</sup> On the other hand, among urban residents in Lebanon, educated Christians were found to have lower fertility than educated Moslems, and uneducated Christians had lower fertility than uneducated Moslems.<sup>360</sup> Similarly, in the United Arab Republic, Rizk found higher fertility among Moslems than among non-Moslems in the cities which did not appear to be related to differences in socio-economic status.<sup>361</sup>

### G. Prospects for future trends of fertility

174. As demographic research developed in the third and fourth decades of this century, it was fertility, among the components of population growth, that was thought to be most amenable to projection in both developed and developing countries. It was considered that in developed countries fertility would continue its downward movement, perhaps achieving stability at levels sufficient for the maintenance of the population, but more likely resulting ultimately in population decline. In countries then agricultural in economic base, fertility was assumed to be high and very resistant to change until some future period when industrialization and urbanization would initiate and sustain declines in mortality and

later declines in fertility. In industrialized countries fertility trends in the post-war period have not borne out these earlier predictions, and new research has brought to light complexities in the historic changes in fertility in these countries. Moreover, fertility levels in developing countries are now known to be more diverse than was formerly presumed, and the reasons for this diversity are as yet not well understood. Advances in methodology and analytical technique now permit the measurement of fertility levels over wider areas and with greater precision, but they do not provide a sufficient basis in fact or in theory for the evaluation of future fertility trends. The major determinants of future developments lie in the responses of people and governments in situations that are new, not merely in the developing countries of currently high fertility, but in the world as a whole.

#### 1. PROSPECTS IN AREAS WHERE FERTILITY IS NOW HIGH

175. There now exist a number of conditions in the less developed countries that are favourable to a reduction in birth rates. The increasing pressures that population growth places on families, villages, and the larger society, are stimulants both to governmental actions and to family decisions. Recognition of the hazards to national development and family welfare inherent in the continuation of high rates of population growth has led an increasing number of Governments to adopt programmes aimed at moderating fertility. The effectiveness of these programmes in transforming the attitudes, decisions, and actions of the people has major relevance for the future trend of fertility.

176. While there is agreement that fertility levels in the developing countries will decline with modernization, the time of onset and the tempo of the decline remain problematic. Research is needed in order to determine what factors in the development process constitute critical turning points that are accompanied by substantial shifts in attitudes and behaviour. There is evidence, for example, that at the lower levels of educational attainment, groups of individuals differing with respect to years of schooling completed show virtually no significant differences in average fertility, though at the higher levels, marked fertility differences are associated with differing levels of educational attainment.<sup>362</sup> It is essential to learn more about the kind and amount of education and about the nature of other forces of modernization that are required in order for new behaviour patterns to begin to assert themselves.

177. The inability to forecast future changes accurately, or perhaps the inherent unpredictability of such changes, has often led demographers to prepare several alternative series of fertility projections for a particular population. The common procedure is a series of three projections to delimit the range within which future changes would be most likely to lie, with the central projection being regarded as most likely. Based on observations of the course of past fertility in low-fertility countries, the United

<sup>357</sup> Stycos, "Culture and differential fertility in Peru" (1963); Heer, "Fertility differences between Indian ..." (1964). The two authors assessed somewhat differently the probable reasons for these differentials; Stycos attached importance to differential mating patterns, while Heer suggested that the differences might possibly be due to the existence of indigenous birth control practices in the Indian-speaking regions.

<sup>358</sup> See, for example, Congo (Brazzaville), Service de statistique, and France, Service de Coopération, *Enquête démographique 1960-1961* ... (1965), pp. 46-47; Central African Republic, Service de la statistique générale, and France, Service de Coopération, *Enquête démographique en République centrafricaine, 1959-1960* ... (1964), pp. 98, 104; Chad, Service de statistique, and France, Service de Coopération, *Enquête démographique au Tchad 1964* ... (1966), vol. 1, pp. 127-128; Gabon, Service de statistique, and France, Service de Coopération, *Recensement et enquête démographiques, 1960-1961* ... (1965), pp. 88-90.

<sup>359</sup> Yaukey, *Fertility Differences in a Modernizing Country* ... (1961), p. 31; Rizk, "Population growth and its effect ..." (1964), p. 172; Busia, "Some aspects of the relation ..." (1954), p. 346.

<sup>360</sup> Yaukey, *Fertility Differences in a Modernizing Country* ... (1961), p. 79.

<sup>361</sup> Discussed in *ibid.*, p. 42, based on Rizk's doctoral dissertation, *Fertility Patterns in Selected Areas in Egypt*, Princeton University, 1959.

<sup>362</sup> See, for example, United Nations, *Report of the Ad Hoc Committee of Experts* ... (1969), p. 26.

Nations assumed that fertility in developing countries would decline to half its initial level over a thirty-year period following the onset of a decisive decline. The three sets of United Nations projections are distinguished by different dates at which such a downward movement in fertility is assumed to begin (see chapter XV).

## 2. PROSPECTS IN AREAS WHERE FERTILITY IS NOW LOW

178. While the broad outlines of fertility movements within low-fertility countries are well known, attempts to pinpoint and assess the relative influence of specific economic and social factors on fertility have not yielded conclusive results. It is the general realization that fertility is ultimately an aspect of human behaviour and that, as such, economic and social factors conditioning it will be expressed in motivations of some sort, that has led modern investigators to more subtle approaches. The study of expected family size appears as one means of assessing the family's intentions in respect of childbearing. In view of the ease of obtaining and applying efficient contraceptive techniques in the advanced societies, such an approach has been thought to have merit for short-term projections, though in actual practice it has been found to have many limitations.<sup>363</sup>

179. Post-war movements suggest that uniformity of future fertility trends cannot be expected. According to

<sup>363</sup> See, for example, Ryder and Westoff, "The trend of expected parity . . ." (1967).

Biraben, moderately high fertility rates are a possibility in Western Europe.<sup>364</sup> On the other hand, in certain countries of Eastern Europe, experts have recently expressed concern regarding the low level of current and projected fertility.<sup>365</sup> Even where prevailing levels of fertility continue, short-term fluctuations may occur. The hypothesis has been advanced that, in the later stages of the spread of fertility control, the level obtaining in a country will temporarily tend to fall below any tenable long-term level. One basis for this hypothesis is that for a short time fertility will be depressed below its long-term level because birth restriction by different cohorts will be bunched in the same period. In addition, the members of certain cohorts would reduce fertility to an unusual degree.<sup>366</sup> According to Ryder, the fertility of industrialized countries is not expected to change much in the long run, but "improved ability to determine fertility will lead to greater sensitivity of response to instability in the environment, and therefore to the risk of fertility fluctuations of even greater amplitude . . . than we have seen in the recent past".<sup>367</sup>

<sup>364</sup> Biraben, "Evolution récente de la fécondité . . ." (1961).

<sup>365</sup> Regarding Hungary, see, for example, Szabady, "Születésszámunk nemzetközi és történeti megvilágításban" (1964); and his "Magyarország jövőbeli népességi perspektívái" (1964).

<sup>366</sup> Coale, "Introduction" (1960), p. 7.

<sup>367</sup> Ryder, "The character of modern fertility" (1967), p. 36.

## MORTALITY

1. Among the components of population change, mortality has historically played an important role in determining the growth of population. Following the Industrial Revolution, the death rate began a slow descent in the now developed countries of Europe, and later in areas of European overseas settlement, contributing to a gradually rising rate of population growth as fertility decline lagged behind. Recently in the world's developing countries mortality has fallen rapidly, accounting for the very rapid increase in population experienced by these countries, while their fertility levels remained relatively stable. Now that mortality has been reduced to moderate levels in most developing regions of the world, fertility will increasingly become the decisive factor in population growth. In addition to its role in determining numbers of population, mortality also exerts an influence on the age structure of the population, though its effect in this respect is much smaller than that of fertility (see chapter VIII, section B).

2. The health status of a population has an obvious bearing on mortality, and hence on population growth; moreover, its importance as a variable affecting the quality of the population is also recognized. Analyses of the health status of the population have generally been neglected in demographic research, however, largely because of the poor development of the data and techniques used in measuring health.<sup>1</sup> Far more is known about levels of mortality than about conditions of health and morbidity within the various countries. In the first place, the concept of health as a measurable variable is rather vague. Because of the difficulties involved in measuring the positive characteristics of health, the opposite concept of ill-health, or morbidity, is usually adopted as the object of study. Even this concept, however, does not lend itself to precise definition and measurement, since the delimitation between health and illness in a particular individual is frequently uncertain. In contrast, death is a clearly defined event, and Governments have generally adopted legal provisions for the registration of such events, even though in many countries such registration is incomplete in practice. No established procedure exists, on the other hand, for the reporting of illness. Generally, illnesses are reported only when they lead to admission to a hospital, or at least to a visit to a physician.

3. While mortality data are often used as indicators of health status, they may sometimes give an erroneous or distorted picture. In the developed countries which have achieved low mortality levels and where death

has become relatively uncommon after the first month of life and until old age, mortality and cause-of-death statistics have lost much of their value as indicators of morbidity. Thus, the need for morbidity statistics has become more apparent.<sup>2</sup> Because of the severe limitations of the more readily available types of data, such as hospital statistics, or industrial records of causes of absences from work, the trend has been increasingly towards the use of national sample surveys to collect data on the incidence of illness in the population.

4. The concept of societal responsibility for the health of the population, little dreamed of a century ago, has won gradual acceptance over time so that today nearly everywhere the reduction of disease and lowering of death rates are considered important tasks of government. Moreover, in a setting of growing interdependence among countries and with the gradual extension of international contacts and travel, Governments have sought collaboration in health matters. Such collaboration has gathered momentum since the establishment of the World Health Organization in 1946. The broad view of health stated in that organization's Constitution as "... a state of complete physical, mental and social well-being"<sup>3</sup> serves as a goal for eventual national attainment. In fact, the Constitution specifically states that "Governments have a responsibility for the health of their peoples which can be fulfilled only by the provision of adequate health and social measures".<sup>4</sup>

5. The continued effort to control disease and reduce mortality is a universally accepted government policy even in those developing countries where rapid population growth presents many serious problems. Aside from the important, and obvious, humanitarian considerations, the contribution that better health makes to economic development, for example, through increased labour productivity, should not be overlooked.<sup>5</sup>

6. Government policies relevant to health cover a wide variety of matters involving measures which directly or indirectly promote better health. Formal statements of health policies are not always easily accessible, although some are set forth in the development plans of certain countries.

<sup>2</sup> On the needs for morbidity data in developing countries, see Swaroop, "Study of morbidity in underdeveloped areas" (1959).

<sup>3</sup> World Health Organization, *Basic Documents* ... (1969), p. 1.

<sup>4</sup> *Ibid.*

<sup>5</sup> See Taylor, "Health and population" (1965), p. 477; Taylor and Hall, "Health, population and economic development" (1967), p. 3.

<sup>1</sup> Linder, "Health as a demographic variable" (1959), pp. 489-490.

7. Faced with many challenging health problems, Governments must select priority areas for action, bearing in mind limitations on their resources.<sup>6</sup> That these priorities differ greatly in developed and developing countries, owing to the very different nature of their pressing health problems, is evident from a few examples. Thus, in the Netherlands, where adequate curative health care has been provided for many years through compulsory insurance, government policy has placed increasing emphasis on preventive health measures and on rehabilitation of disabled persons which can result in important savings in social expenditures.<sup>7</sup> In the health service of the Soviet Union the stress is also on preventive medicine, and the development of an extensive network of dispensaries and clinics throughout the country has permitted the observation of healthy persons as well as the sick.<sup>8</sup> In contrast, certain developing countries such as India give high priority to the extension of health services to the rural villages to improve the balance of medical care between urban and rural areas.<sup>9</sup> Senegal's plan, adopted in 1961, emphasized health education in the rural areas and the expansion of rural health centres and mobile units, rather than new hospital construction.<sup>10</sup> In tropical Africa it has been suggested that sound health policy should be based on a balanced approach which might couple measures to improve the health of such high-risk groups as pregnant women and children with efforts to reduce morbidity and thus increase productivity among the working population. Progress in the latter area could be expected to lessen the strain produced by increased population growth.<sup>11</sup>

8. The complicated interplay of various biological, economic, social and cultural factors has an impact on the health of individuals and hence on the mortality levels of populations. Among these influences, a broad distinction is often made between those which are biological in nature, and not subject to change in the short run, and those which are environmental. This chapter is concerned mainly with the latter, and gives little attention to such factors as the genetic composition of the population, natural selection, and the susceptibility or resistance of population to endemic or epidemic diseases. Despite their obvious importance as factors affecting health and mortality, advances in medical knowledge and in the application of medical science in the prevention, diagnosis and treatment of disease are likewise not treated in detail, although a brief summary is included of outstanding medical discoveries which have contributed to the control of disease.

9. The emphasis in the present chapter is rather on the demographic, economic, social and cultural factors which affect mortality. Sex and age structure are the main demographic factors considered, since the crude death rate is influenced by the proportion of aged persons in the population, and by the ratio between the sexes, males generally having higher mortality than females in modern times. The economic and social factors which influence the level of mortality are numerous and of considerable complexity; they include, for example, occupation, educational level, nutritional standards, housing conditions, sanitation, public health services, medical services and the general level of living. Statistics on the levels and trends of mortality rates in different geographical areas and among different population groups, analysed in relation to known facts about the economic and social conditions of the various areas and population groups, make it possible to draw inferences regarding the factors which determine the rates. Because these factors are mutually interdependent, however, a satisfactory quantitative estimate of the influence of any one factor is very difficult to obtain. Thus, for example, the health of an individual is greatly influenced by his level of living, which is in turn partly determined by his education, and by such conditions as the state of the labour market and of the economy in general. Habits concerning personal hygiene which affect health are partly conditioned by an individual's level of living and education, but may also be influenced by the individual's cultural heritage and the prevailing social environment.

10. The known facts concerning levels, patterns and trends of mortality in different regions of the world are summarized in the following sections. Section A is concerned with general mortality levels and trends, section B with sex and age patterns, section C with foetal and infant mortality, section D with causes of death, and section E with mortality differentials among different regions and population groups. The next three sections of the chapter deal respectively with factors related to high mortality in the past, factors in mortality decline in developed countries, and factors related to mortality levels and trends in developing countries. A final section discusses prospects for future mortality change.

## A. Levels and trends of mortality

### 1. RECENT MORTALITY LEVELS

11. The crude death rate<sup>12</sup> is the most widely available index of mortality. It provides a measure of gross deletions from the population through death, and is also useful for giving a general idea of mortality trends within one area and for roughly classifying countries according to mortality levels. However, care must be exercised in its use for international comparisons, as it is greatly affected by the age structure of populations.<sup>13</sup> Age-

<sup>12</sup> The crude death rate is generally computed as the number of deaths in a year per thousand of the mid-year population.

<sup>13</sup> The anomalous situation may arise, for example, of a country with a high proportion of young people having a lower crude death rate than a country with an older population, although the age-

specific death rates,<sup>14</sup> standardized death rates,<sup>15</sup> and computations of expectation of life at birth<sup>16</sup> (or at another specified age) are measures which do not suffer from this deficiency and are often used to compare mortality levels between different countries or changes in mortality over time.<sup>17</sup>

12. Although satisfactory death registration data were available for only a little more than one third of the world's population around 1960,<sup>18</sup> sample surveys and other sources have provided a means of estimating approximate mortality levels for the different regions of the world. Table V.1 shows estimated crude death rates and expectation of life at birth for the period 1965-1970. Figures for the developing regions are subject to a considerable margin of error, since they depend in part on extrapolations of previous trends. For the world as a whole, the crude death rate was estimated at about 14 per 1,000 population for this period, but the rate was by no means uniform for the major regions. In the less developed regions of Africa, Asia and Latin America combined, the death rate was about 16, as compared with 9 for the developed regions as a whole. Among the developing regions, the crude death rate was highest in Africa (21 per 1,000 population) and lowest in Latin America (10); it was estimated at about 14 for East Asia and 17 for South Asia. Differences between developed regions in the

---

specific rates for most age groups may be greater in the former than in the latter. For a discussion of the limitations of the crude death rate, see United Nations, *Demographic Yearbook, 1966* ... (1967), pp. 1, 32.

<sup>14</sup> Number of deaths in a particular sex-age group per 1,000 mid-year population in the same sex-age group.

<sup>15</sup> Methods of standardization are discussed in the following works, among others. Woolsey, "Adjusted death rates ..." (1947); Karpinos and Chassan, "A note on standardized rates" (1949); Wolfenden, "On the theoretical and practical considerations ..." (1962); Kitagawa, "Standardized comparisons in population research" (1964).

<sup>16</sup> This measure of mortality, which is derived from the life table, represents the average number of years of life to which a group of newborn infants could look forward if they were subject to the same risks of death at each age as those prevailing in the population at the time period to which the life table refers. Methods of life table construction are contained in a number of works, including the following: Spiegelman, *Introduction to Demography* (1955), pp. 72-93; Stolnitz, *Life Tables from Limited Data* (1956); Barclay, *Techniques of Population Analysis* (1959), pp. 93-122; Mizushima, *Seimeihyo no kenkyu* (1963); Pressat, *Principes d'analyse* (1966). Calculation of a life table requires accurate statistics of deaths classified by age groups, as well as data on the numbers of population in each age group. Methods of life table construction have also been developed for use where vital statistics are lacking or unreliable. See Mortara, *Methods of Using Census Statistics* ... (1949), pp. 1-10; Arriaga, *New Life Tables for Latin American Populations* ... (1968), pp. 8-15. Systems of model life tables have also been developed for use where the basic data required for life table construction are unavailable. See United Nations, *Age and Sex Patterns of Mortality* ... (1955); ———, *Methods for Population Projections by Sex and Age* (1956); Coale and Demeny, *Regional Model Life Tables and Stable Populations* (1966); Ledermann, *Nouvelles tables-types de mortalité* (1969).

<sup>17</sup> The advantages of different measures of mortality for the purpose of measuring progress in public health are discussed by Dolejši, "K problému komplexního ukazatele ..." (1964), pp. 346-351.

<sup>18</sup> Even in some countries where birth registration is considered to be satisfactory, death registration data are inadequate, infant deaths in particular being frequently under-reported.

level of the crude death rate were much less pronounced than in the developing regions.

13. Within each of the developing regions there is also considerable variation in the level of crude death rates for individual countries. In Africa the number of deaths per 1,000 population during the early to mid-1960s ranged from about 9 in the small, atypical island of Mauritius to 30 or over according to surveys carried out in some countries of Western and Middle Africa. In the Latin American region, the crude death rate was as low as 7 per 1,000 in Puerto Rico, but rates above 20 have been estimated for Haiti and Bolivia. In Asia, very low crude death rates of 5-7 per 1,000 are found not only in the more highly developed countries in this region, such as Israel, Japan and the Ryukyu Islands, but also in several of the lesser developed countries. In contrast, crude death rates above 20 have been estimated for Indonesia, Iran, Laos and Nepal.<sup>19</sup>

14. It is noteworthy that some developing countries have attained death rates lower than those now prevailing in industrialized countries. However, if age structure of the population is taken into account, the mortality rates of the industrialized countries are, in general, lower. This paradox is explained by the higher proportion of older persons in the populations of the industrialized countries.<sup>20</sup>

15. The effect of differences in age structure on regional death rates has been demonstrated by comparing unadjusted crude rates for 1965 with rates standardized for age structure. Thus, the average crude death rate for the developing regions would be raised by three points—from 18 to 21 per 1,000—if the age structure of the population were the same as that of the developed regions. While the crude death rate for Latin America was only slightly higher than that of Europe in 1965, the less favourable mortality situation in the former region is apparent from the standardized rates, which were 14 and 19 for the two regions respectively.<sup>21</sup>

16. Another satisfactory measure of differences between the mortality levels of different populations is expectation of life at birth, since it is not affected by age structure of the populations. The regional estimates presented in table V.1 show that the peoples of the world who are economically deprived are also those with the shortest life expectancy. According to prevailing mortality conditions in the late 1960s, a person born in Northern Europe could expect to live nearly thirty years longer on average than a person born in Africa.<sup>22</sup> The gap in average life expectancy between Northern Europe and Asia was

---

<sup>19</sup> United Nations, *Demographic Yearbook, 1968* ... (1969), tables 3 and 18.

<sup>20</sup> For a fuller discussion of the effect of age structure on the crude death rate, see United Nations, *Population Bulletin of the United Nations, No. 6* ... (1963), p. 14.

<sup>21</sup> Macura and El-Badry, "Diversity or uniformity of demographic problems? ..." (1968), p. 204.

<sup>22</sup> The estimated average life expectancy in Africa of about 43 years suggests conditions of mortality not very different from those prevailing in the United States in the middle of the nineteenth century. Expectation of life at birth for white males around 1850 has been estimated at about 40 years, while for females it was lower. Jacobson, "An estimate of the expectation ..." (1957), p. 198.

TABLE V.1. ESTIMATED CRUDE DEATH RATES AND EXPECTATION OF LIFE AT BIRTH FOR MAJOR AREAS AND REGIONS OF THE WORLD, 1965-1970<sup>a</sup>

<sup>a</sup> For the developing regions the figures are estimates of the order of magnitude and are subject to a substantial margin of error.

more than twenty years and between Northern Europe and Latin America about twelve years. The range of expectation of life among the more developed regions is shown to be very narrow—from 65 years in Temperate South America to 72 years in Northern and Western Europe and in Australia and New Zealand. In addition to these regions, the remaining regions of Europe, Northern America, Japan and the USSR had achieved life expectancies of at least 70 years by the late 1960s.

17. Very significant inequalities in expectation of life at birth have been observed between populations within the developing regions. For example, during the period 1955-1960 average life expectancy among Central American countries is estimated to have ranged from 36-45 years in Haiti to 56-62 years in Costa Rica and Cuba, and

within South America it varied from 40-45 in Bolivia to 65-68 years in Uruguay.<sup>23</sup> Available information suggests a range of similar magnitude among Asian countries. The more meagre and less reliable statistics for Africa suggest somewhat greater uniformity in that continent, though expectation of life in Southern and Northern Africa is unquestionably above the average for the continent.

## 2. PAST TRENDS

18. Knowledge of the mortality conditions that prevailed in the now developed regions in the distant past is very incomplete, but it is clear that the life span was very short (see chapter II, section A). A life table for ancient Greece, prepared from burial inscriptions, indicates an average length of life of about 30 years around 400 B.C.<sup>24</sup> Estimates of life expectancy in various European countries from the thirteenth to the seventeenth century, based on fragmentary data, range from 20 to 40 years.<sup>25</sup> Mortality rates were very irregular at the time, for certain years being double or treble the long-range average. Such large variations in mortality rates were due to frequent outbreaks of epidemics (for example, plague and smallpox) and to great famines. Steady, if slow, improvements in conditions affecting mortality are indicated by the life tables for a number of European population groups during the eighteenth century, most of which show expectation of life at birth ranging from about 35 to 40 years.<sup>26</sup>

<sup>23</sup> Sauvy, "La population des pays ..." (1963), pp. 63-65. See also Somoza's studies of mortality in Latin American countries at varying dates around 1950-1960. Somoza, "Trends of mortality ..." (1965), pp. 222-226; and his "Levels and trends of mortality in Latin America ..." (1967).

<sup>24</sup> Valaoras, "The expectation of life in ancient Greece" (1936), pp. 403-407.

<sup>25</sup> The expectation of life in Geneva was estimated at about 21 years in the period 1561-1600 and about 26 years in the period 1601-1700. Bickel, "Early Swiss mortality tables" (1949), p. 359. A generation life table of males born 1426-1450 in England, constructed from the manuscript inquisitions *post mortem* in the Public Record Office, shows an expectation of life at birth of 33 years. Russell, "Demographic pattern in history" (1948), p. 404. In the first life table ever constructed, the expectation of life in the city of Breslau during 1687-1691 was found to be 33.5 years. Halley, "An estimate of the degree of mortality of mankind" (1693). Genealogical records for men in the ruling classes of Europe born during the period 1480-1579 indicate an expectation of life for the group of about 30 years. Peller, "Studies on mortality since the Renaissance" (1947), p. 79. The expectation of life at birth in the Normandy parish of Crulai in the period 1690-1750 was estimated at 32-33 years. Gautier and Henry, "La population de Crulai ..." (1958).

<sup>26</sup> The Swedish tables for 1755-1776 show an expectation of life at birth of 33.2 years for males and 35.7 years for females. French tables by Deparcieux, published in 1746, gave an expectation of life at birth of 37.5 for both sexes. The corresponding figure from the Carlisle tables, based on the experience of two parishes in Carlisle, England, during 1779-1787, is 38.7 years. Dublin, Lotka and Spiegelman, *Length of Life* ... (1949), pp. 35-36, 346-351. Dublin and his associates surmised from what evidence they could gather that in the United States at the end of the eighteenth century the life expectancy at birth was between 35 and 40 years. *Ibid.*, p. 41. Henry estimated life expectancy of the rural population of France to have been about 30-35 years during the eighteenth century and that of the urban population even somewhat lower. Henry, "The population of France in the eighteenth century" (1965), pp. 434-456.

19. Stolnitz has suggested that the average expectation of life at birth of some 40 years in "the West" (including Northern and Western Europe, Northern America and Oceania) in 1850 represents the maximum attained by that date in any major region.<sup>27</sup> Some privileged groups could claim a better record before 1850; for example, it has been estimated that the expectation of life at birth of members of the British peerage, after oscillating with a maximum of just over 38 years during the period 1550 to 1750, gradually increased between 1750 and 1850 until in the last quarter of this period the expectation of life was 52.1 years for males and 58.4 years for females.<sup>28</sup> Also, according to estimates by Henry, the citizens of Geneva enjoyed an expectation of life of just over 40 years as far back as the first half of the eighteenth century.<sup>29</sup> For national populations, however, the Scandinavian countries probably had the most favourable mortality experience at given points in time. For the latter two-thirds of the eighteenth century, the crude death rate averaged 26-29 per 1,000 in Denmark, Finland, Iceland, Norway and Sweden, which is low compared to the rates in other European countries at that time.<sup>30</sup> Expectation of life at birth exceeded 40 years for the first time in Sweden in the 1820s and rose to 55.7 years by the first decade of the 1900s.<sup>31</sup>

20. The period since the beginning of the nineteenth century, especially since 1850, has been an era of outstanding progress in the prolongation of human life. An idea of the extent of this progress in several developed countries is given by the data in table V.2, which shows average values of expectation of life at birth for the combined populations of six European countries and a state of the United States, beginning in 1840. The rate of improvement was slower during the nineteenth than during the twentieth century, and decennial increases in life expectancy were most remarkable during the two decades following the turn of the present century and in the years immediately after the Second World War.

21. In contrast with the trends in Northern Europe, Oceania and the United States, the decline of mortality had a comparatively late start in some other parts of Europe and the Soviet Union. For example, in Italy as late as 1871-1880 life expectancy at birth did not exceed

TABLE V.2. AVERAGE EXPECTATION OF LIFE AT BIRTH FOR SIX EUROPEAN COUNTRIES AND ONE STATE IN THE UNITED STATES, BOTH SEXES, 1840-1965<sup>a</sup>

SOURCES: For 1840-1930 data are adapted from Hart and Hertz, "Expectation of life as an index of social progress" (1944); and Valaoras, *Stichia viometrias ke statistikis* (1943), p. 190. Data for later years have been compiled from United Nations, *Demographic Yearbook 1967* ... (1968), table 29.

<sup>a</sup> The countries are: Denmark, England and Wales, France, Netherlands, Norway and Sweden; the state in the United States is Massachusetts.

<sup>b</sup> Arithmetic average of expectation of life at birth for each sex.

<sup>c</sup> Includes the entire United States.

<sup>d</sup> Five-year increase.

35 years, and a steady fall of mortality did not start before 1875.<sup>32</sup> The decline in mortality was faster in those European countries where it began later. For example, according to Stolnitz's data, the rise in expectation of life at birth in Austria in the first three decades of the twentieth century matched the rise in the so-called "Western" countries during a period roughly twice as long, beginning around 1860.<sup>33</sup> In European Russia, average life expectancy around 1896-1897 was only about 32 years—below the level for Sweden in 1760, and as late as 1926-1927, it was only 44 years in the Soviet Union as a whole. But over the next three and a half decades the USSR realized a gain of twenty-six years in life expectancy for males and females combined, so that the value for 1960-1961 was 70 years.<sup>34</sup> In Italy it took fifty-five years for the crude death rate to decrease from about 30 (around 1875) to about 15 (around 1930), whereas such a fall had taken about 150 years in France and Sweden and about 125 years in England.<sup>35</sup> Expectation of life in

<sup>27</sup> Stolnitz, "A century of international mortality trends ..." (1955), p. 27.

<sup>28</sup> Hollingsworth, *The Demography of the British Peerage* (1964), pp. 56-57. "The levels of mortality experienced by the aristocracy during the three and a half centuries from the Elizabethans to the present day were presumably always lower than obtained amongst the general population, except for the special effects of the two world wars in the twentieth century. ... While progress was enjoyed first by the few, and only later by the many it spread throughout the population comparatively fast once it had been initiated. The expectation of life of the general population born around 1846 in England and Wales was 41.6 years, and for those born around 1876 it was 48.5; the same expectations of life were applicable to the nobility in about 1752 and 1793, respectively, showing time lags of ninety-four and eighty-three years between the highest social class and the general population." *Ibid.*, pp. 67-68.

<sup>35</sup> Cipolla, "Four centuries of Italian demographic development" (1965), pp. 579-580.

Greece, which is estimated to have been about 36 years in the 1860s, increased only gradually in the latter part of the nineteenth and early twentieth centuries; after 1920, however, improvement was much more rapid, and life expectancy increased from about 45 years in 1920-1924 to 65 years in 1955-1959.<sup>36</sup>

22. Trends in crude death rates in thirty developed countries from 1906 to 1969, and in ten developing countries from 1920 to 1969, are shown in tables V.3 and V.4 respectively. It is seen that during this period the most rapid improvements in mortality were registered in Eastern and Southern Europe, in the USSR, and in

countries of Asia and Latin America, rather than in those regions where mortality decline began relatively early. In nearly all countries in the former regions, mortality rates decreased by at least one-half since the early part of the century, and, in some cases, by as much as four-fifths. Some of the largest declines were registered by developing countries; for example, in Singapore, the crude death rate dropped from about 30 to 5 per 1,000 between 1920 and 1969, in China (Taiwan), from 26 to 5, and in Mauritius from 32 to 8. Changing age structure, as well as changing mortality conditions, contributed to these rapid declines, since, with fertility remaining relatively stable, the age pattern of mortality decline experienced by the developing countries has tended to increase the proportion of population in the younger age groups.

<sup>j</sup> Two-year average.

23. Statistics for most of the developing countries in table V.4 show that, while some improvements in mortality conditions were taking place in the 1920s and 1930s, the most rapid fall in mortality levels has unquestionably occurred after the Second World War. In Mexico, for example, the crude death rate was still as high as 22 per 1,000 in the early 1940s, but by the mid-1960s it had fallen to about 10. Fairly similar trends are observed in Ceylon, Chile and Malaysia. On the other hand, mortality decline seems to have begun earlier in the Caribbean islands of Jamaica, Puerto Rico, and Trinidad and Tobago than in most of the developing countries of Asia and Latin American for which trend data are available.

24. Life tables of satisfactory quality available for several developing countries also illustrate the fact that mortality has been declining at a faster pace in these countries in recent decades than was the case when the now developed countries had similar levels of mortality. In Trinidad and Tobago, average life expectancy rose from 38.8 to 61.4 during the thirty-four years from 1920-1922 to 1954-1956, whereas Sweden required 110 years, from 1810 to 1920, to accomplish the same feat.<sup>37</sup> Stolnitz provides evidence that survival trends in Guyana, Jamaica and Trinidad between the 1920s and the 1940s were equal to achievements for which the western developed countries required over half a century.<sup>38</sup> Ceylon gained twenty-eight years in life expectancy during the thirty-three years following 1921; more than one-quarter of this gain occurred during the seven years between 1947 and 1954.<sup>39</sup> Taiwan gained about twenty years in life expectancy from 1936-1941 to 1959-1960.<sup>40</sup>

25. Average life expectancy at birth in Puerto Rico, which was estimated at about 38 years in 1910, had risen to only 40.6 years by 1930, and to 46.0 years by 1940, at which time it was seventeen years less than in the United States. The average increase of 1.5 years annually during the next decade is one of the fastest rates of increase ever recorded. Progress continued during the 1950s, though at a less rapid pace, and average expectation of life by 1960 reached 69.4 years, a figure only negligibly below that for the United States in the same year.<sup>41</sup>

26. Comparisons of Chilean mortality experience with that for selected European countries also illustrates how mortality differences between developed and developing countries have been contracting. From 1920 to 1960 average life expectancy for males and females combined increased from 31 to 57 years, or a total of twenty-six years.<sup>42</sup> Subtraction of these values from the estimated average life expectancy of developed countries in table V.2 shows that the advantage held by the latter countries over Chile was reduced from twenty-seven to fifteen years.

Miró examined values of average life expectancy for twenty Latin American Republics at two recent dates in the 1940s and the 1950s and found that life expectancy had been extended greatly in all countries, but that the improvements had been most noteworthy in places where expectation of life at birth had previously been lowest.<sup>43</sup>

27. The developing countries which have satisfactory data for studying mortality trends are not representative of the populations of these regions as a whole, and there remain wide gaps in knowledge of mortality levels and trends. It is reasonably certain that high mortality and low expectation of life were the rule in these areas well into the twentieth century.<sup>44</sup> In Asia, data are almost totally lacking for several countries with very large populations, and for other large populations trend data are very uncertain. In a span of approximately forty years, from 1891-1901 to 1931-1941, it has been estimated that British India realized a gain of only about eight years in average life expectancy, from 24 to 32 years.<sup>45</sup> However, official Indian life tables for 1951-1960 showed an acceleration in improvements in mortality conditions, with life expectancy for both sexes combined increasing to 41 years.<sup>46</sup> Although Pakistan experienced a gain of about six years in life expectancy between 1951 and 1960-1965,<sup>47</sup> its estimated level of only 40 years places it, along with India, at about the level that developed western countries had achieved in 1840 (table V.2).

28. Except for the island of Mauritius in the Indian Ocean, no adequate data exist to study mortality trends for countries in the African region. There is some evidence of a relatively slow, though continuous rise in average life expectancy in Egypt; by 1959-1961 the level is estimated to have reached 51.6 years for males and 53.8 years for females. This represents a gain of sixteen years for males and twelve years for females over the levels estimated for 1936-1938.<sup>48</sup> Among the Coloured population of South Africa a gain in life expectancy of about seven years—from 40 to 47—is estimated to have been achieved between 1936 and 1951.<sup>49</sup>

29. In summary, mortality differences between developed and developing regions appear to be getting smaller, as a result of the recent important declines in the latter

<sup>43</sup> Miró, "The population of Latin America" (1964), pp. 38-39. See also Sauvy, "La population des pays d'Amérique latine" (1963), pp. 49-64; Pan American Health Organization, *Health Conditions in the Americas, 1961-1964* (1966), pp. 9-10.

<sup>44</sup> It has been estimated, for example, that the average length of life of slaves in Guyana between 1820 and 1832 was under 23 years, implying a crude death rate of about 40 per 1,000 population, and that there was little improvement in the mortality experience of that country in the years between manumission and the end of the nineteenth century. Roberts, "A life table . . ." (1952), p. 243.

<sup>45</sup> Davis, *The Population of India and Pakistan* (1951), p. 36.

<sup>46</sup> United Nations, *Demographic Yearbook, 1964* . . . (1965), p. 620. According to a study by Visaria, infant and child mortality were underestimated in the official life tables. His estimates show life expectancy at birth rising from about 33 years in 1941-1951 to 37.4 years in 1951-1961. Visaria, "Mortality and fertility in India . . ." (1969), pp. 111-112.

<sup>49</sup> Stolnitz, "Recent mortality trends . . ." (1965), p. 128.

regions. Thus, world mortality conditions appear to be approaching the completion of the circle; prior to the historical decline of mortality in the now developed countries, the level had probably not varied very much between regions. Mortality trends that accompanied the development of the West then gave rise to inequities in average length of life. With the improvements in the techniques of controlling disease in developing countries since the Second World War, these differences have substantially decreased, though in some regions, particularly in Africa, the gap between prevailing death rates and those in developed regions is still very wide.

## B. Sex and age patterns of mortality

30. In nearly all countries having reliable statistics there are notable inequities in mortality between males and females subjected to the same general environmental conditions. Though there are a few exceptions, females now usually have an over-all advantage, as is seen in recent data on average life expectancy at birth for each sex. Improvements in health conditions which have brought life expectancy to high levels in most of the world's developed regions appear to have benefited females more than males, with a consequent widening of the mortality gap between the sexes.

31. The incidence of death, of course, varies greatly with age, and long-term improvements in mortality have been found to affect different age groups to a different extent. Without statistics of deaths classified by sex and age groups, it would not be possible to disengage the effects of social and economic factors affecting mortality from those of the sex and age composition of the population in which the deaths occur. Reasonably reliable statistics of this type are available for less than half of the world's population, however, their coverage being particularly sparse in the economically less developed regions.

### 1. SEX DIFFERENCES IN MORTALITY

32. Expectation of life at birth is almost universally higher for females than for males, both in developed countries with low mortality and in developing countries with higher mortality levels. Ceylon, India and Pakistan appear to be the exceptions in recent years to the predominant pattern of higher female life expectancy. According to life tables for these countries, expectation of life at birth for males exceeded that for females by 0.5 years in Ceylon (1962), 1.3 years in India (1951-1960) and 2.7 years in Pakistan (1962-1964).<sup>50</sup> Available data suggest that higher female than male mortality may also be found among several other populations in Asia and Africa, but the evidence is less clear than in the case of the three

countries mentioned above.<sup>51</sup> Moreover, other instances of higher female than male mortality may occur in those parts of the world for which no reliable documentation is available.

33. In countries of low mortality, not only is the expectation of life at birth higher for females than for males, but death rates at each age are usually higher for males than for females.<sup>52</sup> The same pattern does not hold true, however, for the developing countries, where mortality levels are generally higher. Numerous instances are found of higher female than male mortality at particular ages, despite the higher overall male mortality which characterizes most of these countries. While infant mortality for females is almost invariably less than that for males,<sup>53</sup> at ages 1-4 years recorded death rates are higher for girls than for boys in such countries as Mauritius, Réunion, the United Arab Republic, Costa Rica, Guatemala, Mexico, Puerto Rico, and China (Taiwan), as well as in Ceylon, India and Pakistan.<sup>54</sup> Excessive female mortality in the reproductive ages, as well as some younger ages, was a common occurrence among the populations of Northern and Western Europe before 1920, and even later in Eastern and Southern Europe.<sup>55</sup> As late as 1930 in Japan mortality was higher for females than for males in the age span from five to forty years.<sup>56</sup> In recent years, however, such a differential appears only among some populations in the world's developing regions. For example, statistics for the 1960s show higher female than male mortality still persisting at the ages of

<sup>51</sup> A life table for the Asian population of South Africa (1950-1952) showed a higher life expectancy for males than for females, as did life tables based on sample survey data for Cambodia (1958-1959) and Upper Volta (1960-1961). United Nations, *Demographic Yearbook*, 1967 ... (1968), table 29. See also Soda, "Trends of mortality in Asia and the Far East" (1967), p. 362. It has been suggested that the high sex ratio of the population enumerated in the 1966 census of Iran (107 males per 100 females) may be indicative of higher female than male mortality. El-Badry, "Higher female than male mortality in some countries of South Asia ..." (1969), p. 1239.

<sup>52</sup> An exception is Yugoslavia, where higher female than male mortality at ages 1-4 years has persisted in the period following the Second World War. Plavec, *Smrtnost stanovništva u Jugoslaviji* ... (1967), pp. 13-14.

<sup>53</sup> Albania and the United Arab Republic were among the very few countries recently reporting higher infant mortality for females than for males. United Nations, *Demographic Yearbook*, 1967 ... (1968), table 16. In some areas of Yugoslavia, post-neonatal infant mortality was found to be lower among males than among females. Tasić et al., *Smrtnost odojčadi u Jugoslaviji* (1966), pp. 48-49.

<sup>54</sup> United Nations, *Demographic Yearbook*, 1967 ... (1968), table 21. Excess female mortality at the ages of early childhood has sometimes been attributed to parental preferences for male children and consequent neglect of females. Jain, "Actuarial report—1951" (1954), p. 26. See also Robinson, ed., *Studies in the Demography of Pakistan* (1967), p. 11. It has been noted, however, that unless reported infant mortality rates, which show an excess of male mortality, are so erroneous as to reverse the truth, they pose a challenge to the argument that in certain societies female infants are given less attention than males on cultural grounds. El-Badry, "Higher female than male mortality in some countries of south Asia ..." (1969), p. 1242.

<sup>55</sup> Stolnitz, "A century of international mortality trends, II" (1956), pp. 23-24; Pascua, "Recent mortality-trends in areas of lower death-rates" (1955), p. 261.

<sup>56</sup> Pascua, "Recent mortality-trends in areas of lower death-rates" (1955), pp. 262, 280.

<sup>50</sup> For Pakistan, see Yusuf, "Abridged life tables for Pakistan ..." (1967), p. 541; for Ceylon and India, see United Nations, *Demographic Yearbook*, 1967 ... (1968), table 29. Sarkar's life tables, computed from death rates based on census data adjusted for under-enumeration, give a higher life expectancy for females than for males. See his *The Demography of Ceylon* (1957), pp. 120-121. On sex differentials in mortality in the Punjab, see Gordon, Singh and Wyon, "Causes of death at different ages ..." (1965), pp. 6, 11.

<sup>c</sup> For Federal Republic of Germany.

peak fertility in such countries as Mauritius and West Malaysia. Moreover, in Ceylon, India and Pakistan, particularly large differentials between the sexes occur in the reproductive ages owing to higher maternal mortality.<sup>57</sup>

34. Recent life tables show that in the more developed countries, the advantage that females have over males in average life expectancy at birth is generally greater than in countries of the developing regions. In Northern America, Australia, the Soviet Union and many European countries, the life expectancy at birth is 6-8 years greater for females than for males, whereas in countries of the developing regions, the female advantage is usually less than five years.<sup>58</sup> Moreover, long-term mortality declines have generally increased the female advantage in expecta-

tion of life at birth.<sup>59</sup> Such a trend is seen in table V.5 which compares life expectancy values at the beginning of the century and at the mid-1960s for eighteen developed countries. Females are shown to have increased their longevity advantage over males in each of these countries, though if percentage differences, rather than absolute differences in life expectancy values for the two sexes are compared, a widening of the sex differential is barely discernible in Denmark and Sweden. In a study of recent mortality trends in Eastern Europe it was found that in six of nine countries both the percentage and absolute differences between the life expectancy values for the

<sup>57</sup> For India, see India, The Cabinet Secretariat, National Sample Survey, *Tables with Notes on Differential fertility ...* (1968), p. 15. For Pakistan, see Seltzer, *Benchmark Demographic Data for Pakistan ...* (1968), pp. 21-22, 39. For Ceylon, Mauritius, and West Malaysia, see United Nations, *Demographic Yearbook, 1967 ...* (1968), table 21.

<sup>58</sup> United Nations, *Demographic Yearbook, 1967 ...* (1968), table 29. See also Stolnitz, "Recent mortality trends ..." (1965), pp. 136-137.

<sup>59</sup> Studying data for fourteen European countries, Chasteland observed that, with only one exception, male excess mortality had increased during the first half of the twentieth century. See his "Evolution générale de la mortalité en Europe occidentale ..." (1960), pp. 82-83. Using age-adjusted death rates computed for nineteen low-mortality populations, Spiegelman showed that the average male-to-female ratio rose from 1.2 in 1930 to 1.3 in 1950 and 1.5 in 1960. Spiegelman, "Recent mortality in countries of traditionally low mortality" (1967). See also Federici, "Osservazioni sull'evoluzione temporale di alcune caratteristiche della mortalità ..." (1954); Naddeo, "Caratteristiche strutturali della mortalità ..." (1965); George, "Mortality trends in Canada, 1926-1965" (1967), p. 987.

two sexes were greater in the 1960s than they had been earlier in the period following the Second World War.<sup>60</sup>

35. Age-specific death rates for European countries for recent dates show that the largest percentage differences between the sexes generally occur in the twenties, owing to the greater risk of accidental death to which young men are exposed. The excess mortality of men then falls and reaches a low level between thirty and fifty years, after which there is a rise to a second peak usually between fifty and sixty-four years.<sup>61</sup> Various studies have examined male excess mortality either in terms of broad age groups only or in terms of absolute rather than percentage differences between male and female rates, and in such cases the greatest differences have usually been observed in the late middle ages. Thus, Spiegelman, studying 1960 death rates for broad age groups, found that in fourteen of nineteen countries the female advantage in mortality was greatest at ages 45-64 years.<sup>62</sup> In some studies sex differences in mortality have been analysed in terms of expectation of life at various ages—a measure which reflects differences in male and female survival rates at all older ages. For developed countries, these figures have generally shown the greatest differential at birth, with decreasing differences at advancing ages. By age sixty the remaining sex differential in life expectancy is generally quite small; for example, it averaged 2.0 years in countries of Northern and Western Europe in the 1940s.<sup>63</sup> Somewhat greater sex differences in life expectancy at this age are shown for European countries in later years.<sup>64</sup>

36. Long-term trend data for European countries show that females have increased their mortality advantage over males in all age groups since the early part of the century, with the greatest relative increases occurring at adult ages. Thus, in the European countries studied by Chasteland, male mortality at ages 15-40 on average exceeded that for females by about three per cent around 1900, but by about 50 per cent at mid-century. A large increase in male excess mortality was also reported at

ages 40-60 years.<sup>65</sup> In recent decades a particularly marked widening of the sex differential has been observed at ages 15-24 years, both in England and Wales<sup>66</sup> and in the United States. The rising incidence of motor vehicle deaths which affect males disproportionately has been an important factor in this trend. Widening sex differentials were also pronounced at ages 45-64 years in the United States, because of a rising death rate from heart disease and malignancies among males, at the same time that the female death rate resulting from these diseases was declining.<sup>67</sup>

37. What few reliable data there are on long-term changes in life expectancy in developing countries suggest that the trend toward a widening sex differential is less uniform than in the developed countries. Data for six countries in Latin America and three in Asia covering four decades preceding 1960 are shown in table V.6. In Chile and Puerto Rico the gap between male and female average life expectancy at birth has widened over the period from 1920 to 1960 both in absolute and percentage terms, while in Guyana, Jamaica, Mexico and Trinidad and Tobago, the sex differential in years of life expectancy was greater in 1960 than in earlier years, but the percentage gains were nearly equal for the two sexes.<sup>68</sup> In China (Taiwan) between the late 1920s and 1960, average life expectancy for females has exceeded that for males by a nearly constant amount of over four years.<sup>69</sup>

38. In Ceylon, where the official life tables show an excess female mortality, the gap between life expectancy for males and females has narrowed from 2.0 years in 1920-1922 to 0.5 years in 1962. During this forty-year period life expectancy nearly doubled, rising from 32.7 to 61.9 years for males and from 30.7 to 61.4 years for females. In India, where sex differences in mortality are also at variance with the normal pattern, life tables for 1941-1950 and 1951-1960 show a relatively greater gain for males, and hence a widening of the sex differential.

39. The available information may be summarized in Stolnitz's conclusion that mortality differentials tend to be less favourable to females in non-industrial and developing regions of the world than in the industrially advanced countries, and that in the developed countries the

<sup>60</sup> Szabady, "A kelet-Európai szocialista országok halandósági trendjei ..." (1968), p. 960. relative survival chances of males are becoming increasingly prejudiced under conditions of industrialization.<sup>70</sup> A belief prevailing some three or four decades ago that the growing participation of women in economic activities would lead towards equalization of mortality between the two sexes has not become a reality.<sup>71</sup>

## 2. AGE DIFFERENCES IN MORTALITY

40. The typical age-specific mortality curve in countries of high mortality is roughly U-shaped, the left-hand value of the U representing the high mortality of infancy and the right-hand value corresponding to the mortality of old age. As expectation of life increases, infant mortality falls much faster than mortality at old age, and the curve therefore assumes more of a J-shape. In addition, its base becomes broader, indicating that low mortality rates extend over a larger number of age groups. Some typical modifications of these patterns are discussed below. Age-specific death rates for a few selected countries are shown in table V.7.

41. An especially wide range of death rates throughout the world is found at ages 1-4 years. In fact, even among developing countries, rates vary widely at these ages. Thus, in China (Taiwan), the death rate at ages one to four was only about 4 per 1,000 and in Mauritius only about 7 per 1,000 in the mid-1960s, while in Guatemala it was about 28, and according to sample survey results, 45 in India (1958-1959), and around the same level in Dahomey and Togo in 1961.<sup>72</sup> In certain populations there appears

to be a very high level of mortality at the ages of young childhood in relation to the general level of mortality. A striking example is provided by the Cocos-Keeling Islands, where the chance of dying between ages one and four was as great as the chance of dying in infancy for boys, and considerably greater for girls.<sup>73</sup> For countries with high childhood mortality rates the left side of the U does not fall so steeply as in countries where early childhood mortality is largely concentrated in infancy. Despite impressive reductions in childhood mortality in some developing countries, in many of them half or nearly half of all deaths still occur among children of pre-school age.<sup>74</sup>

42. Some developing countries are characterized by relatively light mortality at the younger ages and comparatively heavy mortality at the older ages. Such a pattern has been observed, for example, in Mauritius, especially among the male population,<sup>75</sup> and may reflect impaired health of persons in the older age groups who had survived arduous health conditions when they were young.

43. Improvements in health conditions in modern times have brought important mortality declines at all ages, but the per cent reduction has been most spectacular in the case of children and young adults, having been progressively less with increasing age. In the words of a United Nations study, "... more has been accomplished

in eliminating premature death than in lengthening the life-span of persons who survive beyond middle age." <sup>76</sup>

44. From table V.8 it is seen that death rates at ages 1-4 and 5-14 in each of several countries of Northern and Western Europe declined by 85 per cent or more during the seventy-year period extending from the last quarter of the nineteenth century to the middle of the twentieth. Reductions in infant mortality, not depicted in the table, were only slightly less impressive. <sup>77</sup> It has been estimated

<sup>76</sup> United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), p. 53. It has been shown that different statistical measures lead to different conclusions concerning the relative mortality improvements achieved by the various age groups. Stolnitz found that while mortality changes at older ages are comparatively limited if trends in age-specific mortality rates are examined, this is not the case when per cent increases in survival ratios or life expectancy are used as the basis for analysis. Stolnitz, "A century of international mortality trends ..." (1956), pp. 36-40. Several other writers who have analysed age patterns of mortality change in terms of survival ratios have also demonstrated that the long-term per cent gains have been greatest at the youngest and oldest ages and relatively small in between. Hermalin, "The effect of changes in mortality rates ..." (1966); Keyfitz, "Changing vital rates ..." (1968); Coale, "The effect of decline in mortality ..." (1956). The latter authors were mainly interested in the effect of mortality decline on age structure, a subject discussed in chapter VIII.

<sup>77</sup> See Norway, Statistisk Sentralbyrå, *Dødeligheten og dens årsaker* ... (1961), pp. 216-223. Long-term trends in age-specific death rates in various other countries have displayed some of the same features. In the Soviet Union and the United States mortality fell at all ages during the twentieth century, though the proportionately greatest decreases were in early childhood and the proportionately smallest at the oldest ages. United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), pp. 53-54. In Poland it is estimated that the death rate at ages 1-4 fell by 95 per cent during the first sixty years of the present century, while the infant mortality rate fell by two-thirds. Padowicz, "Evolution de la mortalité d'après les tables polonaises de mortalité" (1963), p. 726. For Germany, see Freudenberg, "Grundzüge der Sterblichkeitsentwicklung nach dem Alter ..." (1955). For Hungary, see Peter, "Changes in the age structure of mortality in Hungary" (1963). For Spain, see Villar-Salinas, "Tendencia de la mortalidad en España" (1955).

that the largest reductions in mortality during childhood occurred at about age three in most European countries, and the minimum mortality rate, which formerly occurred at about the fifteenth year of life, gradually moved towards a younger age. <sup>78</sup> Past forty-five years of age, the long-term declines fell off sharply for each sex with increasing age. At ages over seventy-five years, the per cent decreases in death rates were slight compared with those for younger age groups. <sup>79</sup>

45. For countries having a long series of reliable data, some time lags are apparent in the onset of mortality decline at different ages. Thus, in Sweden death rates for infants, children and young adults showed some improvement as early as the first half of the nineteenth century, whereas mortality at ages beyond forty-five years was not lowered until the latter half of the nineteenth century. <sup>80</sup> In England, mortality at ages between five and twenty-five years started declining before 1870, and substantial decreases had occurred at ages twenty-five to forty-five years by the end of the century. On the other hand, decisive improvements in infant mortality and mortality at the older ages did not take place before the beginning of the twentieth century. <sup>81</sup> In France there was apparently no improvement in death rates for males aged fifty years and over until as recently as 1936. <sup>82</sup>

46. Since the Second World War, trends in age-specific death rates in various European countries and in Northern America, Australia and New Zealand have followed patterns generally in line with previous long-term trends. <sup>83</sup> A significant feature in a number of these

<sup>78</sup> France, *Statistique générale, Evolution de la mortalité* ... (1941), p. 64.

<sup>79</sup> See Pascua, "Evolution of mortality in Europe during the twentieth century" (1950), pp. 59-60. On mortality changes at the older ages see Vincent, "La mortalité ..." (1951); Spiegelman, "Recent trends in mortality at the older ages in countries of low mortality" (1963); ———, "An international comparison of mortality rates at the older ages" (1955).

<sup>80</sup> United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), pp. 53-54. Anderson's analysis stresses the substantial mortality decline experienced at middle and older ages in Sweden between 1841-1850 and 1891-1900. See his "Age-specific mortality in selected Western European countries ..." (1955), pp. 242-243.

65 and over .....	22	24	27	25	39		

SOURCE: Computed from data in various issues of the United Nations, *Demographic Yearbook*.

countries, however, has been the increase in mortality rates for males in age groups over fifty or fifty-five years. The most pronounced reversals of previous downward trends have occurred in the Federal Republic of Germany, the Netherlands and Norway, where increases of 20 per cent, 15 per cent and 11 per cent, respectively, were recorded between 1950 and 1960 in the death rate for males aged sixty to sixty-four years. Some rise in death rates among males in late middle age or older has also been recorded in Austria, England and Wales, Northern Ireland, Scotland and the United States. These trends in part reflect an increase in deaths from cardio-vascular diseases, which could not be offset by further declines in mortality from infectious diseases, in view of the low levels of the latter which had already been reached. In some countries, recent upward trends may also be linked to impaired health of the cohorts most affected by hardships suffered during the Second World War.<sup>84</sup> In Japan there has been a recent retardation of the decline of mortality from infectious diseases among middle-aged males and relative stability in the rates from cancer and cardio-vascular illnesses.<sup>85</sup>

47. Representative data which would permit a similar assessment of changing age patterns of mortality in the developing regions are not available. For the few developing countries with relatively good statistics on age-specific mortality, it appears that the large declines since the Second World War have benefited adults up to about age thirty-five as much or more than they have benefited young children. Thus, of the seven countries for which trend data are shown in table V.9, only China (Taiwan)

shows a pattern more nearly like that of developed countries, wherein the percentage declines in mortality rates for children aged 1-4 years and 5-14 years exceed those of the next higher age groups by considerable amounts. In the other countries, declines of about two-thirds or more in death rates at ages 15-34 compare favourably with the improvements recorded at younger ages.<sup>86</sup> In Mauritius, an exceptional rate of progress has been noted at ages 15-34 years between 1944 and 1957,<sup>87</sup> and in Jamaica between 1943 and 1960, improvements were substantially greater at ages 5-34 years than among younger children, though during the first stages of mortality decline in Jamaica (beginning after 1921), the biggest percentage declines had occurred among children 2-4 years of age.<sup>88</sup> According to Sarkar's analysis of long-term trends in Ceylon, the greatest mortality declines in the first four and one-half decades of the century occurred among young adolescents,<sup>89</sup> while the spectacular post-war decline was shared in nearly equally by age groups up to forty-five years. In Chile, between 1940 and 1960, the drop in the infant death rate lagged behind that in all other age groups up to forty-five years.<sup>90</sup> Relatively little improvement was realized in the infant death rate in Western Malaysia between 1947 and 1957, while a two-thirds decline—the largest for any age group—occurred for children 5-9 years.<sup>91</sup>

### C. Foetal and infant mortality

48. Owing to the heavy wastage of life that occurs during pregnancy and in the first year after birth, special importance is given to the study of foetal and infant mortality, apart from analyses of general mortality levels and trends. The period between conception and the end of the first month of life is a particularly hazardous one,

<sup>84</sup> Biraben *et al.*, "La situation démographique ..." (1964), pp. 464-466; United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), pp. 54-57; Koller, "Trends of mortality in adult and old age" (1966); Légaré, "Mortality at age forty-five and over ..." (1967). The impact of war conditions on the health of the population in Czechoslovakia was studied by Blaha *et al.*, *Následky války na lidském zdraví* (1966). Higher mortality rates were found among population groups which had been subjected to conditions of stress during the war as compared with population groups not so affected. Caffin observed that the rise in mortality rates for men above sixty years of age between 1933 and 1947 might have resulted from a deferment of deaths, if the numbers deferred decreased in successive ages. Caffin, "Increases in recent ..." (1957), pp. 295-297.

<sup>88</sup> Roberts, "A note on mortality in Jamaica" (1950), p. 72.

<sup>89</sup> Sarkar, *The Demography of Ceylon* (1957), p. 118.

<sup>90</sup> See table V.9 and United States, National Center for Health Statistics, *Recent Mortality Trends in Chile* (1964), pp. 4-5.

<sup>91</sup> Saw, "Postwar mortality trends in Malaya" (1967), p. 576.

as the foetus and young infant are subject to heavy mortality arising from genetic factors or from damage occurring during gestation or birth. After the first month of life, non-biological factors, including diseases arising from inadequacies in care and feeding, as well as those related to more general environmental conditions, predominate as causes of death.

49. For purposes of analysis, the pre-natal and post-natal periods have been further sub-divided, taking into consideration the availability of statistical data as well as the nature of the factors exercising the main influences on mortality. The pre-natal phase has generally been divided to distinguish between early, intermediate, and late foetal deaths—the dividing points being set at twenty and twenty-eight weeks gestation, respectively. Little is known of the extent of foetal deaths in the early periods of pregnancy, since the collection of adequate data on such events is a difficult, if not insoluble, task, even in countries with well developed statistical systems.<sup>92</sup> That early losses are thought to be considerable is indicated by Valaoras's estimate that between one-fourth and one-third of all gestations are terminated prematurely prior to the twentieth week of pregnancy.<sup>93</sup> Data on late foetal deaths (stillbirths), which occur after the twenty-eighth week of pregnancy, are widely available, at least in the developed regions, but international comparison is seriously hampered both by under-registration of events and by the use of differing definitions and methods of reporting.<sup>94</sup>

50. Mortality during the first year of life is frequently divided into neonatal mortality, namely that occurring in the first month of life<sup>95</sup> and post-neonatal mortality, that occurring during the remainder of the first year. The importance of identifying separately early neonatal mortality, or that occurring in the first week of life, has also been recognized.<sup>96</sup> The distinction between neonatal and post-neonatal mortality serves roughly to separate the endogenous and exogenous components of infant mortality which reflect the influence of biological and environmental factors, respectively, and require different

kinds of efforts to bring them under control.<sup>97</sup> In order to obtain a more refined measure of endogenous and exogenous mortality, formulae have been devised to be applied to the conventional data on age at death.<sup>98</sup>

51. As a result of the marked progress made by industrialized countries in controlling mortality due to environmental factors, attention has been increasingly focused on neonatal mortality, which has proved more difficult to reduce. Also within the past few decades there has been a trend towards broadening the study of mortality occurring soon after birth to include as well that occurring in the latter part of the pre-natal period. The idea of combining stillbirths and early neonatal deaths into a single statistical unit, the so-called "perinatal" mortality, was introduced in the 1940s,<sup>99</sup> the justification being that the factors underlying both of these types of mortality are very similar, and differ from the factors responsible for mortality later in infancy. Data on perinatal mortality, moreover, have the advantage of eliminating some of the problems of comparability in the statistics for either stillbirths or neonatal deaths caused by different definitions and registration procedures.<sup>100</sup>

## 1. STILLBIRTHS AND PERINATAL MORTALITY

52. In 1960-1964 reported stillbirth ratios in the developed regions ranged from a low of near 10 per 1,000 live births in Czechoslovakia to near 30 in Portugal, the average being 13-14.<sup>101</sup> The incidence of stillbirths is believed to be much higher in the developing regions, though few countries have adequate data on the subject. Two countries with relatively satisfactory data—Trinidad and Tobago and Mauritius—reported stillbirth ratios of 27 and 66, respectively, in 1960-1964.<sup>102</sup> The stillbirth

<sup>92</sup> See, for example, Peller, "Mortality, past and future" (1948), pp. 410-411; Lessof, "Mortality in New Zealand ..." (1949); Maruyama, *Nyuji Shibo (II)* ... (1957).

<sup>93</sup> See Bourgeois-Pichat, "Evolution récente de la mortalité infantile" (1964), p. 422. See also his "An analysis of infant mortality" (1952). In principle, it should be possible to distinguish between endogenous and exogenous mortality directly on the basis of cause-of-death statistics, but in practice this is difficult because of the unsatisfactory quality of the latter.

<sup>94</sup> Peller, "Mortality, past and future" (1948), pp. 410-412. See also Bourgeois, "De la mesure de la mortalité infantile" (1946). Peller recommended that perinatal mortality should include stillbirths and deaths during the first week of life. Peller, *Quantitative Research in Human Biology and Medicine* (1967), p. 146. The International Conference for the Eighth Revision of the International Classification of Diseases in 1965 endorsed a proposal to define the perinatal period as extending from the twenty-eighth week of gestation to the seventh day of life. World Health Organization, *Manual of the International Statistical Classification of Diseases* ... (1967), p. xxvii.

<sup>100</sup> For example, in several countries infants dying before registration of birth are classified as stillbirths and are excluded from the count of infant deaths and live births. Perinatal mortality is independent of such statistical variations. See Bourgeois-Pichat, "An analysis of infant mortality" (1952), pp. 12-14; Peller, *Quantitative Research in Human Biology and Medicine* (1967), p. 145; Valaoras, "Refined rates ..." (1950), p. 253.

<sup>101</sup> United Nations, *Demographic Yearbook, 1966* ... (1967), table 10. For an analysis of data available around 1950, see Valaoras, "Foetal, peri-natal and infant mortality" (1955).

<sup>102</sup> United Nations, *Demographic Yearbook, 1966* ... (1967), table 10.

<sup>92</sup> Hansluwka, "Some considerations about statistics of mortality" (1968), p. 146. See also Tietze, "Introduction to the statistics of abortion" (1953), pp. 136-137.

<sup>93</sup> The author estimated that another 10 per cent are terminated later in the pregnancy, so that only about 65 out of 100 pregnancies normally result in a live birth. See Valaoras, "Discussion" (1953), p. 143; Valaoras, "Foetal, peri-natal and infant mortality" (1955), p. 330. A slightly lower figure was found by Tietze and Martin. See their "Foetal deaths, spontaneous and induced ..." (1957), p. 175. A United Nations study cited the range of estimates of the loss during the entire pre-natal period as extending between 20 and 70 per cent. United Nations, *Foetal, Infant and Early Childhood Mortality*, vol. I ... (1954), p. 1.

<sup>94</sup> For a discussion of these problems, see United Nations, *Handbook of Vital Statistics Methods* (1955), pp. 46-60.

<sup>95</sup> According to international recommendations for infant mortality statistics, "early infancy" is defined as the first 28 days of life. In actual practice, however, some countries tabulate and report deaths in the first calendar, rather than lunar, month of life. See United Nations, *Principles for a Vital Statistics System* ... (1953), p. 21; ———, *Handbook of Vital Statistics Methods* (1955), p. 191; ———, *Demographic Yearbook, 1961* ... (1962), p. 32.

<sup>96</sup> Peller, *Quantitative Research in Human Biology and Medicine* (1967), p. 146.

ratio is higher among males than among females, the excess of the male ratio having a modal value of about 20 per cent, according to a study of twenty-six countries.<sup>103</sup>

53. Long-term trends in four European countries and Canada, all having reputedly good statistics, show stillbirth ratios generally fluctuating in the 20s from 1915 until after 1940, when a downward trend became more noticeable. Japan, on the other hand, showed a continuous and pronounced drop in its stillbirth ratio from its original high level during the same period.<sup>104</sup>

54. When stillbirths and deaths in the first week of life are combined, it is found that the resulting perinatal mortality constitutes by far the largest component of mortality up to the end of the first year of life in most countries of Central and Northern Europe. In fact, where infant mortality is now at a very low level, perinatal deaths exceed the total number of deaths from the first week up to thirty or thirty-five years of age.<sup>105</sup> The mean perinatal ratio in twenty developed countries, most of which had reliable statistics, was about 28 per 1,000 live births in 1960-1964. The range was from about 20 in Czechoslovakia to above 40 in Portugal. Substantial progress in controlling perinatal mortality is indicated by the fact that the ratio was reduced by more than one-fifth in the same twenty countries in a period of less than a decade. In 1952-1954 the average ratio was 35-36 per 1,000 live births.<sup>106</sup>

55. Examining ratios of perinatal mortality for England and Wales over a longer time period, Peller found that the ratio dropped from 61 per 1,000 live births in 1936-1939 to 32 in 1960-1962, or by nearly one-half. During the same period, however, the mortality rate for the second week to the end of the first year of life declined by three-fourths.<sup>107</sup> According to the available data for Austria, the perinatal mortality ratio declined from 62 in 1927 to 35 in 1960, representing a fall of 43 per cent. During the same period, neonatal mortality dropped by 52 per cent and post-neonatal mortality by 83 per cent.<sup>108</sup>

56. The contribution of pre-natal and post-natal care in reducing perinatal mortality is suggested by the fact that countries with low ratios are those with well-developed medical care programmes. In Portugal, which has one of the highest perinatal mortality rates reported in Europe, only about half of all confinements in 1959 were

attended by a physician or qualified midwife, whereas the corresponding proportion was over 90 per cent in countries with low perinatal mortality such as Czechoslovakia, Finland, Hungary, the Netherlands, Norway, Sweden and the United Kingdom.<sup>109</sup>

57. Various studies have examined the relationship between rates of stillbirths, perinatal or neonatal mortality on the one hand, and such factors as age of mother and birth order on the other. In general, the mortality ratios studied have been found to rise with the increasing age of the mother and with higher birth orders, although some exceptions have been noted.<sup>110</sup>

## 2. LEVELS AND TRENDS OF INFANT MORTALITY

58. Infant mortality rates<sup>111</sup> are much more widely available than any of the other measures of pre-natal and post-natal mortality discussed above. In fact, estimates of the infant mortality rate exist for nearly all countries for which the crude death rate is known. While the former are on the whole less reliable than the latter—since infant deaths are more likely to go unregistered than adult deaths—they have long been of interest to social scientists and persons concerned with public health problems. This is because the incidence of mortality during the first year of life has been considered one of the most sensitive indicators of the general level of living, being particularly responsive to changes in environmental and social conditions,<sup>112</sup> although, as discussed below, recent trends in developing countries seem to be diminishing its usefulness in this respect.

59. The range of infant mortality rates in the world's more developed regions in the mid-1960s was considerably wider than that of the crude death rates. On the one hand, the infant mortality rate had fallen below 20 per 1,000 live births in the Scandinavian countries, as well as in Australia, England and Wales, Japan, the Netherlands, New Zealand, and Switzerland. At the other extreme, an infant mortality rate of 87 was reported for Albania, 72 for Yugoslavia and 65 for Portugal in 1965. Argentina's rate was nearly 60, while rates in the 30s and 40s were common in Eastern and Southern Europe. In Northern

<sup>109</sup> World Health Organization, "Causes and prevention of perinatal mortality" (1967), p. 47.

<sup>103</sup> United Nations, *Foetal, Infant and Early Childhood Mortality*, vol. 1 ... (1954), p. 26. Some tendency has been observed for the sex ratio among stillbirths to decline. Sutherland, *Stillbirths: their Epidemiology and Social Significance* (1949).

<sup>104</sup> United Nations, *Foetal, Infant and Early Childhood Mortality*, vol. 1 ... (1954), pp. 25-26.

<sup>105</sup> World Health Organization, "Causes and prevention of perinatal mortality" (1967), p. 43.

<sup>106</sup> Data from United Nations, *Demographic Yearbook*, 1961 ... (1962), table 11, and ———, 1966 ... (1967), table 12.

<sup>107</sup> Peller, *Quantitative Research in Human Biology and Medicine* (1967), pp. 147-154. In a study of the ruling families of Europe, the author found that perinatal mortality fell from about 100 in the sixteenth and seventeenth centuries to 8 in 1900-1935, the latter figure not being matched in any population today so far as is known.

<sup>108</sup> Czermak and Hansluka, "Infant mortality in Austria" (1962), p. 199. For trends in some other countries, see Shapiro, Schlesinger and Nesbitt, *Infant, Perinatal, Maternal and Childhood Mortality* ... (1968), pp. 121-122.

<sup>110</sup> See, for example, Benjamin, *Social and Economic Factors Affecting Mortality* (1965), p. 46; Heady *et al.*, "The independent effects of social class ..." (1955), pp. 499-502; Tabah and Sutter, "Influence respective de l'âge maternel et du rang de naissance ..." (1948). Heady and Heasman, *Social and Biological Factors in Infant Mortality* (1959). The British perinatal mortality survey of 1958 showed that the risk of death rose with advancing age of mother after age thirty, that it was lowest for second births, and highest for fourth and subsequent births. Butler and Bonham, *Perinatal Mortality* ... (1963), pp. 20-23.

<sup>111</sup> The infant mortality rate is usually calculated as the number of deaths occurring to infants under one year of age in a given calendar year per 1,000 live births in the same year.

<sup>112</sup> See, for example, United Nations, *Preliminary Report on the World Social Situation* (1952), p. 13; ———, *Report on International Definition and Measurement* ... (1954), p. 28; ———, *International Definition and Measurement of Levels of Living* ... (1961), p. 5; Titmuss, *Birth, Poverty and Wealth* (1943), p. 11.

America and in the USSR infant mortality rates were in the 20s.<sup>113</sup>

60. In some parts of the world's developing regions infant mortality rates have already dropped to moderate or low levels. In fact, by the mid-1960s a few countries in these regions had levels of infant mortality below those found generally in Eastern and Southern Europe. Thus, rates in the 20s were found in China (Taiwan), Hong Kong and Singapore; in the 30s in Jamaica and in the 40s in Puerto Rico and Trinidad and Tobago. Ceylon and Western Malaysia had rates in the 50s. Three countries of the Middle American Mainland with complete registration data—Costa Rica, El Salvador and Mexico—had rates of 75, 71 and 61, respectively, and the island of Mauritius had a rate of 64.<sup>114</sup>

61. Rates of 70 and less are not representative of the developing regions, however. In the more populous countries of Asia, rates are known to be much higher, though the questionable reliability of available data makes precise measurement impossible. Estimated infant mortality rates for India and Pakistan are well above 100.<sup>115</sup> Even Chile, which lies in the more developed temperate zone of South America, had an infant mortality rate above 100 in 1965. Still higher rates of infant deaths prevail in most parts of Africa. Sample surveys carried out in various parts of tropical Africa in the late 1950s and early 1960s showed that rates in excess of 200 per 1,000 live births are common. Rates of this level or above were reported, for example, for Central African Republic, Dahomey, Guinea, Senegal, Mali, and Upper Volta.<sup>116</sup>

62. Infant mortality rates of 200 or more were the rule even in the presently industrialized countries about 150 years ago.<sup>117</sup> Little, if any, decline occurred in the British Isles, France and Belgium during the nineteenth century, although such a trend had begun in certain other countries, notably in Finland, the Netherlands, Switzer-

land, and Italy, and fairly low levels of infant mortality rates had been reached in Norway and Sweden.<sup>118</sup> In the 1870s the rate in European countries is reported to have varied from 100 in Norway to nearly 300 in southern Germany,<sup>119</sup> and was approximately 260 in the Czech regions of Czechoslovakia,<sup>120</sup> 200 in Italy,<sup>121</sup> 150 in the United Kingdom (England and Wales),<sup>122</sup> and 130 in Sweden.<sup>123</sup> By the beginning of the twentieth century it had fallen considerably in some countries, but remained high in others, varying in countries of Western Europe from less than 100 in Sweden to more than 200 in Austria.<sup>124</sup> In Russia about this time, the infant mortality rate was estimated to be above 250,<sup>125</sup> and rates above 200 are shown in the official statistics for those countries of Eastern Europe for which data are available. In the eastern part of the United States the infant mortality rate at the turn of the century was estimated at about 125.<sup>126</sup>

63. In most of the industrialized countries having a long series of vital statistics records, infant mortality rates declined by three-fourths or more during the half century preceding the early 1960s. Thus, in such countries as Austria, Denmark, Finland, Japan, Netherlands, Sweden, Switzerland and the United Kingdom (England and Wales), infant mortality rates in 1960-1964 were less than 20 per cent of what they had been in the first decade of the century (table V.10).

64. The rapid fall of infant mortality began somewhat later in Southern and Eastern Europe than in Northern and Western Europe and in Australia and New Zealand. Infant mortality rates of 100 and more were the rule in Southern and Eastern Europe in the late 1930s, and it has been the successful bringing down of this component of mortality that has been responsible for the reductions in crude death rates which have occurred in these regions since the Second World War.<sup>127</sup> Nevertheless, it has been observed that while infant mortality rates have been reduced by roughly one-half in Portugal and Yugoslavia as well as in Argentina, since 1900, the current level in these countries is still well above the average for developed

<sup>113</sup> As mentioned above, the comparability of infant mortality rates is affected by differing definitions of live births and foetal deaths. Examining the impact of such diversities, Shapiro and Moriyama concluded that part, but not all, of the excess of the infant mortality rate in the United States as compared with certain European countries could be attributed to differing definitions and practices. Shapiro and Moriyama, "International trends in infant mortality ..." (1963), pp. 747-760.

<sup>114</sup> Rates quoted in these paragraphs are from United Nations, *Demographic Yearbook*, 1967 ... (1968), table 12.

<sup>115</sup> For India, see Coale and Hoover, *Population Growth and Economic Development* ... (1958), p. 357; for Pakistan, see Robinson, "Recent mortality trends in Pakistan" (1967), p. 29; Stoeckel, "Infant mortality trends in rural East Pakistan" (1970).

<sup>116</sup> Coale, "Estimates of fertility ..." (1968), pp. 182-183. For countries of former French Africa and Madagascar combined, the infant mortality rate for 1960-1964 was estimated at about 250 for males and 220 for females. France, Institut national de la statistique et des études économiques, Service de Coopération, *Perspectives de population* ... (1963), p. 25. For other estimates of very high infant mortality for parts of tropical Africa, see Blanc and Théodore, "Les populations d'Afrique noire et de Madagascar ..." (1960), pp. 430-431; Smith and Blacker, *Population Characteristics* ... (1963), pp. 41-42.

<sup>117</sup> See, for example, Mayo-Smith, *Statistics and Sociology* (1895), pp. 144-145; Germany, Statistisches Amt, *Stand und Bewegung der Bevölkerung des Deutschen Reichs* ... regions.<sup>128</sup> A spectacular decline in infant mortality occurred in the USSR, where the rate dropped from an estimated 269 in 1913 to 182 in 1940 and 29 in 1964.<sup>129</sup>

65. Even in those countries where the reduction of mortality was most advanced and where little further decline of crude death rates was registered after the 1930s, improvements in infant mortality continued.<sup>130</sup> Recently, however, a slackening of the rate of decrease has been observed in several countries which had already reached very low levels of infant mortality.<sup>131</sup>

66. While trends in infant mortality cannot be traced with any degree of accuracy for most countries in the world's developing regions, there is evidence for a few countries with relatively good statistics of striking declines

<sup>128</sup> In Yugoslavia the infant mortality rate was reduced from about 150 per 1,000 live births in the 1920s to about 80 in the early 1960s. Playec, *Smrtnost stanovništva u Jugoslaviji* ... (1968), p. 6. See also Tasić et al., *Smrtnost odojčadi u Jugoslaviji* (1966), p. 29.

in recent decades. Table V.11 shows data for ten developing countries, all of which had infant mortality rates of more than 100 as late as 1935-1939. In the succeeding twenty-five years two of these countries—China (Taiwan) and Singapore—had achieved a cut in the infant mortality rate of 80 per cent, or comparable to that which occurred during the last half century in those industrialized countries which achieved the most rapid declines. In Taiwan the infant mortality rate fell from 144 in 1935-1939 to 28 in 1960-1964, and in Singapore the comparable decline was from 152 to 31. Declines of 60 per cent or more in the infant mortality rate were also recorded in Ceylon, Jamaica, Malaysia, Mauritius, Puerto Rico and Trinidad and Tobago during the same period. Significant, though less dramatic declines in infant mortality were registered in the United Arab Republic, where the rate dropped from about 163 in 1935-1939 to 109 in 1960.<sup>132</sup>

<sup>a</sup> Four-year average.

67. With the slackening of the downward trend in the more advanced countries, and continued rapid progress in other countries, greater uniformity in levels of infant mortality can be expected in the future. As pointed out above, some overlapping of rates has been observed between countries in the world's developed and developing regions. This situation has brought into question the continued utility of the level of infant mortality as an indicator of differences between countries in social and economic conditions, since it now appears that public health measures can be successfully applied to lower mortality without very great changes in the economic and social structure of the developing countries.<sup>133</sup> Thus, some of these countries have not made such great strides in respect to industrialization and social development as the levels of their infant mortality rates would ordinarily suggest.

<sup>132</sup> Sarhan, "Mortality trends in the United Arab Republic" (1967), pp. 359-360.

<sup>133</sup> United Nations, *1967 Report on the World Social Situation* (1969), p. 10.

### 3. CHARACTERISTICS OF INFANT MORTALITY

68. The levelling-off process that characterizes recent trends of infant mortality in low-mortality countries has been attributed to difficulties experienced in reducing endogenous mortality. Examining data for seven countries of low mortality, Bourgeois-Pichat found endogenous mortality to be three to seven times as high as exogenous mortality in Sweden, the Netherlands and the United States in 1963, and more than twice as high in Canada and England and Wales. He concluded that exogenous mortality would soon virtually disappear in low-mortality countries, and noted that Sweden, where exogenous mortality amounted to only 1.8 per 1,000 live births, had already almost reached that state.<sup>134</sup>

69. Variations in infant mortality levels among countries are least during the neonatal period, i.e. during the first month of life, and increase with age.<sup>135</sup> Hence, an inverse relation has been found between the general level of the infant mortality rate and the proportion of infant deaths which occur shortly after birth. An examination of infant mortality data for numerous countries for the period 1936-1945 showed that in countries where the infant mortality rate is below 50, between one-half and two-thirds of infant deaths took place in the first month of life. The corresponding proportion was only slightly more than one-third in countries where the infant mortality rate exceeded 100. The long-term trends of infant mortality in individual countries are consistent with this pattern, in that they show only a very modest decrease over time in mortality occurring during the first week of life, and a very substantial fall in infant mortality beyond this age. Thus, in Sweden between 1915-1917 and 1943-1945 the mortality rate for infants aged less than one week declined by only 4 per cent, while a decline of nearly three-fourths was registered at ages from one week to eleven months.<sup>136</sup>

70. The different trends which have been observed in neonatal and post-neonatal mortality are clearly of much significance for the probable future course of infant mortality in particular countries. In countries where

<sup>134</sup> Bourgeois-Pichat, "Evolution récente de la mortalité infantile" (1964), pp. 436-437. In contrast with the pattern in the countries studied by Bourgeois-Pichat, nearly equal rates of endogenous and exogenous mortality were found in the Czech regions of Czechoslovakia in 1957. Vysušilová, "O České kojenecké úmrtnosti" (1959), p. 95.

<sup>135</sup> For example, in 1963 neonatal mortality in Austria exceeded that in Switzerland and the Federal Republic of Germany by 38 and 8 per cent, respectively, but the post-neonatal rate in Austria was double that in Switzerland and exceeded the German rate by 38 per cent. Czermak and Hansluka, "Statistische Grundlagen der Pädiatrie 6 ..." (1967), p. 178.

<sup>136</sup> United Nations, *Foetal, Infant and Early Childhood Mortality*, vol. 1 ... (1954), pp. 34-35. In the Czech regions of Czechoslovakia between 1920 and 1950 the neonatal mortality rate attributable to exogenous causes declined by about three-fourths, while the post-neonatal infant mortality rate (exogenous) fell by about two-thirds, and the neonatal rate from endogenous causes was cut by over one-half. Vysušilová, "O České kojenecké úmrtnosti" (1959), p. 92. In England and Wales between 1911 and 1949, the total infant mortality rate declined by three-fourths, while the mortality rate in the first month of life declined by one-half. Taylor, "The changing pattern of mortality ..." (1954), p. 7. For analyses relating to Denmark and Yugoslavia, see, respectively, Matthiesen, *Infant Mortality in Denmark* ... (1965), p. 26, and Breznik and Šekarić, "Smrtnost stanovništva ..." (1963).

infant mortality has now reached a very low level, a further reduction will be difficult without revolutionary new medical discoveries, since congenital defects and diseases of early infancy, which are responsible for the major portion of infant deaths in these countries, are little subject to control through public health measures and improvements in social and environmental conditions.<sup>137</sup> In those areas where infant mortality is still high, improvements in sanitation, hygiene and health education can be expected to lower mortality throughout the period of infancy, whereas neonatal mortality should respond favourably to increasing hospitalization for deliveries, and improved ante-natal and obstetric care.<sup>138</sup>

### 4. FACTORS AFFECTING FOETAL AND INFANT MORTALITY

71. A number of factors particularly relevant to foetal mortality or to mortality in early infancy are discussed below; among these are birth weight, gestational age, age of mother, birth order and illegitimacy. Socio-economic and other factors associated with both general and infant mortality are discussed in the section on mortality differentials (section E).

72. The maturity of the infant at birth has been shown to be an important factor influencing infant mortality. The principal measure used in statistical studies to classify the newborn infant by developmental maturity has been weight at birth. Analyses of data for January-March 1950 for the United States revealed that deaths of infants with low birth weights accounted for two-thirds of all neonatal deaths. Chances of survival improved considerably with moderate increase in weight, with the optimum birth weight for survival being 3,501-4,000 grammes.<sup>139</sup> When gestational age was introduced into the analysis, "it was found that the heavier babies at each gestation age level fared better than the lighter ones".<sup>140</sup> This pattern is seen in table V.12. Studies in England and Wales, and Scotland revealed similar relationships.<sup>141</sup>

73. In the United States, low birth weight incidence has been shown to be related to a number of other variables, including urban or rural residence, size of locality, sex, plurality (i.e., single or multiple birth), birth order, age of mother, type of attendant at birth, and

<sup>137</sup> United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), p. 21; Moriyama, "Infant mortality in certain countries of low mortality" (1967), p. 357.

<sup>138</sup> See Chandrasekhar, "Infant mortality in Madras City" (1967), p. 103; McKeown, "Social and biological influences on foetal and infant deaths" (1967), pp. 52-55; Valaoras, "Foetal, peri-natal and infant mortality" (1955), p. 334. Among the factors which have been mentioned as being associated with high levels of neonatal mortality in India are too frequent pregnancies, lack of antenatal care, malnutrition among expectant mothers, and ignorant midwifery. Chandrasekhar, "Infant mortality in India, 1901-1951" (1955), p. 392.

\* Rates not computed, less than ten deaths.

outcome of previous pregnancies,<sup>142</sup> although variation with age of mother and birth order has been shown to be only moderate.<sup>143</sup> The relationship with outcome of previous pregnancy has also been shown in data for England and Wales.<sup>144</sup>

74. No parameters of pregnancy loss have been as completely or as frequently explored as parity and age of mother. In general, the ratios of stillbirths, perinatal and neonatal mortality have been found to rise with increasing age of mother and with higher birth orders, although some exceptions have been noted.<sup>145</sup> The British perinatal mortality survey of 1958 showed that the risk of pregnancy loss rose with advancing age of mother after age thirty, that it was lowest for second births, and highest for fourth and subsequent births.<sup>146</sup> United States data for 1950 showed relatively high neonatal mortality rates for first births and high order births and for births to mothers under twenty and over thirty years of age.<sup>147</sup>

75. One of the earliest analyses of differentials in the risks of foetal and infant deaths according to legitimacy showed that in France in 1901 the male stillbirth rate was 49 for legitimate births and 76 for illegitimate births; by 1943 these rates had fallen to 30 and 47 for the two groups, respectively. Similar differences and trends were observed for female births. The same study showed that, for each

age group of mothers, infant mortality rates for illegitimate births exceeded those for legitimate births by 50 to 150 per cent in 1901, and by 1943 the differentials were even greater.<sup>148</sup>

76. The same type of differentials according to legitimacy can be traced in the statistics of other countries. For example, in Scotland the infant mortality rate of illegitimate children still remained higher than that of the legitimately born in 1963. The proportion of total births which were illegitimate had declined, however, from about 10 per cent in 1863 to about 5 per cent in 1963.<sup>149</sup> In Norway, the risk of death within the first year of life for an illegitimate birth has always been much greater than that for a legitimate one. For example, in 1901-1905, infant mortality rates per 1,000 live births were about 150 for illegitimates and 75 for legitimates. By 1956-1960, these rates had decreased to about 37 and 19, respectively, the relation between the two remaining at about 2 to 1. Although the higher mortality for illegitimates was insignificant as a factor in the national level of infant mortality, a comparison of the two groups is still of considerable interest from the socio-medical point of view, as it may throw light on the importance of the mother's environmental conditions for the viability of her child.<sup>150</sup> Substantially higher mortality among illegitimate births also exists in Denmark where, from 1951 through 1962, the mortality of illegitimate infants was 58 per cent higher than that of legitimate ones.<sup>151</sup> In England and Wales, the substantial excess mortality to which illegitimate births were formerly subject has

<sup>151</sup> United States, National Center for Health Statistics, *Infant and Perinatal Mortality in Denmark* (1967), pp. 10-11; Vedel-Petersen, in *Laerebog i Danmarks statistik* (1944), pp. 57-58, attributed the differences in Denmark to a number of factors, including the fact that a much higher proportion of illegitimate than of legitimate births are first births, which have generally higher mortality rates than second and subsequent births.

been greatly reduced since the Second World War, and illegitimate infants are no longer at a mortality disadvantage after the first week of life.<sup>152</sup>

77. Hansluwka found that infant mortality in Austria was 40 per cent higher among illegitimate than among legitimate births in 1961, and this differential was somewhat greater than had been observed at the beginning of the century. Mortality rates of illegitimates as compared with legitimates were 46 per cent higher in the neonatal group and 28 per cent higher for the post-neonatal group in 1961.<sup>153</sup> A smaller differential was observed in Yugoslavia, where in 1960-1962 the mortality of illegitimate infants was 25 per cent higher than that of legitimate ones.<sup>154</sup>

#### D. Causes of death

78. According to a recent compilation by the United Nations, statistics on deaths classified by cause were available for slightly less than one-third of the world's population. The percentage of the population covered by such statistics was over 95 in Northern America and Europe, around 80 in Oceania, and nearly 50 in Latin America, but in Africa and Asia the percentage was very low.<sup>155</sup> The existing data on causes of death are subject to many defects, e.g., when total deaths are under-registered, when the percentage of deaths not medically certified is high, or when a large proportion of deaths is attributed to senility, ill-defined and unknown causes, or to a residual category consisting of "all other diseases".<sup>156</sup> Serious obstacles to international comparisons of cause-of-death data arise from differences between countries in terminology, method of certification, diagnostic techniques and in the interpretation of death certificates by coders.<sup>157</sup>

<sup>152</sup> United States, National Center for Health Statistics, *Infant and Perinatal Mortality in England and Wales* (1968), pp. 28, 65. See also Benjamin, *Social and Economic Factors Affecting Mortality* (1965), pp. 46-47.

<sup>153</sup> Hansluwka, "Social and economic factors in mortality in Austria" (1964), p. 332.

<sup>154</sup> Tasić *et al.*, *Smrtnost odojčadi u Jugoslaviji* (1966), pp. 179-180. Earlier studies, for example, in Austria, Czechoslovakia, and Jamaica, confirmed a higher mortality among illegitimate infants. See Hecke, "Die Unehelichen in Österreich" (1936), p. 341; Srb, "Zvýšení kojenecké . . ." (1949). Roberts, in "A note on mortality in Jamaica" (1950), p. 76, explained the higher mortality rate among illegitimate infants as being related to differences in socio-economic levels of the parents rather than in terms of marital status *per se*. See also DePorte, "Inter-racial variation in infant mortality" (1925), p. 484.

<sup>155</sup> United Nations, Economic and Social Council, *Availability, Sources and Quality . . .* (1968), pp. 4-5.

<sup>156</sup> In many developing countries at least one-quarter of total deaths in 1965-1966 were allocated to such ill-defined categories. In Thailand, for example, as much as 65 per cent of total deaths in 1965 fell into ill-defined and residual categories. Even certain European countries, such as Belgium, France, Greece, Poland and Yugoslavia, reported between 26 and 31 per cent of total deaths in these categories in 1965-1966. United Nations, *Demographic Yearbook, 1967 . . .* (1968), table 24.

<sup>157</sup> For more detailed discussion of the problems of compiling, evaluating and analysing cause-of-death statistics, see the following sources: United Nations, *Demographic Yearbook, 1951* (1951), pp. 18-26; ———, *1966 . . .* (1967), pp. 35-36; United Nations,

79. Despite the limitations of the data, the broad world trend in mortality by cause of death is reasonably clear. In the developed countries, where infectious and parasitic diseases have been brought under control and some of them virtually eradicated, the proportion of deaths attributable to such diseases has decreased dramatically with declining mortality, while deaths from the degenerative ailments, mainly cancer and diseases of the heart and circulatory system, account for an ever-increasing proportion of the total. In countries where mortality is still relatively high, the opposite pattern prevails—mortality from the infectious and parasitic diseases is still of major importance.<sup>158</sup> The older age structure of the population in developed countries contributes to these differences, in view of the increasing incidence of the degenerative diseases with age.

80. A World Health Organization analysis of the leading causes of death in 1962-1964 in selected countries of both developed and developing regions brings these differing patterns into relief. Among the selected developed countries, the ten leading causes of death were responsible, on average, for 79 per cent of all deaths in 1964. This was a somewhat higher percentage than a decade earlier, and is indicative of a trend towards increasing concentration among a few leading causes.<sup>159</sup> Among the developing regions, on the other hand, there was a greater diffusion, with the ten leading causes of death accounting, on average, for only 56 per cent of all deaths.<sup>160</sup>

81. Among the developed countries whose data were analysed in the World Health Organization study, the leading cause of death in 1964 was heart disease, which accounted for nearly one-third of total deaths. Malignant neoplasms were the second most frequent cause (19 per cent), followed by vascular lesions affecting the central nervous system (13 per cent). These degenerative diseases accounted for nearly two-thirds of all deaths, thus illustrating the tendency towards concentration mentioned above. Accidents were responsible for about 5 per cent of deaths, and influenza and pneumonia together for about 3 per cent.<sup>161</sup>

*Handbook of Vital Statistics Methods* (1955), pp. 123-127; World Health Organization, "The accuracy and comparability of death statistics" (1967); Abramson, "Causes of death—international comparisons" (1967).

<sup>158</sup> According to Arriaga's classification of "infectious-communicable" diseases, deaths attributable to this group of diseases around 1960 ranged from 6 to 13 per cent in eleven developed countries, and from 33 to 61 per cent in the same number of developing countries. Arriaga, "Rural-urban mortality in developing countries . . ." (1967), p. 99.

<sup>159</sup> World Health Organization, "Causes of death: the ten leading causes of death for selected countries in North America, Europe and Oceania . . ." (1967), p. 33.

<sup>160</sup> World Health Organization, "Causes of death: the ten leading causes of death for selected countries in Africa, South and Central America and Asia . . ." (1967), p. 118. The percentage would have been even lower were it not for the distorting effect of including in the figures data for Japan and Israel, both of which have mortality patterns typical of developed countries.

<sup>161</sup> World Health Organization, "Causes of death: the ten leading causes of death for selected countries in North America, Europe and Oceania . . ." (1967), pp. 33-35. While there was little variation from country to country in the rank order of the highest-ranking causes of death, patterns became less uniform with descending

TABLE V.13. PERCENTAGE DISTRIBUTION OF DEATHS BY CAUSE IN SELECTED MODEL POPULATIONS

Cause of death	Populations with a "young" age structure		Populations with an "old" age structure	
	Model A e <sub>0</sub> = 50	Model B e <sub>0</sub> = 70	Model C e <sub>0</sub> = 50	Model D e <sub>0</sub> = 70
All causes .....	100.0	100.0	100.0	100.0
Infectious, parasitic and respiratory diseases .....	34.1	10.8	27.4	6.5
Cancer .....	5.6	15.2	7.9	16.4
Diseases of the circulatory system ...	18.7	32.2	26.0	46.5
Violence .....	4.3	6.8	4.0	5.2

SOURCE: Adapted from United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), pp. 111-112. See also pages 106-110 for a description of methods used in constructing these and other models.

82. The leading cause of death in selected countries of the developing regions in 1964 was found to be gastroenteritis (comprising gastritis, duodenitis, enteritis and colitis), responsible, on the average, for about 10 per cent of total deaths. The next four leading causes were, in order, heart disease (about 8 per cent), influenza and pneumonia (about 7 per cent), malignant neoplasms (about 7 per cent) and accidents (about 5 per cent).<sup>182</sup>

83. The typical pattern of causes of death in populations of different mortality levels has been illustrated by means of a series of models in a United Nations study of world mortality trends. Four of these models are presented in table V.13. It is seen that in a standard population with a "young" age structure (models A and B), as expectation of life at birth rises from 50 to 70 years, the proportion of all deaths attributable to infectious, parasitic and respiratory diseases declines from 34 to 11 per cent, while the proportion of deaths from cancer rises from 6 to 15 per cent, and the proportion from diseases of the circulatory system rises from 19 to 32 per cent. The effect of age structure is seen by comparing these models with those based on a standard population with a much older age structure (models C and D). Thus, model D with life expectancy of 70 years, but a higher proportion of older persons than model B, shows only about 6 per cent of all deaths resulting from infectious, parasitic and respiratory diseases while diseases of the circulatory system account for nearly half of the total. The cause-of-death patterns depicted in models A and D may provide a rough indication of differences between the world's developing and developed regions, since the former have young age structures and an average life expectancy of about 50 years, while the latter have relatively old age structures and an average life expectancy of about 70 years.

order. In addition to the five causes mentioned above, the following most frequently ranked among the ten leading causes in the selected countries: diabetes mellitus, congenital malformations, birth injuries, post-natal asphyxia and atelectasis, suicide and self-inflicted injury, bronchitis, tuberculosis, cirrhosis of liver, and nephritis and nephrosis. *Ibid.*, pp. 35, 40-49.

<sup>182</sup> World Health Organization, "Causes of death: the ten leading causes of death for selected countries in Africa, South and Central America and Asia ..." (1967), pp. 118-119. Also appearing among the ten leading causes were vascular lesions affecting the central nervous system, infections of the newborn, tuberculosis, measles, and nephritis and nephrosis.

84. As mentioned above, emphatic shifts in the relative importance of certain categories of causes of death have accompanied substantial declines in mortality. These changes are illustrated in the figures for England and Wales and the United States during the first half of the present century. Around 1900, when expectation of life at birth in these countries was about 50 years, almost 30 per cent of all deaths were due to infectious (including respiratory) and parasitic diseases, while in the 1950s, when life expectancy had increased to some 70 years, the corresponding percentage was 7 for the United Kingdom (England and Wales) and 5 for the United States. This striking decrease in the relative contribution of the infectious and parasitic diseases in these countries is believed to have been roughly typical of mortality trends and patterns in other countries of European culture as their general mortality decreased. Even though sufficiently accurate cause-of-death statistics are lacking for developing countries which are now undergoing rapid mortality decline, there are grounds for believing that it is the infectious and parasitic diseases which are decreasing fastest as a cause of death.<sup>183</sup>

85. With the ageing of population in the developed countries, the ratio of cancer deaths to total deaths has increased, since the incidence of cancer rises rapidly with age. Even after standardizing the death rate to eliminate the effect of changes in age structure, however, cancer mortality seems to have increased in certain countries. In the United States, for example, the crude death rate from cancer rose nearly 2.5 times between 1900 and 1954; after adjustment for changes in age composition, the increase was 70 per cent. It is difficult to estimate what portion of this remaining rise is actually due to higher cancer mortality, as improvements in case-finding and diagnosis also contribute to the increase.<sup>184</sup> Tsukahara's analysis of trends in age-standardized death rates from cancer in twenty developed countries during the 1950s provides impressive evidence of widespread increases among males. As seen in table V.14, rates for males rose

SOURCE: Tsukahara, "Trends in age-adjusted ..." (1966), p. 386.

in all but two of the countries studied; while the rates for females declined in most countries, the percentage decreases were substantially less than those relating to other causes.<sup>165</sup>

86. There is fairly clear evidence that mortality from cancer of the trachea, bronchi and lungs has continued to increase in the past two decades and has emerged as a major health hazard in many countries of the world. Males have been affected to a far greater extent than females by respiratory cancers, but increasing incidence has become evident among females over thirty-five years of age in a number of countries.<sup>166</sup> Mortality from leukaemia and aleukaemia has also been on the rise in recent years and constitutes a sizable fraction of cancer deaths in persons under thirty-five years.<sup>167</sup> Significant differences have been found in the structure of cancer mortality by sites among different populations. Thus, cancer of the stomach constituted more than half of all male cancer deaths in Japan in the 1950s, compared with only 10 per cent in the United States (white population).

<sup>165</sup> Tsukahara, "Trends in age-adjusted ..." (1966). Since the study covered a period of less than a decade (1952-1953 to 1960-1961), the data are not as likely to be affected by changes in diagnostic and classificatory procedures as are longer time series.

<sup>166</sup> World Health Organization, "The world health situation ..." (1967), pp. 355-356; Krohn and Weber, "Some characteristics of mortality ..." (1967), p. 334; see also Spiegelman, "Recent trends and determinants of mortality ..." (1956), pp. 54-55; Radkovský and Pirková, "Nepřiznivý vývoj rakoviny plic u mužů" (1968).

<sup>167</sup> Krohn and Weber, "Some characteristics of mortality ..." (1967), p. 335.

On the other hand, respiratory cancer as a cause of death had a much higher incidence in the United States than in Japan.<sup>168</sup>

87. With few exceptions, developed countries have also experienced a rise in mortality from cardiovascular diseases among males beyond age forty-five, whereas among females there has been a slowing down of the decline with increasing age, and in some countries, an increase in the rate beyond age seventy-five.<sup>169</sup> The fact that treatment of cardiovascular diseases is usually not curative, but is limited to postponing deaths, has been cited as a possible explanation for the observation that over a period of time, a decline in mortality among younger persons is accompanied by an increase among older persons.<sup>170</sup>

88. In the developing regions, the pattern of mortality by cause of death is markedly different from that of the developed regions. According to an analysis of deaths by cause in selected countries of Latin America, the leading causes of death in the 1960s were those prevailing in the more advanced countries early in the twentieth century, and included gastro-enteritis, pneumonia, tuberculosis, bronchitis, influenza, dysentery, measles, whooping cough, tetanus and typhoid. While great gaps in death rates for young children still exist between Latin American countries and the more developed regions, some notable improvements have been recorded over a short period. In Venezuela, for example, the gastro-enteritis death rate of 818 per 100,000 in the age group one to four years in 1941-1945 fell to 344 in 1950. Malaria eradication programmes, whereby flies as well as mosquitos succumbed to insecticides, are said to have contributed greatly to this decline.<sup>171</sup>

89. A striking example of the response of a disease to specific measures aimed at eradicating it has been the case of the parasitic disease, malaria. Data on the epidemiological status of malaria show that out of the 1,635 million people living in the originally malarious areas of the world, by the end of 1966, three-fourths were in areas where malaria had been eradicated or where eradication programmes were in progress.<sup>172</sup> In Ceylon total deaths from malaria numbered over 12,500 in 1946, the first year of the extensive DDT spraying programme, and the malaria death rate was 184 per 100,000 population. Ten years later, in 1956, 144 persons died from malaria,

<sup>168</sup> Segi and Tsukahara, "Comparison of the age-adjusted ..." (1965), p. 301.

<sup>169</sup> United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), pp. 87-95. The decline in rheumatic heart disease and increasing control over infections which have residual effects on the heart have contributed to mortality decline at the younger ages. World Health Organization, "Cardiovascular diseases ..." (1967), p. 3; Spiegelman, "Mortality trends for causes of death ..." (1965), p. 120.

<sup>170</sup> United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), pp. 95-96. However, this explanation cannot account for the substantial increase in male mortality from cardiovascular diseases at ages 45-64, according to Brass, who suggests that smoking, overeating and stress may all play some role. Brass, "The changing patterns ..." (1966), p. 5.

<sup>171</sup> Gabaldon, "Leading causes of death in Latin America" (1965).

<sup>172</sup> World Health Organization, "Malaria eradication in 1966" (1967), pp. 373-374.

a rate of less than 2 per 100,000 population.<sup>173</sup> Among other countries having benefited from malaria eradication programmes are Guatemala, Guyana, Mauritius, Pakistan and Venezuela.<sup>174</sup>

90. Smallpox has been completely eliminated from Europe, North America, Oceania, and most parts of Latin America, but it is still endemic in Africa, South-East Asia and part of the Eastern Mediterranean. Over 80 per cent of the world's smallpox cases are recorded in Asia, mainly in India, Indonesia and Pakistan. The institution of mass vaccination campaigns in recent years under the auspices of the World Health Organization has not yet produced a noticeable downward trend in the incidence of the disease, although the total world area with endemic smallpox has been shrinking.<sup>175</sup>

91. Cholera again became a threat to the health of the world when its containment to India and Pakistan and a few neighbouring countries was suddenly reversed in 1961. Epidemic waves of the disease invaded large areas of Asia, affecting many countries which had long been free of it. The control of cholera is more problematic than that of the other infectious diseases because it requires the construction of modern sanitation facilities and the education of the public in proper personal hygiene—measures which are both costly and time-consuming.<sup>176</sup>

92. Tuberculosis has lost much of its importance as a cause of death in a number of developed countries where it was once a grave problem. In England and Wales, for example, tuberculosis was the leading cause of death early in the century, and was responsible for one out of nine deaths. By 1960-1964, only one death in 180 was due to this disease.<sup>177</sup> That there is still room for substantial improvement in tuberculosis mortality in certain developed countries, however, is evident from the widely divergent death rates for the disease. A tabulation of age-standardized male death rates from tuberculosis of the respiratory system for 1961-1963 for twenty-one selected countries gave a rate of 2.8 (per 100,000 males) for the Netherlands, 8.5 for the United Kingdom, 37.5 for Hungary, 43.6 for Japan and 53.1 for Portugal.<sup>178</sup>

<sup>173</sup> Meegama, "Malaria eradication and its effect on mortality levels" (1967), pp. 207-208. Rates are computed from mid-year population figures in United Nations, *Demographic Yearbook, 1961* ... (1961), table 4. The relationship of malaria control to general mortality decline in Ceylon is discussed in section H.

<sup>174</sup> See Pampana, "Effect of malaria control on birth and death rates" (1955); Meegama, "Malaria eradication and its effect on mortality levels" (1967), pp. 230-237; Robinson, "Recent mortality trends in Pakistan" (1967), p. 34.

<sup>177</sup> World Health Organization, "The world health situation ..." (1967), pp. 352-353.

<sup>178</sup> World Health Organization, "Standardized death rates ..." (1966). On the remarkable decrease in mortality from tuberculosis in the younger age groups in Japan, see Mizushima, "Nihonjin shiboritsu ..." (1959).

In certain of the developing countries the death rates from tuberculosis, though decreasing, are still high. The disease has been estimated to cause from two to three million deaths annually at present, more than four-fifths of which are in the developing countries. With the preventive and curative tools now available, it is possible to carry out effective programmes against the disease, even under adverse socio-economic conditions.<sup>179</sup>

93. Although maternal mortality (i.e., deaths arising from deliveries and complications of pregnancy, childbirth, and the puerperium) has fallen to low levels in most of the developed countries, it is still a major cause of death among women of childbearing ages in many parts of the world, resulting in some countries in a higher female than male death rate at these ages. Maternal mortality levels have generally been declining, in developing as well as developed countries. For example, in 1950-1952 the number of maternal deaths per 100,000 live births was 571 in Ceylon and 72 in Denmark,<sup>180</sup> while the corresponding figures for a more recent year were 245 for Ceylon (1963) and 14 for Denmark (1965). There are considerable differences in reported maternal mortality levels even among the developed countries. For example, in 1965 the number of maternal deaths per 100,000 live births was 71 in the Federal Republic of Germany, whereas in the neighbouring countries it was as follows: Belgium, 23; Denmark, 14; France, 32; Netherlands, 29, and Switzerland, 38.<sup>181</sup> Among the factors contributing to the decrease of maternal mortality in the developing countries are increases in the proportion of women receiving pre-natal medical care and in the proportion of deliveries taking place in hospitals or maternity centres.<sup>182</sup>

94. Deaths from accidents rank fourth among the causes of death in most developed countries. In fact, they occupy first place in the cause-of-death list in the age-group from one to thirty-five years, reflecting the greatly diminished importance of fatal disease at these ages. Due to increasing automobile ownership, mortality from motor vehicle accidents has been rising, and in general constitutes over 40 per cent of all deaths attributable to accidents. Home accidents—caused by falls, burns, scalds and poisoning—are the number one cause of death during childhood after the first year of life.<sup>183</sup>

<sup>179</sup> World Health Organization, "The world health situation ..." (1967), p. 353.

<sup>180</sup> World Health Organization, "Maternal mortality, 1950-1960" (1964).

<sup>181</sup> Compiled from United Nations, *Demographic Yearbook, 1966* ... (1967), tables 7 and 20; and ——— 1967, ... (1968), tables 7 and 24.

<sup>182</sup> These proportions are still quite low in the developing countries, however, as indicated by the crude estimates presented in a recent review of world-wide conditions of maternity care. Among countries replying to a questionnaire, those in Asia reported, on average, that only about one-fifth of all deliveries took place in hospitals or maternity centres, while the corresponding proportion for Africa was about one-third. See Joint Study Group of the International Federation of Gynaecology and Obstetrics and the International Confederation of Midwives, *Maternity Care in the World* ... (1966), pp. 7-9.

(Continued on next page)

95. Deaths from suicide number an estimated half million persons a year<sup>184</sup> and are one of the leading causes of death among certain age groups in developed countries. A World Health Organization study in selected countries of North America, Europe and Oceania for the years 1956-1966 showed that suicide ranked third, fourth or fifth as a cause of death among persons aged 15-44 years. Suicide death rates increase progressively with age; in 1965 the rate was 6.4 per 100,000 population for persons 15-24 years old, and four times as high for persons aged 65-74 years. The total rate for males was over twice that for females. Several countries showed marked upward or downward trends in the death rate from this cause. Among the former was Hungary whose rate increased steadily from 20.6 to 29.8 per 100,000 population between 1955 and 1965, while the Japanese rate decreased from 25.2 to 14.7 during the same period.<sup>185</sup>

### E. Mortality differentials

96. Within the boundaries of individual countries important differences can be observed in the death rates for different subgroups of the population which share certain common characteristics. Among the characteristics identified as being related to mortality differences are geographic residence, socio-economic factors such as occupation, income level and educational attainment, ethnic group membership and marital status. Some of these differences are maintained over a period of time, despite reductions in general death rates, while others tend to diminish or disappear. Because of the interrelations among the various factors, interpretation of observed differentials is often difficult. For example, regional or ethnic differences in mortality may in some instances be the product of socio-economic differences, such as income and occupation.

#### 1. URBAN-RURAL DIFFERENTIALS

97. From the limited quantity of information available, it appears that mortality differences between urban and rural areas in most industrialized countries are now rather small, though they were not so formerly. Life tables representing recent mortality conditions showed less than one-half year's difference in average life expectancy at birth between urban and rural residents in such countries as Finland (1961-1965), Poland (1965-1966) and Sweden (1951-1960), and between residents of metropolitan areas and other inhabitants of the United States

(1959-1961).<sup>186</sup> Fairly uniform conditions of mortality seem also to have characterized urban and rural areas of the Soviet Union around 1958-1959, when average life expectancy at birth was reported to be 68.1 years in urban areas and 68.9 in rural areas.<sup>187</sup> In Denmark (1965) and in England and Wales (1960), mortality conditions appear to have been somewhat more favourable for rural residents.<sup>188</sup> A study of age-adjusted mortality rates by regions in Czechoslovakia for 1960-1961 showed that higher mortality levels were more prevalent in industrial districts having higher population density, whereas lower mortality rates were more frequent in agricultural districts with a lower percentage of urban population.<sup>189</sup> On the other hand, in Romania, life table data for 1963 suggest that urban inhabitants could expect to live almost two years longer than their rural counterparts.<sup>190</sup>

98. Data for most of the countries mentioned above show that the excess of male over female mortality is greater in urban than in rural areas. The particular pattern and possible causes of this phenomenon appear to vary in the few countries in which they have been investigated. In the Soviet Union, for example, the gap in excess male mortality between urban and rural areas has been found to be widest for young adults, a fact which Pressat attributed to the likelihood of a greater number of male accidental deaths in urban industries.<sup>191</sup> In England and Wales, on the other hand, the greater mortality disadvantage of males over females in urban, as compared with rural areas, manifests itself at ages above forty-five

<sup>186</sup> The values of life expectancy for urban and rural areas, respectively, were: for Finland, 68.8 and 69.1; for Poland, 70.1 and 69.7; for Sweden, 72.4 and 72.5; for the United States, 69.8 and 70.0. The data were derived from the following sources: Strömmer, *Väestöllinen muuntuminen Suomessa* . . . (1969), p. 147; Poland, Główny Urząd Statystyczny Polskiej Rzeczypospolitej Ludowej, *Polskie tablice wymieralności, 1965-1966* (1968), pp. 15-32; Sweden, Statistiska Centralbyrån, *Livslängdstabeller för årtiondet, 1951-1960* (1964), p. 24; United States, National Center for Health Statistics, *Life Tables for Metropolitan* . . . (1967).

<sup>187</sup> USSR, Tsentralnoe Statisticheskoe Upravlenie pri Sovete Ministrov SSSR, *Itogi vsesoyuznoi perepisi naseleniia* . . . (1962), pp. 254-279. Pressat, "Les premières tables de mortalité de l'Union soviétique . . ." (1963), p. 69.

<sup>188</sup> For Denmark, standardized death rates based on the age structure of the total population were 10.5 per 1,000 population in urban areas and 9.6 in rural. Computed from United Nations, *Demographic Yearbook, 1967* . . . (1968), pp. 184-185, 421. Age-standardized death rates for England and Wales in 1960 were 12.4 in conurbations and urban areas with population of 100,000 and over, 12.1 in other urban areas and 11.0 in rural districts. years.<sup>192</sup> In Austria, recent data show that the largest difference between urban and rural areas in male excess mortality occurred among persons under forty-five years of age, but in this case it was rural residence that proved to be highly disadvantageous to males, owing to a high accident death rate.<sup>193</sup>

99. Prior to the twentieth century, mortality was generally higher in urban than in rural areas of countries of Europe and Northern America, and differences were often substantial. In the United States in 1830, mortality conditions were far worse in the large cities than in the small cities or the rural areas, according to a life table for that time constructed by Jaffe and Lourie.<sup>184</sup> While an average life expectancy of about 40 years was calculated

100. Long-term mortality trends in most of these countries have been characterized by a progressive narrowing of the urban-rural differential. As shown in table V.15 above, more rapid mortality decline in urban than in rural areas had eliminated the once substantial differential in Sweden by the 1930s. In Norway, a near equality of urban and rural mortality rates was reached around 1950 for females, though for males the rural districts retained an advantage. Urban mortality appears to have exceeded that in rural areas in Japan in 1920, but a decade and a half later rates in the two areas were equal.

101. The pattern of urban-rural mortality differentials may have differed in parts of Eastern and Southern Europe which industrialized later than did the Western and Northern regions. For Poland, the earliest data available pertain to 1931-1932 and show a decided urban advantage in life expectation. But with the more rapid decline in mortality in the rural areas, the gap narrowed and differences between urban and rural life expectancies had been virtually eliminated by 1960-1961 (table V.15).

102. Within a given country, rural-urban residence has usually been related to infant mortality in much the same way as to general mortality. Prior to the twentieth century the infant mortality rate, like the total death rate, was higher in cities than in rural areas.<sup>199</sup> In Sweden, for example, the infant mortality rate in the middle of the eighteenth century was about 400 per 1,000 live births in Stockholm, while the average rate for Sweden was about 200.<sup>200</sup> In both Norway and Sweden, where statistics on urban and rural infant mortality go back a long way, infant mortality rates were approximately 50 per cent higher in urban than in rural areas throughout the second half of the nineteenth century (see table V.16). Thereafter, the gap began to close, and in the 1920s in Sweden and in the late 1930s in Norway, urban and rural rates were nearly equal; in succeeding periods rates have been slightly lower in the towns in both countries. In the Netherlands, while infant mortality was higher in the cities at the beginning of the industrial revolution, by the end of the nineteenth century the urban areas had gained an advantage owing to the development of better hygienic measures. Before the Second World War infant mortality rates showed an inverse correlation with size of municipality, but as infant loss came under greater control after the war, differences by size of municipality largely disappeared.<sup>201</sup>

103. In Bulgaria, infant mortality levels appear to have been uniformly high in urban and rural areas in the early 1920s when the country was little industrialized, but a widening gap between urban and rural rates developed

in succeeding years as urban rates began to fall, while rural rates for a time showed little improvement. After the Second World War, infant mortality fell rapidly in both rural and urban areas, and in the mid-1960s rural rates were still substantially higher than the urban (table V.16). Data for the Soviet Union for 1958-1959 show that the fairly similar general mortality rates in urban and rural areas masked a considerable excess of mortality among rural children, which may reflect less satisfactory health education and facilities for prevention and treatment of disease in the rural areas.<sup>202</sup>

<sup>202</sup> Infant mortality did not show a rural excess, but was about the same in urban and rural areas. There was some suggestion of a possible underregistration of infant deaths in rural areas, however. Pressat, "Les premières tables de mortalité de l'Union soviétique ..." (1963), pp. 81-85.

<sup>199</sup> See, for example, Bailey, *Modern Social Conditions* (1906), p. 321; and Newman, *Infant Mortality: a Social Problem* (1906), pp. 38-42.

<sup>200</sup> Price, *Observations on Reversionary* ... (1812), pp. 233, 235.

<sup>201</sup> United States, National Center for Health Statistics, *Infant Loss in the Netherlands* (1968), p. 9. Recent figures for Denmark show a very slight differential in favour of rural areas. United States, National Center for Health Statistics, *Infant and Perinatal Mortality in Denmark* (1967), pp. 17, 56. For an analysis of differentials in infant mortality rates in different zones within selected towns in Czechoslovakia, see Musil and Balík, "Územní rozložení kojenecké úmrtnosti ..." (1961).

104. In the developing countries, the greater concentration of medical facilities and public health services in cities, as well as certain characteristics of the urban population—better education, higher incomes, an awareness of health problems—might be expected to result in lower urban than rural mortality. On the other hand, problems of sewage disposal, contamination of drinking water and poor housing conditions may be more critical to health in urban areas owing to the high density of population.<sup>203</sup> Because the available data on mortality conditions in the urban and rural sectors of developing countries are meagre and their quality poor, it is difficult to establish the size and direction of the urban-rural mortality differential with certainty. In any comparison of rural and urban mortality rates in developing countries, there is a strong possibility of a greater deficiency in rural than in urban death registration. This, together with the better health conditions in urban areas mentioned above, has led many authors to hypothesize an urban mortality advantage, even when the statistics show no clearcut trend, or even show a lower rural mortality.

105. A case in point is Arriaga's analysis of mortality data for Mexico. While the official data showed similar urban and rural mortality levels, Arriaga's analysis of these data by states led him to doubt the completeness of the statistics for rural areas. He constructed for each state an index of accessibility of the registry offices, and found that in states where this index was lower than average, the rural death rates were also lower than average, and lower than the urban rate, supporting his hypothesis that registered rural mortality is incomplete.<sup>204</sup> The view has frequently been expressed that urban mortality is lower than rural in other parts of Latin America as well.<sup>205</sup>

106. Data for Africa appear to confirm a similar pattern of lower urban than rural mortality. Despite poor urban living conditions, infant and early childhood mortality is almost everywhere lower in and around the towns of tropical Africa than in the rural areas. Certain rural surveys suggest that one out of three African children dies before age five, while in the towns the figure is thought to be about one out of four.<sup>206</sup>

107. Using data from a sample survey conducted in the Democratic Republic of the Congo in the mid-1950s, Romaniuk estimated an expectation of life at birth of only about 35 years in the rural areas, compared with

about 50 years in the urban areas.<sup>207</sup> The results of a series of sample surveys conducted in some countries of Francophone Africa in the early 1960s showed urban mortality to be consistently lower than rural mortality. Although the differential was slight in some countries (e.g., Central African Republic and Chad), in others it was substantial (e.g., Dahomey, Gabon and West Cameroon). The more favourable mortality conditions in the urban areas have been attributed to the concentration there of the highest income groups, the highest school attendance ratios, superior public health services and hospital and medical facilities, and to differences in the way of life. The poor hygienic conditions often found in urban areas, however, serve to retard the improvements in mortality which the afore-mentioned advantages of urban living would be expected to bring about.<sup>208</sup>

108. For recent years death rates for health bureau localities in rural areas of the United Arab Republic surpassed those in urban areas, even without adjustments for the under-registration which is certain to exist. This is not surprising in view of the substantial differences in medical personnel and hospital facilities between the two types of areas.<sup>209</sup> In Turkey, according to a demographic survey, mortality rates in rural areas were higher than those in urban areas at nearly all ages, the estimated crude death rate being 17 per 1,000 in the former and 11 in the latter.<sup>210</sup> Taking into account the limitations of available data for India, Sovani concluded that urban death rates are lower than rural death rates. In his view, certain unfavourable aspects of the urban environment are more than compensated for by the availability of greater medical facilities and the increased disposition on the part of urban dwellers to take advantage of them.<sup>211</sup> Results of the National Sample Survey, eighteenth round, taken in India in 1963-1964, showed an infant mortality rate of about 124 for males and 110 for females in rural areas, as compared with 88 and 82, respectively, in urban areas. For both sexes, the urban-rural differential was greater in the neonatal than in the post-neonatal period.<sup>212</sup>

<sup>206</sup> Smith and Blacker, *Population characteristics* ... (1963), p. 42. On the reasons for lower mortality in tropical African towns see Caldwell, "Introduction" (1968), p. 11.

Data from the Mysore Population Study point to lower mortality in Bangalore City than in the rural areas of Mysore State, but it is not clear from the survey results whether the towns have higher or lower mortality than the rural areas.<sup>213</sup> In Madras City, infant mortality rates have been found to be considerably lower than those in the adjacent rural areas, because of the superior health and medical services that the city residents enjoy.<sup>214</sup>

109. A strong association has been shown to exist between infant mortality rates and the proportion of rural population in each of the eleven states of the former Malaya. The two states having the lowest infant mortality rates in 1961-1963 were the most highly urbanized states, while the four states with the highest infant mortality rates were among the states with the greatest percentage of rural population. These states also had the lowest literacy rates and an acute shortage of medical personnel.<sup>215</sup>

110. In Taiwan, a country with reliable vital statistics, 1961 data showed death rates to be inversely correlated with the size of localities, being lowest in the principal cities and highest in the rural areas.<sup>216</sup> From the results of a demographic survey in Indonesia, Ueda estimated that infant mortality was higher in the rural areas of Java-Madura in 1963 than in the large cities and other urban places.<sup>217</sup>

## 2. GEOGRAPHICAL DIFFERENTIALS

111. Geographical differences in mortality are found in countries of both high and low death rates, and seem to be the result, in large measure, of geographical differences in social and economic conditions. In general the magnitude of geographical differentials tends to decrease with the fall in death rates. In Czechoslovakia, for example, as general mortality fell between 1929-1932 and 1960, the gap in life expectancy between Czech and Slovak regions decreased from about six years to less than one year. This contraction was due to a more pronounced mortality decline among the Slovaks.<sup>218</sup>

112. Of the six major regions in Yugoslavia, Slovenia had the highest expectation of life for both males and females (65.6 years and 70.7 years, respectively) in 1958-1959. The lowest life expectancy for males was found in Bosnia and Herzegovina (58.4 years) and for females in Macedonia (60.6 years).<sup>219</sup> In 1962 infant mortality

rates ranged from a low of 30 per 1,000 live births in Slovenia to a high of 138 in Macedonia.<sup>220</sup>

113. In France in recent years the north has had higher infant mortality rates than the country as a whole, even if allowance is made for geographical differences in the socio-occupational structure of the population, and despite the fact that the north is far from being an economically backward region.<sup>221</sup> A sample survey in this region found the excess infant mortality to be due to social and cultural factors and to poorer knowledge of sanitary hygiene.<sup>222</sup> In Italy, geographical differences in socio-economic structure also help to explain variations in the prevalence of specific diseases as, for example, the higher cardiovascular mortality rates in northern, industrial Italy than in the south.<sup>223</sup>

114. In the United States in 1950 there was still a 40 per cent difference between the highest and lowest mortality rates among the states, after making adjustments for differences in age structure.<sup>224</sup> However, geographical differences become quite small if separate calculations are made for the white and non-white populations.<sup>225</sup> In Australia, Canada and New Zealand, as well as in the United States, geographical variations in crude death rates and infant mortality rates have been decreasing in magnitude in recent decades.<sup>226</sup>

115. Considerable geographical differentials in mortality rates are also reported for countries of high mortality, though in many cases the accuracy of the estimates is very uncertain. In Tanganyika, the more developed Northern Province was estimated to have a crude death rate of 19 and an infant mortality rate of about 150 in 1957, whereas the comparable rates for the Western Province were 27 and 200, respectively.<sup>227</sup> Sharp geographical variations also appear in 1962 estimates for Kenya, where the infant mortality rate in the region of highest mortality was more than double that in the region having the lowest mortality rates.<sup>228</sup>

116. Estimates calculated from Indian census data show a crude death rate of about 23 for the country as a whole in 1951-1960, with the lowest rate (16) estimated for Kerala State, and the highest (27) for Assam. The state variations were said to reflect differences in the pace of the spread of preventive and curative health

services.<sup>229</sup> In the nine provinces of Ceylon, crude death rates ranged from 6.6 to 10.9 in 1960.<sup>230</sup>

117. Estimates of life expectancy for the different states of Brazil, calculated from census age data, suggest a wide geographical variation, though full confidence cannot be placed in their reliability. For the period 1940-1950 highest life expectancy—53 years—was found in Rio Grande do Sul, and lowest life expectancy—36 years—in Mato Grosso. Mortality conditions also appeared to be relatively unfavourable in the Amazon Basin, and relatively favourable in the more developed States of São Paulo, Santa Catarina and the Federal District.<sup>231</sup>

### 3. OCCUPATIONAL AND OTHER DIFFERENTIALS

118. Although mortality recently has fallen to moderate levels in many countries that have achieved only modest advances in economic development, it is generally true that rich countries have lower death rates than poor countries. Within countries, it is the groups which have achieved the highest socio-economic status, as measured by such indicators as income, occupation, education and the like, who are found to have lower than average mortality. As pointed out earlier, these various factors affecting mortality are interdependent—occupation is related to education; income is related to occupation, and both income and education may influence diet, housing conditions and living habits. Since it is not feasible to attempt to assess the influence on mortality of these factors individually, writers have often taken one factor as an index of all others. The factor most frequently studied is occupation, or social class based on occupation, although the measurement of occupational mortality presents many problems.<sup>232</sup>

119. One of the earliest analyses, that for Copenhagen and other Danish towns for the period 1865-1874, identified three broad social classes based on occupation of the head of household. The age-adjusted average annual death rate for males twenty years of age and over in Copenhagen was found to be nearly twice as high for the "poor" class (made up of workmen, servants and persons in almshouses) as for the "high" class (made up of capitalists, professionals, wholesale dealers and higher officers). The rates were 31.2 and 16.5 per 1,000, respectively. Smaller inverse correlations between mortality rates and social class were observed for males in other towns and for females. Particularly in Copenhagen, differences between the "middle" and "high" classes were

found to be considerably smaller than those between the "middle" and "low" groups.<sup>233</sup> Large class differences in mortality still persisted in Copenhagen in the early part of the twentieth century, when death rates among manual workers were found to be about twice as high as those for "white-collar" workers.<sup>234</sup>

120. In a study of deaths among male workers in France in 1907-1908, Huber found that mortality among employers was very much lower than among wage and salaried workers. Wage workers generally had higher mortality than salaried workers, with great variations occurring among the different occupations according to the particular risks involved. Thus, death rates for plumbers were double those for textile workers in most age groups.<sup>235</sup>

121. Systematic studies of occupational and social class mortality differentials have a long history in England and Wales, where data on occupational mortality go back to 1851. Analyses of data for five social classes showed that in 1921-1923 and 1930-1932, mortality rates for males aged twenty to sixty-four years rose progressively from social class I (professional) to social class V (unskilled). By 1950, however, these relationships had altered, and males in social class II (intermediate occupations) and social class IV (partly skilled occupations) were found to have the lowest and next lowest rates, respectively. Class V, however, still had substantially higher mortality than the other classes.<sup>236</sup> The fact that the pattern of mortality rates for married women, grouped according to occupational class of the husband, was similar to that for males, suggests that the influence of the different social and economic situations of the various occupational groups exceeded the influence of occupational hazards.<sup>237</sup>

122. In the United States, the relationship of mortality level to occupational status underwent a notable change during the first half of the twentieth century, with a marked narrowing of the differential between industrial workers and the remainder of the population. In 1911-1912 white male industrial workers aged twenty years could look forward to a life expectancy of only 36.9 additional years, six years less than the corresponding figure for all white males. By 1949, the expectation for industrial workers aged twenty had increased to 48.4 years, and was

<sup>229</sup> Jain, "State growth rates and their components" (1967), pp. 25-26. See also Raman, "A study of some aspects of mortality ..." (1968).

<sup>230</sup> Abhayaratne and Jayewardene, *Fertility Trends in Ceylon* (1967), pp. 70-73.

<sup>231</sup> Smith, *Brazil* ... (1963), pp. 108-109. See also Mortaras' estimates for 1940-1950 in Elizaga, *Métodos demográficos para el estudio* ... (1969), pp. 84-85.

<sup>232</sup> The limitations of data on mortality by occupation have been reviewed in a number of sources. See, for example, Daric, "Mortalité, profession et situation sociale" (1949); United Nations, *Handbook of Vital Statistics Methods* (1955), pp. 130-134; ———, *Demographic Yearbook, 1967* ... (1968), pp. 40-41; United States Public Health Service, *Mortality by Occupation and Industry* ... (1962).

<sup>233</sup> Cited in Collins, *Economic Status and Health* ... (1927), pp. 34-38.

<sup>234</sup> Jensen and Koefoed, *Befolkningsforholdene i det nittende Aarhundrede* (1919), p. 80.

<sup>235</sup> Huber, "Mortalité suivant la profession, d'après les décès ..." (1912). See also Daric, "Mortalité, profession et situation sociale" (1949), pp. 678-679.

<sup>236</sup> Logan, "Social class variations ..." (1955), p. 204. See also Wilson, "On mortality trends by occupation and social class" (1966). The narrower range of class differences in mortality in England and Wales as compared with the United States was considered to be possibly related to the more homogeneous population, more uniform climate and earlier introduction of medical insurance in the former country. Guralnick, "Socioeconomic differences in mortality ..." (1964), p. 296.

<sup>237</sup> Stocks, "The effect of ..." (1938), pp. 669-709.

only one year less than that of all white males of the same age.<sup>238</sup>

123. Occupational class variations were still present in 1950, however, as shown in various studies conducted by Guralnick and others. Among males 20-64 years of age, the death rate was 6.4 per 1,000 for the professional group, 7.6 for the intermediate group, and 10.6 for white labourers. The class differential was substantial at all ages studied with the exception of the group 55-64 years.<sup>239</sup>

124. Deviations from the usual inverse relationship between mortality levels and measures of socio-economic status have been observed recently in Hungary. Data for 1959-1960 show that the lowest age-standardized mortality rates occurred among the population classified as agricultural-manual (9.5 deaths per 1,000 population), and the highest among the non-agricultural manual group (11.2). The death rate for the non-agricultural non-manual population was intermediate. Thirty years earlier, in 1930-1931, the agricultural-manual group had had the highest age-standardized death rate (17.4) and the non-manual group the lowest (11.3). The reversal of the traditional order is said to have resulted partly from the significant improvement of living conditions of the agricultural population, and partly from increased social mobility.<sup>240</sup>

125. An analysis of mortality differentials in Austria by broad socio-economic categories showed that in 1951-1953 mortality rates were higher for males in working class occupations than for those in middle and upper class occupations at all ages above eighteen years. Males engaged in agricultural occupations, on the whole, also had more favourable mortality than did those in non-agricultural working class occupations.<sup>241</sup> In Amsterdam, where mortality had fallen to a low level, age-standardized death rates for six occupational groups for 1947-1952 showed very little variation, and the risk of death among the working class males aged 15-64 years appeared to be scarcely significantly higher than that for males in the liberal professions and civil service. These findings were attributed in part to the system of social legislation

affecting workers and the favourable standard of medical care.<sup>242</sup>

126. Summarizing the results of studies conducted in various countries, Antonovsky concluded that there was ample evidence of social class influence on mortality, but that such differentials may decline when mortality falls to a low level. He observed that whereas earlier studies had frequently shown a two to one ratio between mortality rates for the lowest and highest social class groups, the difference had narrowed to 1.4 to 1 or 1.3 to 1 by the 1940s. Moreover, not only have over-all class differentials narrowed, but differences among all but the lowest social class have been nearly eliminated. So far as age is concerned, the greatest class differences are found in young and middle adulthood—at about ages 30-44 years.<sup>243</sup>

127. An inverse correlation has also been found between social class and infant mortality, which has been shown to be particularly sensitive to social and environmental conditions. One early study found that in Dublin, 1883-1885, the children of professional and independent groups had a low rate of mortality, whereas those of the general service group, whose income was small, had a higher rate.<sup>244</sup>

128. Statistics for England and Wales since 1911 have shown an inverse relationship between parental social class, as determined by the father's occupation, and foetal and infant mortality.<sup>245</sup> An outstanding feature of this relationship is that, although foetal and infant mortality have been greatly reduced, there has been no narrowing of the differentials by social class. The range of the rates between the highest and lowest social classes has been much smaller for neonatal than for post-neonatal mortality. In 1949-1950, the neonatal mortality rates in class I (professional and managerial) and class V (unskilled workers) were, respectively, 13.5 and 21.9, while the post-neonatal rates were 4.9 and 17.9.<sup>246</sup> Other studies as well have shown that class differences in infant mortality are greater after the first month of life than in the early weeks following birth, when biological factors are of greatest importance.<sup>247</sup> Very limited data for the United States (upstate New York in 1950-1952 and California

<sup>238</sup> The Metropolitan Life Insurance Company, "Longevity of industrial workers" (1950), pp. 4-7. Whitney found that, as late as 1930, mortality rates of unskilled workers were nearly twice as high as those of professional workers. Whitney, *Death Rates by Occupation* ... (1934), p. 17.

<sup>247</sup> This was the finding, for example, in the following studies, which refer respectively to France, Hungary, Austria and Italy: Croze, "La mortalité infantile en France ..." (1963), p. 267; Szabady, "A csecsemőhalandóságot ..." (1961), p. 444; Hansluwka, "Die Säuglingssterblichkeit in Österreich ..." (1966); Chiassino, "Mortalità infantile e 'stratificazione sociale'" (1965).

in 1959) reaffirm an inverse relationship between mortality and level of father's occupation group.<sup>248</sup>

129. In addition to the many studies which have been concerned with mortality differentials by social class as defined according to broad occupational groupings, a number of other studies have examined mortality differences among income groups. In some early studies it was noted only that mortality was higher in the poorer districts of cities than elsewhere. This is said to have been true in Glasgow, as well as in some French cities, before the present century.<sup>249</sup> At the end of the nineteenth century, infant mortality was reported to be lower in the three rich quarters of the city of Breslau than in the three poor ones.<sup>250</sup> In the early 1920s in the United States, an infant mortality rate of about 170 per 1,000 live births was found in families where the father earned less than \$450 per year, as compared with a rate of 60 in the group where the father earned \$1,250 or more.<sup>251</sup> An inverse correlation between infant mortality and father's earnings was also found for the city of Stockholm during 1918-1922.<sup>252</sup> An analysis of mortality by income class in fourteen middle-size cities in Japan in 1939 showed that, for the most part, the higher the income, the lower the mortality, and this was especially true with respect to infant mortality.<sup>253</sup>

130. The educational attainment of the parents, especially of the mother, has also been found to have a significant relation to the level of infant mortality. A comparison of female illiteracy levels and infant mortality in twenty-seven countries for selected years in the 1930s and 1940s showed a positive correlation between the two variables.<sup>254</sup> Szabady observed that in Hungary (1959) there was a strong inverse association between parents' educational achievement and the level of infant mortality, with the mother's education having the greater influence.

<sup>248</sup> New York State, Department of Health, *The Relationship of Certain Biologic and Socioeconomic Factors* ... (1961-1963), parts 1, 2, 3; California, Department of Public Health, *Perinatal Mortality and Survival* ... (1963). In contrast, virtually no correlation between socio-economic indices and infant mortality was found in a study for the city of Bologna. Bellettini, "Le relazioni fra i fenomeni ..." (1966). Other studies presenting information on class differentials in infant mortality include the following: Federici, "Aspetti sociali della mortalità infantile a Roma" (1964); Douglas, "Social class differences in health and survival during ..." (1951); Febvay and Croze, "Nouvelles données sur la mortalité infantile" (1954); de Wolff and Meerdink, "La mortalité infantile à Amsterdam selon les groupes sociaux" (1954), pp. 293-314; Hansluwka, "Social and economic factors ..." <sup>254</sup> United Nations, *Foetal, Infant and Early Childhood Mortality*, vol. 2 ... (1954), pp. 22-23.

The infant mortality rate decreased progressively from 95 per 1,000 live births for mothers who had not attended school to 27 for those with thirteen or more years of schooling.<sup>255</sup> In Yugoslavia also, a correlation was found between infant mortality and female illiteracy. The level of health education among women was believed to be of particular importance, and although there was no way to measure this factor, the authors considered that a primary education provides the basis for obtaining health education.<sup>256</sup> In his analysis of infant mortality in France, Croze found that the cultural level—which is closely related to education—played a decisive role in social group differences in infant mortality.<sup>257</sup>

131. Some of the studies on differences in general mortality by socio-economic status have included analyses by cause of death. In the case of certain diseases, the differentials have been found not to favour the upper classes. A study for England and Wales carried out in the 1940s revealed that although pulmonary tuberculosis caused about twice as high a death rate among semi-skilled and unskilled workers as among professional and white collar workers, the mortality from diabetes mellitus, angina pectoris and appendicitis was much higher in the latter group than in the former.<sup>258</sup> Guralnick's analysis of data for England and Wales (1949-1953) and for the United States (1950) showed that while death rates from tuberculosis, malignancies, influenza and pneumonia, and motor-vehicle accidents varied inversely with status in both countries, in England and Wales, death rates specific for arteriosclerotic heart disease were much higher among the professional group than in the lower classes. There was no clear class differential for this cause of death in the United States. Social class gradients for several other causes of death were inconsistent, possibly reflecting the influence of different modes of living among different population groups. For example, drinking habits could be an important factor in establishing the pattern of death rates from cirrhosis of the liver, while dietary habits could greatly affect death rates from diabetes mellitus.<sup>259</sup>

132. Information on mortality differentials by occupation, income and education for the developing countries is sparse. The Guanabara Demographic Pilot Survey conducted in Guanabara State, Brazil, in 1961 found a slightly higher crude death rate in the lowest social class (9.1 per 1,000 population), than in the medium and highest social classes (about 8 per 1,000).<sup>260</sup> In Chile

<sup>260</sup> United Nations, *Guanabara Demographic Pilot Survey* (1964), pp. 39-40.

(1957) there were substantial differences in infant mortality between the children of labourers and those of non-labourers, with the former having 88 per cent higher mortality than the latter. The differential was considerably greater for post-neonatal mortality than for that occurring in the first month of life.<sup>261</sup> Results of the population survey of Mysore State, India, disclosed that in both the urban and rural zones surveyed, infant mortality rates varied inversely with the economic status of the household as defined by various indicators.<sup>262</sup> A 1958 survey in Nagpur District in central India provides data on child mortality according to educational attainment of father and mother. For husbands with no education, the percentage of their children having died prior to the interview was 40.4. This percentage decreased, although not regularly, with increased educational achievement, and was 27.5 for the college-educated group. The percentage of children no longer alive at the time of interview was 39.1 for wives with no schooling, 34.0 for the primary school group, and 23.7 for those with more than primary education.<sup>263</sup>

#### 4. DIFFERENTIALS AMONG ETHNIC GROUPS

133. Within any given country, different levels of mortality are frequently found among the various ethnic, racial or religious groups. Interpretation of such differences may be difficult because the needed detailed data are often lacking. For example, an analysis of the mortality rates of different religious groups would require data on the distribution of population and deaths by religion for the same time period, as well as information on the age structure of the population, in order to eliminate the effects of different age structures on mortality. The observed variations in mortality among ethnic, racial or religious groups probably reflect mainly differences in such factors as socio-economic status and accessibility of health facilities and services, rather than innate differences among the groups themselves. In view of the lack of detail in cross-classifications, however, it is rarely possible to determine the effect of these different factors.

134. In the United States, mortality has been consistently higher for the non-white as compared with the white population, and this has been true for every age group except the oldest (seventy-five years and older), and for most causes of death. In 1963, age-standardized mortality among non-whites was 47 per cent higher than among whites, compared with a differential of 58 per cent in 1900. Maternal mortality, tuberculosis, influenza and pneumonia, vascular lesions affecting the central nervous system, and homicides were among the causes showing the highest excess rates for non-whites. Suicide, on the other hand, is two to three times as prevalent among the white population. The reasons given for these differentials

"... include hereditary factors, the distribution and availability of medical facilities and services, socioeconomic factors which affect the utilization of available medical services, and the personal motivation to achieve a state of positive health".<sup>264</sup> In an earlier study for the U.S. Public Health Service, Guralnick determined that, with a few exceptions, mortality was consistently lower among white than among non-white males in the same occupation and age categories.<sup>265</sup> Mazur's estimates of life expectancy at birth for the different nationalities of the Soviet Union for 1959-1960 show a wide range from about 50 years for Chechens to 73.1 years for Latvians. He attributed these differences to the interaction of a number of economic and social factors.<sup>266</sup>

135. Ethnic differences in mortality have also been found in Asia and Africa. In Cape Town, for the period 1948-1953, the European infant mortality rate of 26.6 per 1,000 live births was only a small fraction of the non-European rate (104.8). Even greater differences were reported at ages 1-2 years. For the period 1946-1951 the mortality rate for European children was 3.0 and that of non-European children 44.0.<sup>267</sup> Economic and social conditions obviously play a major role in these differentials. Kark and Chesler found significantly lower neonatal mortality in Hindu, as compared with Zulu, communities in Durban. In the authors' view the observed differences could not be fully accounted for by general social and environmental factors, but required further study of biological and cultural factors.<sup>268</sup>

136. It seems probable that cultural factors are important in accounting for mortality differences between Malays, Chinese and Indians in the former Federation of Malaya. In 1948 the crude death rates for the three groups were about 20, 13 and 13, respectively. The fact that the Malays have not participated in the post-war mortality decline to the same extent as the Chinese and Indians has been attributed to their greater reluctance to make full use of modern health treatment and facilities.<sup>269</sup> An analysis of 1953-1954 sample census data for Burma found the Chinese and Indian minorities to have distinctly lower child mortality than the Burmese, whose probability of dying before age five was 28 per cent greater than that of the Indians and Pakistanis, and 59 per cent greater than that of the Chinese. It was suggested that the lower mortality of the Chinese might reflect their

TABLE V.17. DEATH RATES BY MARITAL STATUS AND SEX FOR SELECTED AGE GROUPS:  
UNITED STATES, 1960

(Deaths per 1,000 population in specified group)

Sex and age (in years)	Total	Single	Married	Widowed	Divorced
<i>Males</i>					
25-34 .....	1.9	3.4	1.5	6.8	5.3
45-54 .....	9.9	15.7	8.4	21.0	25.9
60-64 .....	28.6	38.0	25.3	44.0	57.0
70-74 .....	59.5	76.3	53.4	77.0	96.6
<i>Females</i>					
25-34 .....	1.1	2.0	0.9	3.0	2.2
45-54 .....	5.3	6.4	4.6	8.5	7.2
60-64 .....	15.0	14.6	13.1	18.7	17.3
70-74 .....	36.7	35.1	32.9	40.2	41.6

SOURCE: Grove and Hetzel, *Vital Statistics Rates in the United States, 1940-1960* (1968), p. 334.

relatively favourable economic position as well as cultural patterns of cleanliness conducive to good health.<sup>270</sup>

137. A comparison of mortality among the Dusun and the Chinese of the former British North Borneo showed strikingly higher child mortality among the Dusun, a primitive tribe, despite the fact that both groups live under the same climatic conditions and are exposed to similar disease hazards. The lower mortality of the Chinese was attributed to their better standards of housing, diet and cleanliness, and the better education of Chinese women, which provides them with some knowledge of hygiene and child care.<sup>271</sup>

138. Mortality in relation to marital status has long attracted wide interest. According to a comprehensive study of this subject in the United States based on 1940 data, married persons generally had the most favourable mortality, while single persons had a lower mortality than either the widowed or divorced.<sup>272</sup> Similar patterns were observed in data for 1950 and 1960 (see table V.17 for 1960 data). Lower mortality rates for married persons than for persons of other marital status were also shown by the National Mortality Survey of 1962 and 1963. The importance of socio-economic factors in establishing this differential was suggested by the fact that married persons were revealed to have completed more years of schooling than those in other marital status categories.<sup>273</sup> The substantially lower mortality noted among the married has also been attributed partly to the selection of healthier persons by marriage, and partly to the more healthful environment of family life.<sup>274</sup>

<sup>270</sup> Williams, "Infant and child mortality in Burma by ethnic group" (1966).

<sup>272</sup> United States, Bureau of the Census, *Mortality by Marital Status* ... (1945).

<sup>273</sup> United States, National Center for Health Statistics, *Socio-economic Characteristics of Deceased Persons* ... (1967), pp. 6-7.

<sup>274</sup> Dublin, Lotka and Spiegelman, *Length of Life* ... (1949), p. 137. Errors in census data and the misclassification of death certificates may also affect the observed patterns. Sheps, "Marriage and mortality" (1961).

139. The mortality pattern in England and Wales in 1959 was generally similar to that of the United States. As in the latter country, the mortality of the married was lower than that of the other marital status groups at all ages, but at ages 25-44, the mortality of the widowed and divorced combined was lower than that of the single for both males and females.<sup>275</sup> Mortality in Sweden also was found to be lower for married persons than for those in other marital status categories. As the proportion of married couples in the older age groups is expected to increase in the next few decades, the favourable mortality which the married enjoy may contribute to an over-all reduction of mortality in these age groups.<sup>276</sup>

140. Other studies have examined the relationship of marital status to causes of death. In the United States in 1940, mortality from each of the leading causes of death was found to be higher among single men than among the married, with the exception of cancer of the genital organs. Among women, on the other hand, the single had lower mortality than the married for quite a few causes of death, but widowed and divorced women had consistently higher mortality for all leading causes, with the exception of diseases of the puerperal state.<sup>277</sup> However, findings from several studies that have investigated the relationship of marital status to mortality from coronary disease are inconsistent, some results indicating an inverse relationship with marriage, and some a direct relationship.<sup>278</sup>

141. Cause-of-death differentials by marital status were also found in the 1959 data for England and Wales. Mortality from tuberculosis, poliomyelitis and chronic rheumatic heart disease was higher in single persons, partly because of the selection factor and partly because of the less protective conditions of single life. Among

women, carcinoma of the breast, corpus uteri and ovary was more common among the single, while carcinoma of the cervix uteri was a more frequent cause of death among the married and formerly married. Single males had a higher mortality from cancer of the buccal cavity, pharynx, larynx and prostate.<sup>279</sup>

#### F. Factors related to high mortality in the past

142. Before the significant fall in mortality began in Europe, North America and Oceania in the nineteenth century, death rates in these regions were high and subject to violent and recurrent fluctuations. Although the peak rates were associated with catastrophes such as war, famine and disease, the view has been expressed that the first two were often more significant for the scope which they gave to the third—disease and pestilence—rather than for their direct contribution to mortality.<sup>280</sup> In any event, the various factors making for high mortality in the past cannot be isolated, as they are often closely interwoven. Regarding famines, for example, although there are many references in the registers to deaths from starvation, it is more likely that hunger, by weakening the body, increased its susceptibility to disease rather than killing outright, except in the case of specific deficiency diseases such as scurvy. But good nutrition was no guarantee against disease. While many diseases attacked and killed those with weakened constitutions, others—such as plague and smallpox—took an equal toll of the healthy and well-nourished.<sup>281</sup> Another indirect effect of food scarcity was that during such periods rats, finding granaries empty, moved closer to the towns, creating the possibility of epidemics.<sup>282</sup> Wars affected mortality levels not merely through the number of deaths on the battlefield, but also through diseases spread by travelling armies, and through the problems posed by maintaining large numbers of soldiers without the public health facilities available to modern societies.<sup>283</sup>

<sup>279</sup> Benjamin, *Social and Economic Factors Affecting Mortality* (1965), pp. 42-43.

<sup>280</sup> Habakkuk, "English population in the eighteenth century" (1965), p. 272. This author has postulated that societies were particularly vulnerable to high death rates from disease and harvest failures after periods of rapidly increasing population, when the resources of the society were already being strained. *Ibid.*, pp. 273-274.

<sup>281</sup> Eversley, "Population, economy and society" (1965), p. 55. Numerous localized epidemics have been recorded which have not coincided with bad harvests. Reinhard, Armengaud and Dupaquier, *Histoire générale de la population mondiale* (1968), p. 147. In eighteenth-century Sweden, for example, serious crop failures were followed on occasion with only slightly higher mortality (e.g., 1726-1728, 1781-1783), while good harvests were sometimes followed by a steep rise in mortality (e.g. 1736-1738, 1779). Utterström, "Two essays on population in eighteenth-century Scandinavia" (1965), p. 545.

#### 1. FAMINES AND FOOD SHORTAGE

143. Although chronic food shortage has probably been more deadly to man, the effects of famines, being rather spectacular, have received greater attention in the literature. Because of pre-industrial man's limited control over his environment, his food supply was uneven, being affected by the vicissitudes of the weather—droughts, too much rain with its accompanying floods, prolonged winters and cold summers. Agricultural output was limited by the inefficiency of labour, by plagues of insects or rodents and by plant diseases. Even when harvests were abundant, their benefits could not be fully reaped due to inadequate methods of food storage, transportation and distribution, which hindered the movement of produce from areas of abundance to those of scarcity.<sup>284</sup> In Western Europe alone, 450 more or less localized famines were recorded from 1000 to 1885.<sup>285</sup>

144. In the 1690s poor harvests resulted in serious food shortages throughout most of Europe, with substantial repercussions on the mortality level. While important crop failures continued into the eighteenth century (e.g., 1740-1741 and the 1770s), the resultant death rates for the most part no longer assumed the catastrophic proportions of the seventeenth century, partially owing to achievements in agriculture, transportation and marketing.<sup>286</sup> That adequate food supply still remained a problem, however, is illustrated by the estimate that in the 1840s one-third of the population of the United Kingdom and Ireland subsisted on potatoes alone, and another third could add to this only coarse bread and "refuse of the shambles" twice a week.<sup>287</sup>

145. Using wheat prices as a barometer of food supply, Meuvret found them positively correlated with mortality in certain areas of seventeenth-century France. Following an agricultural crisis, wheat prices as well as deaths tripled and even quadrupled in some parts of the country in 1693-1694.<sup>288</sup> Poor harvests and crop failures—some strictly local and some more generalized—also afflicted the population in the eighteenth century, but their demographic repercussions have been difficult to measure, except in a broad sense.<sup>289</sup>

146. The Northern countries, too, suffered heavy population losses as a result of poor harvests. In the

<sup>284</sup> Thompson and Lewis, *Population Problems* (1965), pp. 387-388; Southard, "Famine" (1948).

<sup>285</sup> Southard, "Famine" (1948), p. 85.

<sup>287</sup> Stern, *Society and Medical Progress* (1941), p. 145.

<sup>288</sup> Meuvret, "Demographic crisis in France ..." (1965), pp. 513-519. In the British Isles also, a period of great hardship towards the end of the seventeenth century is believed to have checked population growth in Scotland, if not in England. Helleiner, "The vital revolution reconsidered" (1965), p. 80.

<sup>289</sup> Reinhard, Armengaud and Dupaquier, *Histoire générale de la population mondiale* (1968), pp. 241-271. For example, the widespread crop failures which followed the long harsh winter of 1708-1709 caused high mortality among the poorer classes. Helleiner, "The vital revolution reconsidered" (1965), p. 80, Chevalier, basing his discussion on Labrousse's analysis, has indicated that up to the mid-eighteenth century, France had a high death rate due to poor harvests, famines and inadequate means of communication. Chevalier, "Pour une histoire de la population" (1946), p. 249.

1690s, as much as 16 per cent of the population may have perished in certain regions of Sweden after severe crop failures, and about one-third of the inhabitants are believed to have died in one Finnish province.<sup>290</sup> An analysis of annual harvest results and vital rates for Sweden between 1740 and 1800 has shown a clear association between fluctuations in mortality levels and harvest yields, although the correlation is far from perfect due to the intervention of war years, epidemics, and other circumstances.<sup>291</sup> Thomas, who also analysed the relationship between the harvest index and mortality levels in Sweden, but for a longer period—from the mid-eighteenth century to 1914—found that in the earlier years of this period, there was a significant correlation between the two variables, with a tendency for the impact of the harvest on mortality to lessen towards the latter part of the period.<sup>292</sup> For Denmark and Finland, rye prices rather than harvest statistics have been studied in relation to eighteenth-century vital rates. According to the results of this analysis, the death rate for these countries, on the average, seems to have been 3 to 4 per 1,000 population lower in years after good, than in years after bad agricultural conditions. Despite occasional important epidemics, the main cause of the fluctuations in the death rate has been attributed to changes in the food supply. Where epidemics coincided with years of bad harvest, poor food conditions probably intensified the devastation inflicted by the diseases.<sup>293</sup> In Norway, about one-fifteenth of the total population perished in 1741, constituting a death rate more than three times higher than that of 1736-1740. The main cause is believed to have been acute crop failures in the Northern countries at that time.<sup>294</sup>

147. Among certain European countries with currently low mortality, severe famines occurred in the not too distant past. The Irish famine of 1846-1851, a result of the failure of the potato crop upon which the populace depended for subsistence, was the most disastrous one in nineteenth-century Western Europe. It killed an estimated 850,000 persons from starvation and disease in addition to the normal number of expected deaths.<sup>295</sup> Famides

were frequent in nineteenth-century Russia, and mortality was unusually high in the affected regions. For example, the crude death rate in Astrahanskaya district rose as high as 78 per 1,000 population in 1892 following a bad harvest in 1891. The economic dislocations resulting from the wars of intervention and the events surrounding them were accompanied by famines and epidemics which took a toll of millions in the period 1918-1922.<sup>296</sup>

148. Historically, famines have been frequent and devastating in a number of Asian countries. Severe famines occurred in Western Japan during the 1730s, probably contributing to the drop in population in those years, and national crop failures occurred in the 1780s and the 1830s.<sup>297</sup> In North-west China, the great drought of 1876-1879 is believed to have caused between nine to thirteen million deaths from the combined effects of prolonged hunger and the disease and violence accompanying it. Large death tolls from famine were again recorded in 1920-1921 and 1929-1930.<sup>298</sup> Davis estimated that about 19 million persons died in India during the decade 1891-1901 as a result of famines, and he refers to the "relentless recurrence of famines" in India prior to and continuing into the twentieth century.<sup>299</sup> In 1943 and 1944 there were large outbreaks of famines in Bengal and Tonkin,<sup>300</sup> and as recently as 1965-1966, poor harvests resulted in near famine conditions over wide areas of Africa and Asia.<sup>301</sup>

## 2. EPIDEMIC DISEASES

149. Mankind has apparently suffered from the ravages of infectious diseases such as typhoid, smallpox, dysentery, malaria, pneumonia, tuberculosis, typhus, yellow fever, plague, etc., as well as infants' and children's diseases such as enteritis, measles, whooping cough, scarlet fever and diphtheria, for untold centuries. These diseases, which until fairly recently took a heavy toll of human life, were rapidly spread among concentrations of persons in villages and towns by personal contact, by community use of contaminated water and food supplies, and by the migration of persons and disease-carrying insects from one population centre to another. While increased deaths from disease often followed famines, epidemic crises are also known to have occurred in the absence of famine.<sup>302</sup>

150. Until 150 to 200 years ago, scientific knowledge regarding disease was so meagre that even when methods of prevention or cure were attempted, they were usually

<sup>290</sup> Helleiner, "The vital revolution reconsidered" (1965), p. 79.

<sup>291</sup> Gille, "The demographic history of the Northern European countries ..." (1949), pp. 44-45. In Sweden during the severe famine of 1773, the death rate rose to 52.5 per thousand population. Sundbärg, *Forsatta bidrag till en svensk befolkningstatistik* (1909), vol. 10, p. 178.

<sup>292</sup> Thomas, *Social and Economic Aspects of ...* (1941), pp. 81 ff. The gradual but progressive lowering of the peaks of mortality during famines has been explained by the lessening of economic isolation among the various regions, the development of grain trade and changes in the agricultural system. These developments became pronounced during the first half of the nineteenth century. Utterström, "Two essays on population ..." (1965), p. 541.

<sup>293</sup> Gille, "The demographic history of the Northern European countries ..." (1949), pp. 45-48. According to Jutikkala, the violent fluctuations in Finland's mortality rate during the thirty years following the Great Northern War of 1700-1721 were not appreciably affected by variations in the harvest. Jutikkala, "Finland's population movement ..." (1965), p. 561.

<sup>302</sup> Habakkuk, "The economic history ..." (1965), p. 156. For a discussion of the complex relations between disease and food shortages, see Meuvret, "Demographic crisis in France ..." (1965), pp. 510-513.

ineffectual, if not actually harmful. In the sixteenth century, for example, the main remedy against plague was blood-letting, a measure which no doubt increased mortality from this disease.<sup>303</sup> Even in the seventeenth and early eighteenth centuries, the great majority of people received no medical attention, and those who did would probably have been better off without the radical purgings and bleedings administered by the medical practitioners of the times. There was little that medical men could do to cure the major ills before the advent of antiseptic surgery (mortality following surgery was extremely high), and the discovery of drugs such as salvarsan, insulin, the sulfonamides and the antibiotics.<sup>304</sup> Although many drugs for the treatment of disease were known during the eighteenth century, they were either used incorrectly or had limited efficacy in postponing or preventing death. McKeown and Brown, writing of England, have indicated that up to the early nineteenth century, the importance of segregating infectious patients in hospitals was not fully appreciated, and any patient admitted to a hospital risked contracting a mortal infection.<sup>305</sup>

151. Despite the paucity of medical knowledge, it could hardly be overlooked that some diseases such as plague, which affected great proportions of the population, must be communicable, even though the agent of transmission might be unknown. As a result, certain measures such as the setting up of protective cordons to isolate areas known to be affected were taken, though their efficacy varied.<sup>306</sup> As early as the Middle Ages, the quarantine was used in Italy, southern France and neighbouring areas to isolate patients with certain infectious diseases.<sup>307</sup>

152. Although the endemic infectious diseases, which took heavy tolls of life year after year probably had a greater effect on population growth than the occasional great epidemics, the epidemics, because of their deadliness, have attracted much attention. Europe's worst epidemic, the Black Death of 1348-1350, has been said to have killed between 25 and 35 million persons in Europe, or from one-fourth to one-third of Europe's population. Italy is reputed to have lost one-half of its population, and France and England one-third.<sup>308</sup> From 1603 to 1759, five epidemic outbreaks of plague were recorded in differ-

ent parts of Europe, always causing a tremendous rise in mortality.<sup>309</sup>

153. As certain diseases were brought under control, the virulence of others appears to have increased. Cyclical outbreaks of smallpox, which had claimed large numbers of lives before the introduction of vaccination in the nineteenth century, subsided, but a pandemic of diphtheria swept Europe from the mid-nineteenth century to the 1880s.<sup>310</sup> Although cholera had always taken its toll of life, repeated epidemics of Asiatic cholera afflicted Europe from 1831 on.<sup>311</sup> In 1918, the most severe influenza pandemic in history killed millions of persons throughout the world; one estimate places the number of persons perishing from the disease at 20 million over a period of a few months.<sup>312</sup>

### 3. WAR LOSSES

154. Although war has been an important population check throughout man's history, its precise effects on mortality have been exceedingly difficult to measure. Deaths among military personnel may occur on the battlefield, later on as a result of wounds received during combat, or from war-associated deprivation and disease. Most wars have also caused heavy civilian casualties indirectly through disease carried by armies, plunder, famine following the laying waste of agricultural lands, and other hardships accompanying social and economic disorganization. During the Second World War, civilians became the target of direct attacks on an unparalleled scale. Tremendous losses were inflicted on civilian populations through massive aerial bombings, the systematic extermination by the Nazis of Jews and certain other ethnic groups, and the decimation, under forced labour conditions, of numerous Poles, Ukrainians and other nationals. Because of problems of classifying and estimating such varied types of losses, estimates of war deaths often differ widely.<sup>313</sup>

155. Regarding the Second World War, early estimates of war-induced population losses were made by Frumkin

<sup>303</sup> Thompson and Lewis, *Population Problems* (1965), p. 394; Harsin and Hélin, "Compte-rendu des débats ..." (1965), p. 26.

<sup>304</sup> Helleiner, "The vital revolution reconsidered" (1965), pp. 83-84; Sigerist, *Civilization and Disease* (1945), p. 176.

<sup>305</sup> McKeown and Brown, "Medical evidence related to ..." (1965), pp. 286-291. It was not until well into the nineteenth century, according to these authors, "... that hospital patients could be reasonably certain of dying from the disease with which they were admitted". *Ibid.*, p. 291.

<sup>306</sup> See Sigerist, *Civilization and Disease* (1945), p. 173; Meuvret, "Demographic crisis in France ..." (1965), pp. 508-509; Harsin and Hélin, "Compte-rendu des débats ..." (1965), p. 19; Biraben, "Certain demographic characteristics ..." (1968).

<sup>312</sup> Francis, "Influenza" (1957), p. 347; for other estimates (not necessarily world-wide) of influenza mortality during the pandemic, see Thompson and Lewis, *Population Problems* (1965), p. 397; Sigerist, *Civilization and Disease* (1945), p. 236. See also Landry, *Traité de démographie* (1949), pp. 199-200.

<sup>313</sup> Among the sources which give estimates of war deaths for selected periods, or discuss problems in making such estimates, are Landry, *Traité de démographie* (1949), pp. 196-203; Thompson and Lewis, *Population Problems* (1965), pp. 421-428; Frumkin, *Population Changes in Europe since 1939 ...* (1951), pp. 9, 26-28, 158-164, 173; George, *Introduction à l'étude géographique ...* (1951), pp. 182-184; Notestein et al., *The Future Population ...* (1944), chap. 3.

after an exhaustive and painstaking analysis of all the pertinent data available to him at the time. Frumkin concluded that Europe and the Soviet Union may have sustained losses of some 30 to 35 million people as a result of the Second World War, at least 17 million in the Soviet Union and around 15 million in Europe.<sup>314</sup> Other estimates for the Soviet Union range from about 12 million to more than 20 million.<sup>315</sup> Efforts to estimate deaths attributable to the Second World War for the world as a whole are further complicated by the absence of a statistical basis for obtaining even a crude numerical assessment of the heavy casualties suffered by China.<sup>316</sup> Some recent estimates have placed the global total of military and civilian losses at more than 50 million.<sup>317</sup>

loss, dwarfs all the figures reported for the past and is a matter of continuous concern.<sup>318</sup>

#### 4. POOR CONDITIONS IN URBAN AREAS

158. As has been seen from the discussion in section E above, urban mortality was generally higher than rural in countries of Europe and Northern America prior to the twentieth century. The following is a brief summary of the reasons for this excessive urban mortality.<sup>319</sup> Cities and towns were congested, insanitary and consisted largely of overcrowded, grimy tenements gathered around the place of work. In the early industrial towns, often no provisions were made for police and fire protection, water and food inspection or hospital care. Industrial wastes were dumped into the rivers, destroying the aquatic life and polluting the water. Inside the factories, there was little ventilation, temperatures were much too hot in summer and too cold in winter, light was inadequate, hours of work were long and exhausting, and the risk of accidents was great. Such conditions caused an enormous sacrifice of life, especially among children.

159. There was an absence of zoning regulations to segregate the more noxious or noisy industries from residential areas, with the result that living quarters occupied the leftover spaces between factories, sheds and railroad yards. Whole families often occupied a single room, with as many as eight people sleeping in the same bed. The workers' houses, like the factories, had poor light and ventilation, rubbish was thrown into the streets, there was a dire lack of toilets, and cellars were used as dwelling places. This dirt and congestion attracted rodents and lice which spread diseases such as bubonic plague and typhus, and the dark, dank quarters formed an ideal breeding ground for bacteria.

160. The seepage of excrement into wells helped to spread disease, and the absence of an adequate water supply made domestic cleanliness or personal hygiene an impossibility. These conditions were reflected not only in the levels of mortality, but also in the causes of death: smallpox, typhus, typhoid, cholera and scarlet fever, because of unspeakable sanitary conditions; tuberculosis, because of poor diet, lack of sunshine and overcrowding; occupational diseases; bronchitis and pneumonia, whose incidence was increased by foul concentrations of poisonous chemicals which pervaded the atmosphere.

<sup>318</sup> A speculative study on the demographic effects of a hypothetical nuclear attack on the United States has been made by Heer, *After Nuclear Attack* . . . (1965). According to this study, an attack directed at both military and major industrial targets might be expected to kill 30 per cent of the total population of the United States, though the author points out that a fatality rate exceeding 50 per cent of the total population has been considered likely by others. *Ibid.*, p. xxiii.

<sup>319</sup> This discussion is based largely on Mumford, *The City in History* . . . (1961), pp. 458-474. See also Engels, *The Condition of the Working Class* . . . (1887); Weber, *The Growth of Cities in the 19th Century* (1899; 1963 ed.), pp. 343-367; Stern, *Society and Medical Progress* (1941), pp. 109-125; Sydenstricker, *Health and Environment* (1933), pp. 177 ff.; Cole, *The Irrepressible Conflict* . . . (1934), p. 181; Howard, *Public Health Administration and the Natural History of Disease* . . . (1924), p. 127; Meuvret, "Demographic crisis in France . . ." (1965), p. 508. Reinhard, Armengaud and Dupaquier, *Histoire générale de la population mondiale* (1968), pp. 334-335.

TABLE V.18. DEATHS OF EUROPEAN MILITARY PERSONNEL, 1600-1918

Period	Number of military deaths (millions)	Annual military death rates per 1,000 population of Europe
1600-1699 .....	3.3	0.3
1700-1788 .....	3.9	0.3
1789-1815 .....	5.0	1.0
1816-1913 .....	2.2	0.1
1914-1918* .....	9.1	5.3

SOURCE: Adapted from a table in United Nations, *The World Population Situation in 1970* (1971), p. 9. This table, in turn, is based in part on an extensive study by Ulanis of war losses in Europe. See his *Voyny i narodonaselenie Evropy* (1960), pp. 404-406.

\* Considered as a period of 4 1/4 years.

156. Considering the wide divergencies in war-loss estimates for such a recent period, figures for earlier periods, such as those in table V.18, are obviously also highly uncertain. The time periods have been selected to distinguish separately those of most intensive warfare.

157. The enormous loss of life suffered as a result of war in the twentieth century underlines the fact that of the three major causes of catastrophic mortality—famine, pestilence and war—war remains the least subject to control. In fact, advances in science and technology, which have played such an important role in the reduction of mortality from hunger and disease, continue to increase the possibilities for devastation inherent in modern warfare. The huge casualties during the Second World War resulted, for the most part, from the use of conventional armaments, and not thermonuclear weapons. The destructive potential of nuclear war, in terms of human

<sup>314</sup> Frumkin, *Population Changes in Europe* . . . (1951), pp. 9, 164, 173. These figures for the most part do not include indirect losses, i.e., "... deaths due to malnutrition and other privations brought about by war conditions". *Ibid.*, p. 26.

<sup>316</sup> Sketchy data on Chinese war losses are presented by Ho. See his *Studies on the Population* . . . (1959), pp. 249-253.

<sup>317</sup> Boyarsky et al., *Kurs demografii* (1967), pp. 346-347. Also Reinhard, Armengaud and Dupaquier, *Histoire générale de la population mondiale* (1968), pp. 570-576.

161. Ferguson has described as wretched the conditions of life in the towns of England early in the nineteenth century, citing as examples the insanitary conditions in Glasgow and London.<sup>320</sup> It is reported that in 1850 New York City had 8,141 cellars sheltering one-thirtieth of its population, and that in Boston about one-twentieth of the population lived in damp, vermin-ridden, underground rooms.<sup>321</sup>

162. While living conditions in urban areas were deplorable, there is no reason for believing that those in rural areas were much superior. On the basis of an examination of early nineteenth-century reports of a society concerned with the housing of agricultural labourers in England, Ashton expressed doubts whether the rural population was as well housed as people living in the towns. Moreover, the poor housing conditions in the rural areas also gave rise to ailments, although perhaps different ones from those prevailing in the towns.<sup>322</sup>

## G. Factors in mortality decline in developed countries

163. Some of the spectacular declines in mortality which occurred in Europe, Northern America and Oceania in the late nineteenth and early twentieth centuries have been discussed in section A above. The factors responsible for these declines are numerous, although at times elusive. In discussing them, different writers have devised different classification schemes, the simplest being a twofold division between factors which are mainly related to economic and social development, and those related to advances in medical science, public health and sanitation.<sup>323</sup> In other classifications public health measures and improved sanitation have been included with other "environmental" factors, and distinguished from improvements in preventive and curative medicine.<sup>324</sup> Some more extensive classifications, such as that provided by Carr-Saunders, have identified improvements in sanitation as a separate category.<sup>325</sup>

164. Whatever the broad categories used for analysis, it is clear that underlying the multitude of individual factors responsible for the reductions in mortality have been the more or less continuous economic advances resulting from the so-called agricultural and industrial

revolutions; this progress made possible the development and applications in technology, public health, sanitation and medicine which were crucial for substantial mortality decline.

165. Statistical analyses which attempt to quantify the influence of the various factors affecting mortality are rarely found in the literature. Because of data deficiencies, the imprecision of analytical tools, and the inherent difficulties resulting from the mutual interdependence of factors, it is not possible to measure separately the effects of such diverse factors as improvements in nutrition, housing, environmental sanitation, personal hygiene, and medical knowledge and services, or the increasing health consciousness of the people. It is even less feasible to isolate the effects of various underlying economic and social changes such as the rise in real wages, the improvement of agricultural techniques, the development of transportation facilities or the enactment of specific laws relating to employment conditions, housing, etc.<sup>326</sup>

## 1. ECONOMIC DEVELOPMENT AND RISING INCOME LEVELS

166. While the substantial declines in mortality in the now industrialized countries took place only after the middle of the nineteenth century, trend data show that a slow, though irregular, mortality fall began much earlier. This trend during the eighteenth and early nineteenth centuries resulted not so much from a decline in the general death rates as from a lowering of the peaks of mortality which, during famines and epidemics, had periodically swept away the accumulation of many years' natural increase.<sup>327</sup> These declines in catastrophic mortality had already begun prior to industrialization,<sup>328</sup> and have been attributed to the fact that subsistence crises in agriculture occurred less frequently and were less often followed by epidemic diseases.<sup>329</sup> The main underlying causes include a complex of factors associated with improvements in the level of living and environment.<sup>330</sup>

<sup>320</sup> Ferguson, "Public health ..." (1964), pp. 213-214. Recent studies of housing and sanitary conditions in urban communities of the United Kingdom, documenting the effects of these conditions upon health and mortality, are as follows: Glass, "Some indicators ..." (1964), pp. 263-267; and Benjamin, "The urban background ..." (1964), pp. 225-248.

<sup>321</sup> Stern, *Society and Medical Progress* (1941), p. 110.

<sup>322</sup> Ashton, "Some statistics of the Industrial Revolution in Britain" (1966), p. 242.

<sup>323</sup> Stolnitz, "A century of international mortality trends, I" (1955), p. 29; Thompson and Lewis, *Population Problems* (1965), p. 429.

<sup>324</sup> McKeown and Brown, "Medical evidence ..." (1965), p. 304. The authors also added a third category to account for changes in the virulence of infective organisms.

<sup>325</sup> Carr-Saunders's classification was as follows: (1) political, that is the maintaining of external and internal order; (2) social, including advances in the production and use of food and clothing; (3) sanitary, including improvements in housing, drainage and water supply; and (4) medical, including the application of known measures for the prevention and cure of disease to the public at large. Carr-Saunders, *World Population* ... (1936), p. 75.

<sup>326</sup> See, for example, Ariès, *Histoire des populations françaises* ... (1948), p. 527; United Kingdom, Royal Commission on Population, *Report* (1949), p. 18; Dublin and Lotka, "Trends in longevity" (1945); Veselovsky, *Kurs ekonomiki* ... (1945), pp. 172, 506; and Sautin, "Pod'em materialnogo i kulturnogo urovnia ..." (1939), p. 115. On the difficulties of measuring the influence of different factors on mortality, see Benjamin, *Social and Economic Factors Affecting Mortality* (1965), pp. 5-14; Buckatzsch, "The influence of social conditions ..." (1947). The controversy regarding the reasons for early mortality decline in Britain is also discussed in chapter XIV, section B.

<sup>327</sup> Utterström, "Two essays on population ..." (1965), p. 541; Helleiner, "The vital revolution reconsidered" (1965), p. 85; Henry, "The population of France ..." (1965), p. 448. In some parts of Italy, these checks to population growth became more and more rare after 1820. Cipolla, "Four centuries of Italian demographic development" (1965), p. 575.

<sup>328</sup> Harsin and Hélin, "Compte-rendu des débats ..." (1965), pp. 42-43.

<sup>329</sup> See, for example, Thomas, *Social and Economic Aspects of* ... (1941), p. 87; Henry, "The population of France ..." (1965), pp. 447-448; Eversley, "Population, economy and society" (1965), p. 61; Habakkuk, "The economic history ..." (1965), p. 157.

<sup>330</sup> See, for example, Eversley, "Population, economy and society" (1965), p. 57; McKeown and Brown, "Medical evidence related to ..." (1965), pp. 305-307. The rising level of living is said to have begun affecting British mortality at least as early as 1770. McKeown, "Medicine and ..." (1965), p. 1076.

167. One of the favourable developments affecting the mortality of European peoples since the eighteenth century has been an improvement in the supply of food and in diet. Farming methods and implements were very primitive prior to the Agricultural Revolution, which began in England and several other European countries around 1700 and spread throughout Europe and to European overseas settlements. Changes in the systems of land tenure and crop rotation, the development of improved strains of plants and animals, and the introduction of new crops and better farm machinery, began to increase the productivity of labour and of land, and reduced the risks of crop failures, resulting in a steadier supply of food. It thus became possible to reduce mortality which may previously have been caused by chronic insufficiency of the food supply, and to create surpluses for the support of a rapidly growing population.<sup>331</sup> Further technological advances in agriculture during the nineteenth and twentieth centuries, including the use of artificial fertilizers and finally the mechanization of agriculture, brought the major nations of Europe, Northern America and Oceania to the point where they could feed themselves with a declining proportion of their labour force employed on the land. The workers thus freed from the necessity of producing food turned to the production of a multitude of other goods and services which enabled them to prolong and enrich their lives as well as the lives of agricultural workers.

168. Technological advances in transportation, such as the invention and development of the steam engine, also contributed to a more reliable food supply by facilitating the movement of food from areas of plenty to those of scarcity, thus mitigating the effects of local harvest failures and consequent famines and epidemics. The improved means of transportation, by making easier the exchange of agricultural commodities both internally and between countries, increased the commercialization of crops, with America becoming an important supplier of grain. In addition, better methods of storing food reduced the waste formerly characteristic in years of abundant harvests, by permitting the storage of certain commodities for use during leaner years.<sup>332</sup>

169. Although large numbers of people lived under conditions of misery and pauperism, especially in the early stages of industrialization,<sup>333</sup> gradual increases in real wages in the long run contributed to a better nourished

population.<sup>334</sup> While there have been few studies of the relation of nutritional improvement to mortality decline, it has been suggested that a better diet was probably the main cause of the substantial fall in tuberculosis mortality in England and Wales during the second half of the nineteenth century, and was probably a factor, although to a lesser extent, in the decline of mortality from typhus.<sup>335</sup>

170. The advances in technology and in levels of living affected health favourably in a number of other ways. More adequate housing was constructed, better clothing became available, and health services and medical research were extended.<sup>336</sup> Some measures directly concerned with sanitation and hygiene are discussed below.

## 2. SANITARY REFORMS AND PUBLIC HEALTH MEASURES

171. While the earliest mortality declines resulted mainly from causes associated with general improvements in the level of living, after the middle of the nineteenth century, sanitary reform and public health movements were increasingly important factors.<sup>337</sup> The modern concern of Governments as well as private agencies with public health is an outgrowth of the sanitary reform movement which began in nineteenth-century England as a reaction to the many evils arising from the Industrial Revolution. In the early stages of the movement, care was taken to prevent excessive intrusion by the State upon personal liberty, in accordance with the predominant *laissez-faire* philosophy, but as time went on, State intervention in health matters became broader.<sup>338</sup>

172. Even before the microbial origins of infectious disease were established, the relationship of filth and congestion to disease had been observed, and cleanliness on a community, as well as a personal level, became a central feature of the hygienic movement.<sup>339</sup> Edwin Chadwick, an early leader of the sanitary reform movement in England, published his monumental *Report on*

<sup>334</sup> In England, for example, food was very much cheaper in real terms in 1850 than it had been a century before, and after 1870 prices fell further as a result of imports. Eversley, "Population, economy and society" (1965), p. 61. As an example of increased consumption of foodstuffs, between 1850 and 1860 the average Frenchman is said to have consumed 187 kilogrammes of wheat, 77 litres of wine and 4 kilogrammes of sugar; between 1900 and 1910 the corresponding quantities had been raised to 234 kilogrammes, 141 litres and 14 kilogrammes, respectively. Reinhard and Arment-gaud, *Histoire générale de la population mondiale* (1961), p. 263.

<sup>335</sup> McKeown and Record, "Reasons for the decline of mortality ..." (1962), pp. 119-120; see also McKeown, "Medicine and world population" (1965), pp. 1072-1074. Pending further research, one writer has tentatively attributed to nutritional reasons most of the nineteenth-century mortality improvement. Anderson, "Age-specific mortality in selected Western European countries ..." (1955), p. 249.

<sup>336</sup> See, for example, Eversley, "Mortality in Britain ..." (1965), pp. 363-364.

<sup>337</sup> According to McKeown, sanitary measures became the main factor in advances in health in Britain from about 1870. McKeown, "Medicine and world population" (1965), p. 1076.

<sup>338</sup> Rosen, "Public health" (1968), pp. 167, 169.

<sup>339</sup> See, for example, Sigerist, *Civilization and Disease* (1945), p. 27; Mumford, *The City in History* ... (1961), pp. 474-475; Rosen, "Public health" (1968), pp. 167 ff.; Spiegelman, "Mortality in the United States ..." (1968), p. 526.

<sup>331</sup> See, for example, Thompson and Lewis, *Population Problems* (1965), pp. 402-404, 410, 414; Thomas, *Social and Economic Aspects of ...* (1941), pp. 51-52; Carr-Saunders, *World Population ...* (1936), p. 76; Harsin and Hélin, "Compte-rendu des débats ..." (1965), p. 36; Eversley, "Mortality in Britain ..." (1965), p. 366.

<sup>332</sup> See Dorn, "Mortality" (1959), p. 455; Thompson and Lewis, *Population Problems* (1965), pp. 404-405, 412, 416; Thomas, *Social and Economic Aspects of ...* (1941), pp. 73-74, 87-88; Harsin and Hélin, "Compte-rendu des débats ..." (1965), p. 39; Eversley, "Mortality in Britain ..." (1965), pp. 365-366.

<sup>333</sup> See, for example, Taylor, "Progress and poverty in Britain ..." (1966); Krause, "Changes in English fertility and mortality, 1781-1850" (1958), p. 65; Hobsbawm, "The British standard of living, 1790-1850" (1957). According to this author, some 10 per cent of the total population of Britain in the early 1840s were probably paupers. *Ibid.*, p. 53.

the Sanitary Condition of the Labouring Population of Great Britain in 1842, showing the relationship between filthy environmental conditions and disease. The following year a Royal Commission was appointed to study health conditions in urban areas, and in 1848 Parliament passed the first Public Health Act. This was an important landmark in the modern public health movement. It not only established the General Board of Health, creating a basis for future progress in public health administration, but also influenced public health far beyond England's shores, particularly in the United States. From 1855-1876, Chadwick's work was carried on by John Simon, whose writings set down the principles upon which nearly all subsequent public health work has been based.<sup>340</sup> Although mortality levels in Britain did not show much change during the first years of interest in sanitary reform and public health, a steady but slow decline amounting to about 30 per cent occurred between 1871-1901, a period which witnessed the introduction of new compulsory public health legislation, as well as economic and social advances.<sup>341</sup>

173. In the United States an early proponent of communal responsibility for health was Lemuel Shattuck, who, after a sanitary survey in Massachusetts in 1849, urged the creation of a State Health Department. It was not until 1869, however, that his suggestion was adopted. This event, together with the establishment of the New York Metropolitan Board of Health three years earlier, were landmarks in the development of American public health, and served as important guides in the establishment of other state and municipal health departments which followed soon after.<sup>342</sup>

174. The work of the sanitary reformers led to various concrete measures for the improvement of environmental sanitation. Public agencies for refuse removal began operations in London in 1848. In 1865, the London Metropolitan Board of Works provided a new network of sewers which permitted the abandonment of cesspools and open ditches. The purification of the water supply began on a small scale in the first half of the nineteenth century in Paris and London, but it was not until the last quarter of the century that public water systems and the filtering of water became widespread in the big cities of Europe and the United States.<sup>343</sup> By the beginning of the twentieth century, most of the cities of the Western world and of Russia had introduced systems of refuse removal and had greatly increased the purity of their water supplies.<sup>344</sup> The disinfection of water through chlorination came into use after the turn of the century and provided a more effective method of water treatment

than filtration.<sup>345</sup> As a result of the improvements in public sanitation, mortality rates from the bowel diseases (cholera, dysentery, diarrhoea), and typhoid, declined to a small fraction of their former levels.<sup>346</sup>

175. Along with the advances made in environmental sanitation, there was also greater concern with personal hygiene.<sup>347</sup> Soap, which had been taxed as a luxury throughout the centuries, came into more common use in the nineteenth century. The substitution of cotton for woollen undergarments may also have contributed to personal hygiene because of the relative ease of washing cotton clothing.<sup>348</sup> The growing concern with personal hygiene is considered to have been an important factor in the disappearance of typhus, which is transmitted by the body louse.<sup>349</sup>

176. Other measures designed to promote the health of the population were gradually introduced. Notification of the more important infectious diseases was made compulsory and quarantine was imposed where deemed necessary. There was an increase in the number and quality of hospitals and tuberculosis sanatoria. Community health departments and boards of health were established, and health visitor services were provided to advise mothers in hygiene, nutrition and the physical development of their young offspring. Medical consultation services were made available for pre-school children and routine medical examinations for school children.<sup>350</sup>

### 3. SOCIAL REFORM

177. In addition to the reforms oriented specifically toward disease control, the nineteenth century saw the introduction of important measures to improve living and working conditions in England and a number of other countries undergoing industrialization. Since that time a mass of legislation has been enacted dealing with various aspects of man's environment which may affect his health and well-being, directly or indirectly. In Britain a series of Factory Acts beginning as early as 1802 and continuing into the mid-twentieth century, gradually raised the minimum age of employment, shortened the length of the working day, and sought to improve physical working conditions and reduce industrial

<sup>345</sup> Wolman, "Water purification" (1957).

<sup>346</sup> See, for example, McKeown, "Medicine and world population" (1965), p. 1073; Newsholme, *Evolution of Preventive Medicine* (1927), pp. 132-133.

<sup>347</sup> Sigerist, *Civilization and Disease* (1945), p. 27.

<sup>348</sup> Buer, *Health, Wealth and Population* . . . (1926), pp. 196-197; on the use of soap in personal hygiene, see also Mumford, *The City in History* . . . (1961), pp. 468-469. Krause has pointed out, however, that it is not known with certainty that the cotton clothing was actually washed more frequently, and the increased production of soap could have been for industrial use. See his "Changes in English fertility . . ." (1958), p. 65.

<sup>349</sup> McKeown, "Medicine and world population" (1965), pp. 1072-1073.

<sup>350</sup> Some of these measures as they relate to Britain are discussed in Benjamin, "The urban background . . ." (1964). In Britain, milk depots which made clean cows' milk available for infants began to be opened around the turn of the century. *Ibid.*, p. 239; this and other efforts to improve the care of infants was followed by a decline in infant mortality. Lessof, "Mortality in New Zealand . . ." (1949), p. 77.

accidents. British factory legislation served as a model for similar legislation elsewhere.<sup>351</sup>

178. Among the landmark housing legislation enacted in Great Britain were the Shaftesbury Acts of 1851 which provided statutory authority to condemn unfit houses and to impose occupancy standards in the interest of public health. On the Continent, France passed an act in 1850 which provided authority to improve insanitary housing. An act authorizing the condemnation of unfit houses was drawn up in Naples in 1885, following a severe cholera epidemic. Similarly, in Belgium (1889), Holland (1901) and the United States (1901) significant housing measures were enacted.<sup>352</sup>

179. Among other social measures contributing to improved health (and therefore to lower mortality) have been social security schemes providing such benefits as old-age pensions, health insurance, medical care, unemployment insurance and payments to the indigent. In some countries of Europe, voluntary groups such as trade unions undertook schemes to protect their members from the financial hazards of accidents and illness long before the establishment through legislation of national social insurance systems. The earliest State systems usually provided for benefits to industrial workers in case of accident or illness, but gradually the coverage became broader.<sup>353</sup>

180. Compulsory health insurance for workers was introduced in Germany in 1883, and subsequently in a number of other Western countries;<sup>354</sup> Germany was also first to adopt a comprehensive old-age retirement plan (1889).<sup>355</sup> In Britain old-age pensions on a limited scale and industrial health insurance were introduced in 1908 and 1911. After the Second World War health and welfare services were considerably broadened, and the National Health Service Act offered, beginning in 1948, free comprehensive medical care to all wishing to avail themselves of it.<sup>356</sup> In the Soviet Union free and comprehensive health services, as well as a broad range of social benefits, are provided by the State. In the period 1913-1964 there was a twelvefold increase in the ratio of doctors to population. These are among the factors contributing to the sharp mortality decline from 29.1 deaths per thousand population in 1913 to 7.2 in 1963.<sup>357</sup> The first national programme of social insurance in the United States was embodied in the Social Security Act of 1935, which established a comprehensive nationally

operated plan of old-age insurance and made available Federal grants-in-aid for various programmes on the State level, such as public health services.<sup>358</sup>

181. The institution of free and universal compulsory schooling, resulting in mass literacy, and the inclusion of lessons in personal hygiene in the school curriculum, have created a greater awareness of health matters among the population, encouraging the application of basic good health practices, and leading to earlier recognition and treatment of disease.<sup>359</sup>

#### 4. ADVANCES IN MEDICINE

182. The point in time at which the contribution of medicine became an important factor in mortality decline has been a matter of debate. McKeown, Brown and Record have challenged the traditional belief that the substantial increase in population in Britain prior to the twentieth century owes much to the work of doctors in bringing about mortality decline. They believe that, with the exception of smallpox vaccination, the course of mortality could not have been significantly affected by medical practices before the twentieth century. Although there had been earlier important advances in the knowledge of anatomy, physiology, and morbid anatomy, they had no practical significance from the patient's point of view until they could contribute to the preservation of health or recovery from illness. While the discovery of several kinds of anaesthesia in the nineteenth century increased the scope of surgery, it did not increase its safety until antiseptic surgery came into widespread practice.<sup>360</sup>

183. There is some evidence that improved medical practices, aside from smallpox vaccination, did make a contribution—however modest—to mortality decline before the twentieth century. For example, around the middle of the last century, Semmelweis introduced the practice of antiseptic precautions during childbirth, abruptly reducing maternal mortality. In his own practice, mortality from puerperal fever declined from 10 per cent to 1 per cent.<sup>361</sup> Eversley has mentioned the possibility that the best medical practice of the day may have saved some lives among the upper classes.<sup>362</sup>

<sup>358</sup> Watt, "Social security and the workers . . ." (1938), p. 716; Pribram, "Social insurance in Europe . . ." (1937).

<sup>359</sup> See, for example, Benjamin, "The urban background . . ." (1964), p. 248.

<sup>360</sup> See McKeown and Brown, "Medical evidence related to . . ." (1965); McKeown and Record, "Reasons for the decline of mortality . . ." (1962); McKeown, "Medicine and world population" (1965). Anderson, too, has suggested that medicine contributed little or nothing to mortality improvements during the nineteenth century. See his "Age-specific mortality in selected Western European countries . . ." (1955), p. 249. The importance even of smallpox vaccination in early mortality decline is a subject of debate. Krause, writing of England, has indicated that there was no widespread system of free vaccination until the 1840s, and as late as 1889 medical opinion was not unanimous as to its value. Krause, "Changes in English fertility and mortality, 1781-1850" (1958), p. 63.

184. It is beyond the scope of this chapter to chronicle the numerous achievements in medical therapy which have recently contributed so much to mortality reduction, in some cases eliminating completely from the developed countries mortality from certain dread diseases of only a century or less ago. However, some of the most significant medical advances are summarized below.<sup>363</sup> It should be kept in mind that substantial time periods often elapsed between a medical discovery and its being put into widespread practice. Such time lags may have resulted from inertia or resistance to innovation; from the slow dissemination of knowledge; or from the lack of adequate resources for taking the required medical action. Some of these factors are especially important in the present-day developing countries.

185. At the end of the eighteenth century (in 1798), Edward Jenner published his famous essay presenting evidence that inoculation for cowpox prevents smallpox. However, prior to the work of the great bacteriologists in the latter part of the nineteenth century, little was known of the role of pathogenic organisms in the causation of disease, although an awareness existed of a relation between filth and infectious disease. Progress in the prevention and control of these diseases could only proceed from a scientific knowledge of their nature and causes. One of the giants of this period was Louis Pasteur, whose pioneer researches proved that micro-organisms were not spontaneously generated, and established the microbial origin of infectious diseases. His work had important repercussions on surgery and the sterilization of food products, especially milk (which contributed greatly to the reduction of infant mortality). During the same period, the bacteriological investigations of Robert Koch resulted in his isolation of the organisms causing anthrax, plague and Asiatic cholera, but his most momentous discovery was the identification of the tubercle bacillus in 1882. In the area of preventive medicine, he developed a method of inoculation against anthrax. Together, the work of Pasteur and Koch laid the foundations for modern bacteriology and the science of immunization. In 1883, Ilya Mechnikov discovered phagocytes and his views on their importance in protecting the body against infectious agents were firmly established by 1892. Dmitri Ivanovski's discovery of the virus towards the end of the century expanded knowledge of the agents causing infectious diseases, giving further scope to progress in immunology.

<sup>363</sup> The discussion is based on the following sources: American Medical Association, *Commission on the Cost of Medical Care, Significant Medical Advances* ... (1964); Benenson, *Control of Communicable Diseases* ... (1970); Benjamin, "The urban background ..." (1964); Cruickshank, "The background to immunization" (1961); Dublin, Lotka and Spiegelman, *Length of Life* ... (1949), pp. 150-166; Edsall, "Efficacy of immunization procedures ..." (1961); Sigerist, *Civilization and Disease* (1945); Spiegelman, "Mortality in the United States ..." (1968); Thompson and Lewis, *Population Problems* (1965), pp. 433 ff.; United States, National Center for Health Statistics, *Changes in Mortality Trends* ... (1965); Zhdanov, "Immunization in communicable disease control" (1961); and the appropriate subject headings in the *Encyclopaedia Britannica* (1957) ed.) and in *Bolshaia sovetskaia entsiklopediia* (1949-1958). See also the following World Health Organization publications: *Research in Immunology* ... (1964); *WHO Expert Committee on Tuberculosis* ... (1964); *The Use of Human Immunoglobulin* ... (1966); *Human Viral and Rickettsial Vaccines* ... (1966).

186. Among other important medical advances in and around the second half of the nineteenth century were Joseph Lister's introduction of antiseptic surgery in 1865, which, together with William Morton's use of anaesthesia around the middle of the century (1846) eventually revolutionized surgical practice. In the 1890s, Emil von Behring's researches produced effective immunizing agents against tetanus and diphtheria, and Wilhelm Röntgen's discovery of the X-ray in 1895 provided the physician with an important tool for diagnosis, as well as for the treatment of certain diseases. An early contribution to curative, as opposed to preventive, medicine was Paul Ehrlich's discovery of salvarsan in 1910, a compound which was highly effective against certain types of protozoa, including the infectious agent causing syphilis.

187. The research in immunology and bacteriology in the late nineteenth century bore important fruit in the twentieth century, especially the second quarter, with the development of preparations for immunization against many infectious diseases, and for their cure once the disease had taken hold. Among the important diseases for which immunizing agents were available by the 1960s, aside from the ones already mentioned, were tuberculosis, typhoid fever, typhus fever, cholera, yellow fever, measles, whooping cough, poliomyelitis, plague and influenza. In certain diseases vaccination is the only satisfactory method of control, whereas in others it is merely an auxiliary method.

188. Great strides in chemotherapy (i.e., the use of drugs to cure or halt the progress of an infectious disease) began in the late 1930s with the widespread use of the sulfonamides in the treatment of respiratory and urinary tract infections, certain types of meningitis, and other infections. Penicillin, which came into widespread use among civilians after the Second World War, has been especially effective against infections of the respiratory and genito-urinary tracts, but also has been useful in other infections. The most important anti-tuberculosis drugs—streptomycin, para-aminosalicylic acid (PAS) and isoniazid—were introduced in the mid-1940s and early 1950s. Other important broad-spectrum antibiotics, such as the tetracyclines and chloramphenicol, also came into use after the Second World War. They are highly effective against a wide variety of infectious diseases, including plague and typhoid fever. As a consequence of these developments in drug therapy, mortality from many infectious diseases declined to a new low.

189. The use of pharmaceuticals in the treatment of non-infectious diseases has also contributed to mortality decline in the present century. One such group of drugs is the hormones, which consist of different types of glandular extracts administered in certain deficiency diseases, e.g. insulin to diabetics, and thyroid and liver extracts to persons suffering from thyroid deficiency and pernicious anaemia, respectively.

190. As improved medical treatment is only one among many factors affecting mortality trends, its contribution to mortality decline is difficult, if not impossible, to assess. However, in certain cases medical intervention can be reasonably assumed to have played a major role in mortality decline from specific diseases. For example,

TABLE V.19. DEATHS FROM RESPIRATORY TUBERCULOSIS IN SELECTED COUNTRIES, 1947 AND 1967

Country	Number of deaths		Deaths per 100,000 population		Percentage decrease in death rate 1947-1967
	1947	1967	1947	1967

United States .....	44,462	6,351	31.0	3.2	89.7

SOURCES: United Nations, *Demographic Yearbook, 1951 ... (1951), table 22; ——— 1968 ... (1969), table 20.*

<sup>a</sup> For 1966.

<sup>b</sup> For 1947-1966.

in England and Wales, an intensive national immunization campaign against diphtheria was begun in 1940-1941. By 1949, diphtheria mortality had fallen by 98 per cent, and ten years later no deaths occurred from this cause.<sup>364</sup> The complete eradication of smallpox has been accomplished in many countries through widespread immunization of the population with high-quality vaccines, and the maintenance of the immunity by periodic revaccination.<sup>365</sup> Vaccination against poliomyelitis gives excellent protection against the disease, which has decreased dramatically, or even disappeared, in countries where immunization has been systematic.<sup>366</sup> In the United States, for example, the number of deaths from poliomyelitis dropped from 1,368 in 1954, the year before immunization began, to 16 in 1967.<sup>367</sup>

191. A large portion of the substantial decline in tuberculosis mortality following the Second World War has been attributed to the introduction of anti-tuberculosis drugs. In England and Wales, for example, a dramatic reduction in mortality from tuberculosis followed the introduction of specific chemotherapy with streptomycin in 1947-1948, and the decline continued as new drugs subsequently became available.<sup>368</sup> Table V.19 shows the recent trend in deaths from respiratory tuberculosis for selected countries.<sup>369</sup>

192. Among the non-pharmaceutical medical advances which have contributed to lowered mortality are new and improved diagnostic techniques, making possible the detection of disease at an early and curable stage. An

example of such a technique is the vaginal smear ("Pap" test, after George N. Papanicolaou, who first published a report on its use in 1928, and was co-author of "The diagnosis of uterine cancer by the vaginal smear" in 1943). In the United States, the age-standardized death rate for uterine cancer decreased from 27.5 to 13.6 per 100,000 women during 1930-1960. Improved surgical and radiological treatment also contributed substantially to the decline, but it is believed that early detection through annual examinations can virtually eliminate mortality from this type of cancer.<sup>370</sup>

193. The development of effective insecticides with residual action has greatly reduced mortality from insect-borne diseases such as typhus and malaria. The most common of these insecticides is DDT, which was widely used during the Second World War, and dramatically proved its effectiveness in the prevention of malaria and typhus among military personnel. The latter disease had been a deadly companion of armies as late as the First World War. Since 1945 anti-malarial campaigns, in which DDT figured prominently, have practically wiped out the disease in many areas where it was once endemic (see section H). Other insecticides have been developed for use where resistance to DDT has occurred among the vectors.<sup>371</sup>

## 5. "NATURAL" FACTORS

194. Among the factors mentioned as having contributed to mortality decline from certain diseases have been a change in the virulence of the disease-causing organism or in the resistance of the human host, or both. Mortality from smallpox, scarlet fever and diphtheria, and possibly some other diseases, is believed by certain writers to have been favourably affected by such changes.

<sup>364</sup> United States, National Center for Health Statistics, *Changes in Mortality Trends ... (1965), p. 37.*

<sup>365</sup> Zhdanov, "Immunization in communicable disease control" (1961), p. 9.

<sup>366</sup> World Health Organization, *Human Viral and Rickettsial Vaccines ... (1966), p. 39.*

<sup>367</sup> American Medical Association, Commission on the Cost of Medical Care, *Significant Medical Advances ... (1964), p. 34; United Nations, Demographic Yearbook, 1968 ... (1969), p. 420.*

<sup>368</sup> United States, National Center for Health Statistics, *Changes in Mortality Trends ... (1965), p. 38.*

<sup>369</sup> Trends in death rates from all types of tuberculosis for twenty-one countries in the period 1952-1953 to 1960-1961 are given in Tsukahara, *Trends in Age-adjusted ... (1966), p. 386.*

<sup>370</sup> American Medical Association, Commission on the Cost of Medical Care, *Significant Medical Advances ... (1964), pp. 47-57.*

<sup>371</sup> Sigerist, *Civilization and Disease (1945), pp. 118-122; Dublin, Lotka and Spiegelman, Length of Life ... (1949), pp. 149-150; Thompson and Lewis, Population Problems (1965), p. 434; Benenson, Control of Communicable Diseases ... (1970), pp. 141-142, 275-278.*

Although the effects of these factors are difficult to measure, they are not believed to have been of major importance in the over-all mortality decline under analysis.<sup>372</sup>

195. Regarding smallpox, for example, it has been noted that its virulence had been declining not only before vaccination became compulsory, but even before the publication of the results of Jenner's studies on the subject. This is not, however, to suggest that vaccination has not played a major role in the eradication of the disease.<sup>373</sup> The change in scarlet fever during the nineteenth and twentieth centuries from a serious killer to a relatively mild disease is believed to be due in large measure to a lowered virulence of the causal streptococcus, rather than to environmental or medical factors, especially as the disease had gone through several cycles of varying severity in the past. Moreover, in contrast to earlier periods, scarlet fever now tends to attack older children and adults, who have greater powers of resistance than younger children.<sup>374</sup> In his analysis of mortality trends for specific infectious diseases in a number of Western European countries during the first half of the present century, Pascua concludes that the great declines in mortality from diphtheria cannot be explained by medical practice, and that a change in the infective organism or in human resistance to the disease, or in both, has probably taken place, even though the nature of the changes is not understood.<sup>375</sup> The reasons for the disappearance of epidemics of one of the biggest killers—plague—from Western Europe since the mid-seventeenth century (except for the relatively localized epidemic in southern France in 1720-1722) remain a mystery, although a number of theories, unrelated to economic or medical progress, have been advanced.<sup>376</sup>

<sup>372</sup> Habakkuk suggests, for example, that the effects on mortality of inadequate food supplies in late eighteenth-century England were less severe than formerly, principally because the diseases usually following such scarcities were milder. Habakkuk, "The economic history ..." (1965), p. 157. McKeown and Record estimate that a change in the character of certain infectious diseases may have been responsible for roughly between one-fifth and one-third of mortality decline in England in the latter half of the nineteenth century. McKeown and Record, "Reasons for the decline of mortality ..." (1962), p. 119. Pascua maintained that the role of possible changes in pathogenicity of the causal agents in mortality decline in Europe during the first half of the twentieth century could not be appraised. Pascua, "Evolution of mortality ..." (1951), p. 137.

<sup>373</sup> On this subject, see Eversley, "Mortality in Britain ..." (1965), pp. 361-362; Harsin and Hélin, "Compte-rendu des débats ..." (1965), p. 23; McKeown and Record, "Reasons for the decline of mortality ..." (1962), p. 97; Pascua, "Evolution of mortality ..." (1951), p. 133.

<sup>374</sup> McKeown, "Medicine and world population ..." (1965), p. 1073; McKeown and Brown, "Medical evidence related to ..." (1965), p. 304; Dublin, Lotka and Spiegelman, *Length of Life* ... (1949), pp. 157-158; Pascua, "Evolution of mortality ..." (1951), pp. 70-72.

<sup>375</sup> Pascua, "Evolution of mortality ..." (1951), pp. 104-111. Although immunization programmes were carried out in some areas, diphtheria mortality also decreased significantly in countries where the number of immunizations was inconsequential. *Ibid.*, pp. 109-111.

## H. Factors in mortality levels and trends in developing countries

### 1. FACTORS IN RECENT MORTALITY DECLINE

196. As in the developed countries, the factors affecting mortality in developing countries have been classified differently by various writers, although generally the classifications permit a distinction between the broad categories of socio-economic factors on the one hand, and medical and health factors on the other.<sup>377</sup> Most analyses have stressed the fact that the rapid decline in mortality in developing countries during the past several decades has been largely independent of economic conditions. Though an inverse correlation still exists between levels of economic development and mortality, the linkage between the two has been considerably weakened.<sup>378</sup> The declines have rather been attributed mainly to technological advances in the prevention and control of disease and the growth and expansion of public health and medical services.<sup>379</sup>

197. Among the most important discoveries were insecticides like DDT, antibiotics like penicillin, and vaccines like BCG (*Bacillus Calmette-Geurin*). Owing to increased scientific communication and co-operation among nations, it has proved possible for developing countries to import techniques developed in the industrialized countries and to apply them in mass public health programmes at relatively small cost, often with the assistance of international agencies, such as the World Health Organization.<sup>380</sup>

198. The above view of the principal factors in recent rapid mortality declines is supported by the results of a study of mortality change in Latin America carried out by Arriaga and Davis. They found that up to 1930, declines in death rates progressed at a modest pace with economic development in some of the more advanced

<sup>377</sup> Bourgeois-Pichat and Pan, for example, considered the relative influence of socio-economic factors and the level of living as opposed to that of the state of medicine and public health. See their "Trends and determinants of mortality in underdeveloped areas" (1956), pp. 23-25. Robinson's classification distinguished between "medical" and "socio-economic" factors, the latter including also the expansion of health facilities and environmental improvements. Robinson, "Recent mortality trends in Pakistan" (1957), p. 7.

<sup>378</sup> United Nations, *Population Bulletin of the United Nations*, No. 6 ... (1963), pp. 10-11; Sauvy, *Malthus et les deux Marx* ... (1963), pp. 64-68. Stolnitz pointed out that rapid mortality decline has taken place during periods of relatively slight economic growth (as in Ceylon), as well as during periods of relatively rapid economic growth (as in Mexico). Stolnitz, "Recent mortality trends ..." (1965), p. 117. See also Glass, "Population growth and population policy" (1965), p. 1090; National Academy of Sciences, Committee on Science and Public Policy, *The Growth of World Population* ... (1963), pp. 14-16; Jain, "State growth rates and their components" (1967), p. 26; Vallin, "La mortalité dans les pays du Tiers Monde ..." (1968).

<sup>379</sup> Balfour, "Some considerations regarding the permanence ..." (1956); Stolnitz, "Comparison between some recent mortality trends ..." (1956); Coale and Hoover, *Population Growth and Economic Development* ... (1958), pp. 14-15; Dorn, "Mortality" (1959), p. 457; United Nations, *Some Issues of Development Policy* ... (1969), p. 7.

<sup>380</sup> Davis, "The population specter ..." (1956); "The unpredicted pattern of population change" (1956), pp. 56-57,

countries of the region, but very slowly in the economically backward countries. After 1930, however, there were extremely rapid gains in life expectancy in which all countries of the region shared nearly equally, regardless of the level or rate of their economic development.<sup>381</sup>

199. A number of studies have emphasized the role of disease control, sanitation measures and medical care in recent mortality decline in developing countries. Impressive recent reductions in infant and childhood mortality in Latin America have been linked *inter alia* to expansion in the provision of pre-natal care for mothers and post-natal care for infants, to campaigns against diphtheria, whooping cough and malaria, as well as to progress in extending the coverage of safe water supplies in both urban and rural areas.<sup>382</sup> The provision of a safe water supply for over ninety per cent of the population and a relatively satisfactory ratio of physicians to population numbers have been mentioned as factors in the striking rise of life expectancy in Trinidad and Tobago between 1920 and 1960.<sup>383</sup>

200. Most students of African population believe that death rates on that continent are falling, though there are few precise data to document such a trend. Mass campaigns against specific diseases and extension of health services are generally credited with much of the achievement thus far,<sup>384</sup> though the decreasing incidence of famines resulting from better agricultural methods and improved transport and storage facilities, and the better nutrition resulting from rising levels of living, have also been mentioned.<sup>385</sup> A sharp fall in the death rate in the United Arab Republic between 1945 and 1947 has been attributed mainly to the nation-wide DDT dusting programme, which was directed against typhus, but may have been effective in destroying vectors of other diseases as well. The introduction and increasing use of antibiotics, such as sulfa compounds and penicillin, are believed to have significantly curtailed mortality from

pneumonia, other respiratory diseases, typhoid fever and a large group of enteric diseases.<sup>386</sup>

201. A malaria control programme and vaccination against whooping cough were considered to be important causes of a decline of more than fifty per cent in death rates in certain rural areas of New Guinea between 1949 and 1965.<sup>387</sup> In Madras City, where the infant mortality rate declined from 165 in 1951 to 115 in 1962, this trend was attributed to various factors such as compulsory vaccination, the Malaria Eradication Programme which also increased the population's resistance to other diseases, the training of midwives, the provision of basic pre-natal and post-natal services to mothers and infants in maternity clinics, and the increasing frequency with which confinements take place in hospitals.<sup>388</sup> Effects of the introduction of safe water supplies in Asian countries are illustrated by the sharp reductions in the incidence of communicable diseases which occurred in Japan, and in deaths due to cholera, typhoid fever and diarrhoeal diseases in Uttar Pradesh, India.<sup>389</sup>

202. In contrast to the emphasis placed on public health and disease control measures by most of the authors cited above, Taylor and Hall believe that the principal forces accounting for recent mortality declines in developing countries have been general economic and nutritional improvement. They cite such factors as improved agricultural methods resulting in more and better food, better transportation resulting in a reduction of food losses, decreased crowding in housing and improved water supply, which reduce the spread of communicable diseases, and better basic education which increases understanding of personal hygiene.<sup>390</sup> Like Taylor and Hall, Frederiksen has credited economic development with having been the major influence in recent gains in life expectancy. In analysing data for Ceylon, Guyana and Mauritius, he found a close correspondence between trends in the death rate and in economic conditions.<sup>391</sup>

203. Various other writers have also cited general improvements in economic conditions and the standard of living as having played a role in recent mortality declines, though few have gone as far as Taylor and

<sup>381</sup> Arriaga and Davis, "The pattern of mortality change in Latin America" (1969).

<sup>382</sup> Johnson, "Public health activities as factors in levels and trends of mortality and morbidity in developing countries" (1966), p. 327. A considerable fall in Brazil's death rate is said to have been due to the application of modern medical knowledge and improved sanitation measures. Smith, *Brazil* . . . (1963), p. 110.

<sup>383</sup> Das Gupta, "Mortality patterns in developing countries" (1970). The author also cited the existence of fairly satisfactory housing conditions and a higher standard of living than is found in many developing countries, as factors favourable to mortality decline in Trinidad.

<sup>384</sup> Caldwell, "Introduction" (1968), p. 11; Coale, "Estimates of fertility and mortality in tropical Africa" (1968), p. 185; Caldwell, "Population policy: a survey of Commonwealth Africa" (1968), p. 370. Campaigns against malaria, yellow fever, smallpox and bilharzia are believed to have been effective, mainly in urban areas. Johnson, "Health conditions in urban and rural areas of developing countries" (1964), p. 302. It is thought that the relatively low mortality in Ghana, in comparison with the rest of tropical Africa, is related to the accessibility of modern health services in the southern part of the country, where 80 per cent of the population resides. Caldwell, *Population Growth and Family Change in Africa* (1968), pp. 10-11.

<sup>388</sup> Chandrasekhar, "Infant mortality in Madras City" (1967), p. 102. A fairly rapid decline in the neonatal mortality rate among the Maoris in New Zealand was found to be associated with a sharp rise in the proportion of confinements occurring in hospitals. Pool, "The isolation of various components . . ." (1967), p. 511.

<sup>389</sup> Dieterich and Henderson, *Urban Water Supply Conditions and Needs* . . . (1963), p. 20. On the range of diseases affected by improvements in community sanitation, see Swaroop, "On infant and childhood mortality . . ." (1955), p. 559.

<sup>390</sup> Taylor and Hall, "Health, population and economic development" (1967).

<sup>391</sup> Frederiksen, "Determinants and consequences of mortality and fertility trends" (1966), pp. 716-717. In another study of twenty-one countries, most of them industrialized, the same author found a high negative correlation between trends in economic indicators and age-specific mortality rates, particularly in the younger age groups. See his "Dynamic equilibrium of economic and demographic transition" (1966).

Hall and Frederiksen in evaluating their importance. Robinson's analysis of the factors contributing to the acceleration of mortality decline in Pakistan after 1950 led him to conclude that this trend was due to "... an interrelated complex of socio-economic and medico-environmental causes; that increases in *per capita* income and the more general availability of modern drugs on the market may have been at least as important as disease-specific health programmes by government."<sup>392</sup> Janer has suggested that the rise in life expectancy in Puerto Rico from 38 years in 1920 to 46 years in 1940 was mainly the result of public health and sanitation measures adopted by the Government, while a further rapid rise to 61 years by 1950 reflected profound social and economic improvements as well as intensified health and sanitation efforts, which, *inter alia*, eliminated malaria as a cause of death and brought a safe water supply to the entire population.<sup>393</sup>

204. The reasons for the remarkable post-war mortality decline in Ceylon—often cited as an example of the results which public health measures alone can achieve—have been examined by various authors, who reached differing conclusions. Nearly all analyses have credited the malaria eradication programme, which introduced DDT spraying to destroy the malaria-carrying mosquito, with having played a leading role in bringing down the death rate from an average of about 21 per 1,000 population in 1936-1945 to about 12 in 1950-1952.<sup>394</sup> Coale and Hoover estimated that the DDT campaign accounted for somewhat less than half of this decline, and Newman's analysis implied that about 42 per cent of the fall in average crude death rates from 1930-1945 to 1946-1960 was due to that cause.<sup>395</sup> On the other hand, Frederiksen questioned the finding that malaria control was a major cause of post-war mortality decline. His studies found that the per cent decline in the death rate between 1946 and 1947 was about the same in malarious and non-malarious areas and was associated with a rise in food imports and improvement in a range of economic indicators.<sup>396</sup> Meegama also stressed the contribution of factors not directly associated with malaria control. He showed that some improvements in mortality had been achieved prior to the advent of DDT spraying, even in endemic malarial areas in which efforts had been made to develop health services. Moreover, like Frederiksen, he noted that declines in mortality occurred in 1947 in certain non-malarious areas in which there had been no eradication campaign and little new hospital construction, apparently as a result of improvements in food supplies following the severe shortages of the war period. Comparing the

situation in Ceylon and Guatemala, Meegama concluded that although both countries had post-war malaria eradication programmes, the much more rapid fall of mortality in Ceylon was due to the existence of rural hospitals and maternity homes, para-medical services and distribution of free milk, whereas these favourable conditions were either absent or were much less developed in Guatemala.<sup>397</sup> In Mauritius, where post-war mortality trends closely paralleled those in Ceylon, Dowling ascribed the fall in the death rate in part to malaria control, but also to improvements in environmental sanitation and prosperity in the sugar industry.<sup>398</sup>

205. The view has been expressed that while public health programmes for the control of disease and progress in environmental sanitation have been extremely successful in bringing about rapid short-term declines in mortality, social and economic factors might assume greater importance in achieving long-run effects.<sup>399</sup> Moreover, at least a slowly rising level of living would seem essential in order for the developing countries to achieve and maintain the low mortality levels now prevailing in advanced industrialized countries.<sup>400</sup> The latter thesis gains support from the research of Behm and Gutierrez, who examined mortality trends in Chile from 1937 to 1963. They found a sharp acceleration in the decline in mortality from infectious diseases in 1945 and 1950, coinciding with the introduction of antibiotics, sulfas and other modern drugs. However, by the early 1960s death rates had stabilized, although at a level still well above that prevailing, for example, in England and Wales. According to the authors, these trends suggest that there is a limit to the mortality decline that can be achieved primarily through medical techniques, if economic development remains at a low level.<sup>401</sup> Similarly, Sarkar, in analysing

<sup>397</sup> Meegama, "Malaria eradication and its effect on mortality levels" (1967). Stolnitz also recognized the contribution of factors other than the malaria eradication programme, notably other health activities and the rapid recovery of food supplies. Stolnitz, "Comparison between some recent mortality trends ..." (1956), pp. 27-29. See also Sarkar, *The Demography of Ceylon* (1957), pp. 124-125; Pampana, "Effect of malaria control on birth and death rates" (1955), pp. 498-500; Newman, "Malaria eradication and its effect on mortality levels ..." (1969); Meegama, "The decline in maternal and infant mortality and its relation to malaria eradication" (1969); Newman, "Rejoinder" (1969); Meegama, "A reply" (1969); and Frederiksen, "Malaria eradication and the fall of mortality ..." (1970).

<sup>400</sup> Vallin, "La mortalité dans les pays du Tiers Monde ..." (1968), pp. 859-861; Thompson and Lewis, *Population Problems* (1965), p. 441. It has been said that in those Asian countries where crude death rates have already fallen below 10 per 1,000, further reductions are likely to be increasingly dependent on improvements in economic and social conditions. United Nations Economic Commission for Asia and the Far East, *Report of the Asian Population Conference, 1963 ...* (1964), p. 80.

<sup>401</sup> Behm and Gutierrez, "Structure of causes of death and level of mortality: an experience in Latin America" (1967). Commenting on the rather small gain in life expectancy in Chile between 1952 and 1960 (0.2 years annually for males and 0.4 years for females) despite the rather advanced state of public health services, Miró

<sup>392</sup> Robinson, "Recent mortality trends in Pakistan" (1967), p. 38.

<sup>393</sup> Janer, "Medidas de salud pública y saneamiento ..." (1955).

<sup>394</sup> See, for example, Cullumbine, "An analysis of the vital ..." (1950); Stolnitz, "Comparison between some recent mortality trends ..." (1956), p. 29; Abhayaratne and Jayewardene, *Fertility Trends in Ceylon* (1967), p. 22.

<sup>395</sup> Coale and Hoover, *Population Growth and Economic Development ...* (1958), pp. 66-67; Newman, *Malaria Eradication and Population Growth* (1965), pp. 48-49.

<sup>396</sup> Frederiksen, "Malaria control and population pressure in Ceylon" (1960); ———, "Determinants and consequences of mortality trends in Ceylon" (1961).

post-war mortality trends in Ceylon, speculated that while methods external to the community had been applied effectively to achieve rapid mortality decline in a short period, future progress would depend more on rising income and general economic and social development.<sup>402</sup>

206. In examining the factors responsible for the existing differences in mortality levels among sixty-three developing countries, Kusakawa tentatively concluded that "... the combined effect of urbanization, literacy, energy consumption, non-agricultural activities and income in that order, may account for one-half or even more of the variations in  $\%_0$  in developing countries, while a little less than one-third of the variation may be attributable to health services alone." The author considered that while specific medical and public health measures were the main factors in the sharp post-war fall of death rates in developing countries, favourable economic conditions were important in permitting the realization of maximum benefits from health programmes.<sup>403</sup>

207. As pointed out in the earlier discussion of the determinants of mortality trends in industrialized countries, owing to the complicated interrelationships of factors, it is difficult to isolate the influences of particular medical advances, public health measures or economic and social conditions. If more were known of this complex subject, Governments of developing countries could benefit by making the most advantageous allocation of available resources.<sup>404</sup>

## 2. FACTORS IN THE PERSISTENCE OF HIGH MORTALITY IN CERTAIN REGIONS

208. Despite the remarkable advances in extending life expectancy which have been achieved in the world's developing regions—mainly in the 1950s and 1960s—mortality levels remain high in large parts of Asia and in most of Africa, compared with conditions prevailing in the more developed regions. The former areas are still beset by infectious diseases not yet brought fully under control (see section D above), unsatisfactory sanitation conditions, food shortages and malnutrition, all of which contribute to their excess mortality.<sup>405</sup> In addition to insufficient quantities of food, diet deficiencies in many of the less-developed regions produce nutritional disorders such as kwashiorkor (resulting from protein deficiency),

concluded that further progress might depend on a general rise in the standard of living. Miró, "The population of Latin America" (1964), p. 40.

<sup>402</sup> Sarkar, *The Demography of Ceylon* (1957), pp. 275-276. Davis has also pointed out that while it is possible to lower death rates substantially through modern techniques, unless there is accompanying social change (for example, an improved understanding of health among the population), the gains achieved may be in jeopardy. Davis, *The Population of India and Pakistan* (1951), pp. 51-52.

<sup>403</sup> Kusakawa, "Social and economic factors in mortality in developing countries" (1967).

<sup>404</sup> Benjamin, "Mortality trends in the world" (1966), p. 219. See also World Health Organization, *Programmes of Analysis of Mortality Trends and Levels* ... (1970), p. 12.

<sup>405</sup> Swaroop, "On infant and childhood mortality ..." (1955), pp. 558-559.

rickets, scurvy, beriberi and pellagra—all of which are now virtually unknown in the industrialized countries.<sup>406</sup> The fact that the mortality rate from certain infectious diseases such as measles and whooping cough is many times as great among children in the developing countries as in Western Europe is believed to be associated with the relatively poor nutritional state of the population in the former areas.<sup>407</sup>

209. The provision of safe water supplies can contribute much to eliminating severe water-borne diseases such as cholera and typhoid, as well as to reducing the incidence of dysentery and gastro-enteritis which are sometimes transmitted by water. But, in the 1960s it was estimated that only about one-third of the urban population in developing countries had drinking water supplies in their houses or on their premises, while a much worse situation prevailed in the rural areas. Moreover, the present rate of progress in increasing water supplies in the urban communities of many developing countries is not sufficient to keep pace with rapid population growth.<sup>408</sup> So far as medical services are concerned, the target ratio of one doctor for every 10,000 inhabitants in developing countries set for the United Nations Development Decade is far from achievement in many parts of the world.<sup>409</sup>

210. At the Asian Population Conference in 1963 it was considered that the wide differences then existing in mortality levels among countries in the region as a result of unequal progress in reducing death rates would disappear with the application of modern medical knowledge and further development of public health activities in the more backward areas. Both India and Pakistan, for example, still have far to go in controlling such diseases as malaria, typhoid, tuberculosis and cholera.<sup>410</sup>

211. Even where mass disease control campaigns have achieved outstanding success, it has proved difficult to establish sufficient complementary health services for the population in view of its rapid growth and the huge costs involved. A considerable lag in providing services for the rural population is evident, partly because of the reluctance of personnel to serve in remote areas under poor conditions. Poor urban environmental conditions accompanying rapid urbanization, and the fact that Asia is the least adequately fed region in the world, further complicate health problems.<sup>411</sup>

<sup>406</sup> Benjamin, *Social and Economic Factors Affecting Mortality* (1965), pp. 21-23; Brockington, *World Health* (1958), pp. 31-32.

<sup>410</sup> United Nations, Economic Commission for Asia and the Far East, *Report of the Asian Population Conference, 1963* ... (1964), pp. 5, 80; Robinson, "Recent mortality trends in Pakistan" (1967), p. 34. According to the author, by the late 1960s the malaria eradication programme was estimated to have reached about 40 per cent of the population in Pakistan.

<sup>411</sup> United Nations, "Recent social trends and developments in Asia" (1968), pp. 55-56. Although health experts have pointed out that the provision of pure water supply and sanitary means of waste disposal would be more effective than any other measure to promote

(Continued on next page)

212. In the Philippines it was estimated that in the late 1960s less than half the population was provided with safe water supply and an adequate waste disposal system. Pneumonia was still the leading cause of death. Its high incidence probably was related to a high frequency of malnutrition among young children, failure to seek early medical attention—particularly in rural areas which suffer most from inadequate medical facilities—and the inability of many to afford the “wonder drugs” which greatly reduce mortality from this disease.<sup>412</sup>

213. In addition to nutritional deficiencies and poor housing conditions, both of which result from low income, various social and cultural factors are believed to contribute to the high infant mortality levels still prevailing in India. The latter are said to include various unhealthy customs surrounding confinement and the feeding of young infants, the preference of Indian women for their babies to be delivered at home even when hospital facilities are available, the traditional role of the untrained midwife, and generally poor “mothercraft”.<sup>413</sup>

214. Malaria eradication remains a primary problem in Africa, where the great majority of the population living in malarious areas is not yet protected against this disease.<sup>414</sup> In addition to the infectious diseases still prevalent in Africa, insufficient food and poorly balanced diets are also factors making for high mortality. In 1949 a WHO-FAO committee linked kwashiorkor to high mortality rates in some parts of Africa,<sup>415</sup> but medical surveys in Gambia in the 1950s, the results of which were believed to be typical also of conditions elsewhere in rural West Africa, found kwashiorkor to be rare, and infection and poor care, rather than malnutrition, to be the main causes of high mortality. It was considered likely that the incidence of gastro-intestinal infections would remain high in tropical Africa until effective vaccines were produced.<sup>416</sup> In a study of infant mortality in rural Tanganyika, high mortality rates were found to

be associated with unhygienic practices at childbirth, insanitary home conditions, and unhygienic feeding.<sup>417</sup>

215. The shortage of trained medical personnel in Africa is shown by the high ratio of inhabitants per physician; while this ratio varies widely among African countries, the regional mode was estimated to be about 21,000.<sup>418</sup> The inadequacy of such a ratio is apparent by comparison with the situation in developed countries; for example, in the Soviet Union the number of inhabitants per physician was only about 500 in the early 1960s.<sup>419</sup>

216. Despite the fact that Latin America has progressed further than the world's other developing regions in bringing mortality to a low level, health conditions in that region cannot be considered satisfactory. The still high incidence of preventable infectious diseases as causes of death has already been mentioned.<sup>420</sup> It has been conjectured that Brazil's death rate, estimated at around 20 in 1950, was double what it would have been if modern medicine and sanitation measures were applied to the same extent as in developed countries. Climate, poor dietary habits and the absence of a strong health tradition, are said to be among the factors holding back more rapid progress in combating disease.<sup>421</sup>

217. For the region as a whole it was suggested in the late 1960s that previously rapid downward trends in mortality may have slowed, since the mass disease eradication efforts had already had their maximum impact, and nutritional and environmental inadequacies were imposing limitations on the results of present public health work. Diseases spread by polluted water were said to be the leading causes of death in many Latin American countries and while provision of safe water supply and sanitation systems are costly undertakings, ambitious improvement programmes were underway, with an impressive proportion of external financing.<sup>422</sup> As of 1964, it was estimated that close to 70 per cent of the urban population of Latin America lived in homes with piped water, though for rural population the figure was less than four per cent. A little over half of the urban population was served by sewerage systems. Goals for 1971 established in the 1961 Charter of Punta del Este called for the provision of safe water supplies and sewerage facilities to 70 per cent of the urban population and 50 per cent of the rural population in each country.<sup>423</sup>

218. One of the major preliminary findings of the Inter-American Investigation of Mortality in Childhood is the role of nutritional deficiencies as contributory causes of death. While nutritional deficiency was the underlying

(Footnote 411 continued)

public health in Asia, there has been no breakthrough in these areas because of the costs involved. United Nations, “Review of the social situation in the ECAFE region” (1965), p. 41. Calorie consumption in the Far East around 1960 was calculated to be only about 89 per cent of requirements, this being the lowest figure for any major region. cause of death in only 10 per cent of the cases among children six months to four years of age, it was a contributory cause in 31 per cent, and a consequence of the underlying cause in 15 per cent of the cases.<sup>424</sup> The fact that infant mortality in Antigua was 2.8 times that in England and Wales around 1960 and nearly sixteen times higher at age one is said to be partly due to relatively poor environmental hygiene, poor diet and malnutrition in the former island.<sup>425</sup>

## I. Prospects for future trends

219. The prolongation of human life is universally viewed as a positive goal, providing an ever-present incentive for direct efforts in the areas of medicine and public health. At the same time, economic and social progress can be expected to exert a favourable, though indirect, effect on mortality. Thus, barring catastrophic and completely unpredictable events such as thermonuclear warfare, unusually severe famines, the recrudescence of great killer diseases or the appearance of new ones, life expectancy is likely to continue its upward trend in both developed and developing countries, although at a varying pace. In the future as in the recent past, the most rapid rates of mortality decline will no doubt occur in the world's developing countries, with the result that, given the younger age structure of their populations, crude death rates in certain regions such as Latin America can be expected soon to fall below those in the more developed regions.

### 1. PROSPECTS IN AREAS OF RELATIVELY HIGH MORTALITY

220. Despite the striking declines in mortality which have occurred in many developing countries since the end of the Second World War, the endemicity of infectious and parasitic diseases throughout large portions of the developing world leaves much room for improvement. The great strides recently recorded have often been made in the absence of significant economic development by the application of procedures borrowed from the industrialized countries and by crash programmes aimed at the eradication of a specific disease, such as the oft-cited anti-malaria campaign in Ceylon. Progress along these lines is expected to continue, with the help of foreign Governments as well as private and international organizations (particularly the World Health Organization).

221. A recent evaluation by the United Nations of the course of mortality trends in developing regions considers an average gain in life expectancy of eight and a half years (from 49.5 to 58.0 years) as likely for 1965-1985, with the rate of improvement varying from region to region.<sup>426</sup>

<sup>424</sup> Puffer and Serrano, "Inter-American investigation of childhood mortality" (1969), pp. 16-17. It was found that two-thirds of the young children who died from measles in Recife, Brazil had a pre-existing nutritional deficiency. *Ibid.*, p. 17. Even in Trinidad and Tobago, where mortality has fallen to quite low levels, a recent nutrition survey revealed severe protein deficiencies among children. Das Gupta, "Mortality patterns in developing countries" (1970).

<sup>425</sup> Uttley, "Age-specific death rates ..." (1965), p. 102.

<sup>426</sup> United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

While the short-run outlook therefore appears to be good, various writers consider that once certain threshold levels are attained, progress will become more difficult. Stolnitz, for example, presents the broad hypothesis that a life expectancy of at least 50 to 55 years can be readily attained where Governments are willing to set such goals, but that improvements beyond these limits will meet with increasing difficulty.<sup>427</sup> According to Vallin, an expectation of life of 60 to 65 years might be achieved in low-income countries without substantial economic progress, but beyond this point increases will be closely related to economic development. Thus, in the absence of sizable economic growth, life expectancy in developing countries may remain on a plateau below the levels now prevailing in the West.<sup>428</sup> An insufficiency of the food supply may be especially important in keeping the potential for mortality reduction from being fully realized.<sup>429</sup>

### 2. PROSPECTS IN AREAS OF RELATIVELY LOW MORTALITY

222. Since the life span in the developed countries is already within sight of man's natural biological limits as they are at present empirically established, further marked extensions are not generally foreseen for these areas in the short run. The same United Nations study cited above projects an increase in expectation of life at birth in the more developed regions of only about two years (from 70.4 to 72.2 years) in the period 1965-1985.<sup>430</sup> Indeed, it has been pointed out that death rates at the very oldest ages may even increase because mortality from a chronic condition has been postponed by medical treatment to a later age. Moreover, new environmental hazards, in the form of air and water pollution, and the possible contamination of food supplies through the use of pesticides and additives, pose a challenge to efforts to increase life expectancy in the older ages.<sup>431</sup>

223. Despite these obstacles to increased longevity, however, there is room for improvement in mortality from certain causes and among certain age groups, within the limits of present-day science and technology.<sup>432</sup> The relatively wide range of infant mortality rates still prevailing among developed countries, and the mortality differentials between certain sub-groups (whether geographic, socio-economic or ethnic) within these countries give evidence of the potential for further mortality reduc-

<sup>427</sup> Stolnitz, "Recent mortality declines ..." (1967), p. 380.

<sup>428</sup> Vallin, "La mortalité dans les pays du Tiers Monde ..." (1968). Although the development necessary to reach a life expectation of 60-65 years is thought to be relatively modest, not approaching the levels of living characteristic of Western countries, in Vallin's opinion many developing countries would nevertheless experience considerable difficulty in attaining it.

<sup>429</sup> See Gordon and Helmer, "Report on a long-range ..." (1966), p. 58.

<sup>430</sup> United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

<sup>431</sup> Spiegelman, "Mortality in the United States ..." (1968), p. 532. According to Légaré, the conditions of modern life, particularly in large cities, may have increasingly adverse effects on persons reaching the later years of their working life. Légaré, "Mortality at age forty-five and over ..." (1967), p. 417.

<sup>432</sup> McKeown envisages the virtual disappearance of deaths before the end of the reproductive period. See his "The next forty years in public health" (1964), pp. 275-276.

tion. This may be achieved through the increased prevention of difficult-to-cure diseases about whose aetiology there is some knowledge (for example, the influence of smoking on respiratory cancer), through earlier detection of certain diseases as a result of improved diagnostic procedures as well as through frequent examination of various "high-risk" groups (overweight persons, for example), and through a continuance of the declining trend in mortality from accidents in the home or at work as a result of better safety measures.<sup>433</sup> Peller has noted that systematic surveys of mortality from cardiovascular diseases in different areas may disclose important information concerning the possible relation of these diseases to such factors as occupation, diet, smoking and drinking habits, ethnic characteristics, altitude or atmospheric conditions.<sup>434</sup> Optimistic assessments have been made of

<sup>433</sup> The outlook for an early reduction in mortality from motor vehicle accidents, which have recently taken an increasing toll in industrialized countries, is less optimistic.

<sup>434</sup> Peller, *Quantitative Research* ... (1967), pp. 298-299.

the prospects for a significant reduction in mortality from heart disease in the near future. Contributing to this progress will be advances in surgery and pharmacology, and possibly most dramatic of all, the development of an artificial heart to replace a diseased one.<sup>435</sup>

224. In contrast to the somewhat modest gains foreseen for the short run is the more speculative, long-range prediction that biological breakthroughs may extend the life span by as much as fifty years before the year 2100. Among the important developments making such an advance possible would be the availability of general immunization against bacterial and viral diseases, and the achievement of chemical control of the aging process.<sup>436</sup>

# POPULATION DISTRIBUTION, INTERNAL MIGRATION AND URBANIZATION

1. As verified by repeated censuses, human populations are very unevenly distributed in space, and the distributions undergo continuous change. The unevenness of population distribution is increasing in modern times as ever larger percentages of human population are becoming concentrated in small parcels of urban land. Unevenness in the distribution of population settlement can result either from migration or from relative differences in rates of natural increase. For example, the higher rates of natural increase in the developing regions are causing a continuous shift of the world population balance in favour of the developing countries. The early growth of industrial cities was primarily due to migration from the countryside. More recently, however, the role of natural increase in the growth of cities has become an increasingly important factor.

2. Throughout the nineteenth century and at the beginning of the present century, overseas migrations, then of large volume in relation to the populations affected, attracted special attention. As shown in chapter VII, these movements have more recently diminished in scale and in the 1950s and 1960s they affected only a reduced number of countries significantly, many of them comparatively small. International movements among countries within the continents of Africa, Europe and Latin America have remained on a considerable scale. But as regards geographic distances and environmental differences between areas of departure and destination, it is important to note that population movements within large countries are of as wide a scope, if not wider, than many movements between neighbouring countries having separate sovereignty. The radius and directions of geographic displacement have changed, but populations have remained as migratory as before. The environmental contrast is now particularly striking between urban and rural areas. With the increasing scale and tempo of urbanization, much of the geographic mobility of populations is now to be attributed to transfers between rural and urban places of residence. At high levels of urbanization, many of the movements are interurban, or between the central parts of cities and their respective suburbs. Since migration is selective of population groups with particular sex, age and marital status characteristics, or with distinct levels of education and occupational qualification, it also causes changes in the compositions of local populations and manpower, according to these features.

3. The study of population distribution, internal migration and urbanization is highly dependent on the definitions of area units, the definitions of a "migratory" move (for instance, in terms of minimal duration of

residence), and the types of data available. Since the statistical systems of countries differ, much of the study is perforce intranational, with results which do not lend themselves readily to international comparison. Even so, the subject-matter is very complex, involving numerous distinct lines of analysis. Exhaustive study for an entire nation can lead to a multiplicity of results not easily summarized for intellectual comprehension. On the other hand, studies relating to particular areas assume the specific geographic circumstances existing in each area. Since these differ from one area to another, they lead to results difficult to compare among different areas, even if the national statistical system is the same. Nevertheless, many attempts have been made, some of them fairly successful, to derive some generalizations from the numerous available observations. In addition, for purposes of international comparison, attempts have been made to estimate and project national urban and rural populations, distinguishing also urban settlements of different size classes.

4. Though population distribution, internal migration, and urbanization are three different topics, they are obviously interdependent and therefore they are reviewed within the same chapter. Population morphologies can be studied in terms of geographic distribution and levels of urbanization. The dynamics by which these structures are continuously changed consist chiefly in the volume and characteristics of migratory streams. Their study is further conditioned by the review of economic, social, demographic and cultural factors apt to influence migratory movements, and by the fact that some Governments have adopted deliberate policies with a view to modifying the migratory currents and hence also the eventual patterns of population distribution.

5. The present chapter is organized in five sections. Section A deals with population distribution among distinct geographic regions, the geographic, cultural and demographic factors affecting it, and their changing influence in modern times. Section B is concerned with the study of internal migration among different geographic regions, the development of data and methods for such study, and a review of the principal migratory currents that have recently been observed. Section C examines the findings on urban and rural population growth as related to recent rises in levels of urbanization and the environmental change resulting from the distribution of population among localities of diverse sizes. Section D reviews theoretical considerations and empirical findings having regard to the motivation of migration, as further conditioned by the economic organization of space, with consequent accumulation of population in localities of

varied size and function. Finally, national policies designed to influence the distributional patterns of population are discussed in section E.

### A. Distribution of world population

6. The population of the earth is distributed unevenly. According to Clarke, only about 30 per cent of the world's land area is permanently inhabited, the precise percentage depending on the minimum density accepted as a limit of substantial habitation. Over 75 per cent of the world's population live in South and East Asia, Europe and the north-eastern part of North America.<sup>1</sup>

7. A common way of describing the world pattern of population distribution is to identify (a) major areas of concentration, (b) minor areas of concentration, and (c) large relatively empty spaces.<sup>2</sup> Fawcett identified four major areas of population concentration, namely, the Far East, India, Europe, and east-central North America.<sup>3</sup> Wheeler, Kostbade and Thoman defined three main clusters: the largest included part of China, Japan, India, Pakistan, Indonesia, and several other countries; the second major cluster comprised Europe and portions of the USSR; and the third cluster consisted of the eastern part of the United States and adjoining parts of Canada.<sup>4</sup> James recognized two major areas of concentration: (a) south-eastern Asia, where roughly one half of the world's population is crowded into less than one tenth of the earth's habitable area, and (b) Europe, where nearly one fifth of the world's population occupies less than one twentieth of the habitable land area.<sup>5</sup> Minor areas of concentration have been exemplified by Java, the population clusters in south-eastern Australia, the Nile floodplain and delta, the Guinea coast of Africa, south-eastern South America, the clusters of Middle America, and those along the Pacific fringe of the United

States and Canada. In strong contrast with the areas of major and minor population concentrations are the large, relatively unoccupied areas of the world. James noted that most of the earth's surface is uninhabited, while vast areas are settled only with small and widely separated communities.<sup>6</sup> The majority of these relatively unpopulated regions is found in the dry lands, the cold lands, in extensive areas of hot and humid lands with intensively leached zonal soils, and in scattered areas of stony and difficult terrain.<sup>7</sup>

8. Within the major and minor areas of concentration and within the sparsely settled regions, there are local agglomerations in metropolitan centres, cities, towns and villages, and rural districts of relatively dense population as well as localities which are sparsely settled or totally uninhabited. The world-wide picture of population distribution is thus exceedingly complex. While characterized by a considerable degree of stability, it is constantly changing in its details and over a period of time changes of considerable importance take place.<sup>8</sup>

9. A commonly used index of the relationship between population and the area in which it lives is the population density ratio, obtained by dividing the population by the area of the territory.<sup>9</sup> Such crude density ratios have the disadvantage of taking no account of variations in the quality of land, arising from differences in climate, topography, mineral wealth, fertility of the soil, and the like; nor do they take any account of differences in urbanization and industrialization.<sup>10</sup>

10. Table VI.1 shows the uneven distribution of world population by regions in 1970. While the average world density was 27 persons per square kilometre, the range among the twenty-three regions shown in the table is from a low of 2 in Australia and New Zealand to 280 in Japan. Densities well below the world average are shown for Africa, northern America and Latin America, while relatively high densities occur in Asia and Europe. The average densities shown for major regions often conceal rather wide variations within the region. Thus, while Latin America as a whole has a low population density,

<sup>1</sup> Clarke, *Population Geography and the Developing Countries* (1971), p. 31. Pearl estimated that nearly one half of the world's population was contained within 5 per cent of the total land area, and that, in contrast, 57 per cent of the earth's land area contained less than 5 per cent of the world's population. Pearl, *The Natural History* ... (1939), pp. 266-277. The results obtained, of course, vary with the size of the land units in terms of which the comparison is made, i.e., whether entire countries, provinces, districts etc. See Duncan, "The measurement of population distribution" (1957), pp. 27-28. For other discussions of population distribution and its changes over time see, for example, Jones and Darkenwald, *Economic Geography* (1954), chap. 2; Thomlinson, *Population Dynamics* ... (1965), chap. 21; George, *Géographie de la population* (1967), chap. 1; McGaugh, *A Geography of Population and Settlement* (1970), chap. 2; Trewartha, Robinson and Hammond, *Elements of Geography* (1967), pp. 528-529.

<sup>2</sup> Trewartha, Robinson and Hammond, *Elements of Geography* (1967), pp. 532-533; Rudolphi, "Die Verteilung der Menschen ..." (1935), pp. 337-338; Baker, "Population, food supply ..." (1928), p. 353; George, *Introduction à l'étude* ... (1951), pp. 21-32; Fawcett, "The changing distribution ..." (1937); Vidal de la Blache, *Principes de géographie* ... (1922), pp. 19-32; Franke, "Die Bevölkerung der Erde ..." (1949-1950), pp. 233-237; Jones and Darkenwald, *Economic Geography* (1954), pp. 8-14; Trewartha, *A Geography of Population* ... (1969), pp. 80-90.

<sup>3</sup> Fawcett, "The numbers and distribution ..." (1947); also Trewartha, Robinson and Hammond, *Elements of Geography* (1967), p. 532.

<sup>4</sup> Wheeler, Kostbade and Thoman, *Regional Geography of the World* ... (1961), p. 14.

<sup>5</sup> James, *A Geography of Man* (1949), p. 5.

<sup>6</sup> *Ibid.*

<sup>7</sup> Wenschow, *Atlas für Höhere* ... (1950), pp. 48-58. According to Wheeler, Kostbade and Thoman, *Regional Geography of the World* ... (1961), pp. 14-15, the empty and sparsely populated areas, covering three fourths of the earth's surface, may be grouped into four categories: (1) arctic and subarctic; (2) deserts and dry grassland; (3) rugged highland; and (4) areas of tropical rain forest and tropical grassland. Of these "negative areas", the tropical forests and grasslands are said to offer the best opportunities for future population settlement. For another discussion of the nearly uninhabited regions see Jones and Darkenwald, *Economic Geography* (1954), p. 9.

<sup>8</sup> Clarke has pointed out that the earlier geographers often considered patterns of population distribution as static phenomena, but while population distributions always show some inertia, "such is the dynamism of populations that demographic processes in progress at the moment are likely to modify substantially present distributions". Clarke, *Population Geography and the Developing Countries* (1971), p. 1.

<sup>9</sup> United Nations, *Multilingual Demographic Dictionary* ... (1958), p. 18.

SOURCE: Compiled from United Nations, *Demographic Yearbook*, 1970 ... (1971), table 1, p. 105.

Note: Because of rounding, totals are not in all cases the exact sum of the parts. Population totals for the world, developing and more developed regions have been adjusted to take into account discrepancies between regional assumptions of immigration and emigration.

the Caribbean area has a high density. Northern Europe has an average density of 49, but Finland has only 14 and Norway only 12. In western Europe, Belgium and the Netherlands, with average densities of more than 300, greatly exceed the regional average.

11. Average population density ratios for countries likewise reveal nothing of the variations which may exist in different parts of the country. Average density in the United Arab Republic is not very high, but the great majority of the population is settled in the Nile Valley. In fact, the density ratio in the settled parts of the country is over 500 persons per square kilometre. The island of Java in Indonesia supports a large population in relation to its land area, mainly by continuous crop cultivation, while most other islands of the archipelago have low

population densities.<sup>11</sup> Within highly industrialized countries, also, there are often great regional variations in the density of settlement. The high urban concentration along the eastern seaboard of the United States extending from Boston to Washington D.C., for example, results in a density index many times the national average.<sup>12</sup>

12. While high population densities are found both in industrialized and developing countries, in the former they generally result from urban concentration, while in

<sup>11</sup> United Nations, *Preliminary Report on the World Social Situation* (1952), p. 5; Jones and Darkenwald, *Economic Geography* (1954), p. 10.

<sup>12</sup> On density within the United States see, for example, Bogue, *The Population of the United States* (1959), pp. 58-62; Smith and Zopf, *Demography: Principles and Methods* (1970), pp. 56-65.

the latter they more often reflect the pressure of rural population on the land. Low average densities are also found both in industrialized and developing countries, and are generally associated with a low percentage of total land area that is cultivated.<sup>13</sup> A more useful index of the relationship of population to land in rural areas is obtained by considering only that part of the land which is actually cultivated.<sup>14</sup> Many of the developing countries of generally low population density have a concentration of rural population on cultivated land that is as great as the rural concentration found in the most densely populated industrialized countries. For example, around 1950, ratios of rural population per square kilometre of cultivated land were 140 in Brazil, 164 in Mexico and 189 in Honduras.<sup>15</sup>

13. The factors which determine the pattern of population distribution and its changes are as complex and varied as the patterns themselves. In studies on this subject, three main classes of factors, excluding accident and inertia,<sup>16</sup> have been emphasized: (a) geographical factors, including climate, landforms, soils, other physical resources and space relationships; (b) economic and social factors, including the attitudes and aims of the people, their economic activities and techniques, and their form of social organization; and (c) demographic factors, including the differing birth and death rates of the various areas and the currents of migration.<sup>17</sup> Findings as to each of these classes of factors are summarized in the relevant sections below. It is generally recognized that these factors interact in a highly complex way and that their influence upon the distribution of population is brought to bear through a slow process of adaptation.<sup>18</sup>

## 1. GEOGRAPHICAL FACTORS

14. There is general agreement that physical conditions such as the nature and degree of fertility of the soil, the contour of the surface, climatic conditions, and spatial relations affect the world pattern of population distribu-

tion.<sup>19</sup> However, there is wide difference of opinion regarding the way in which the physical elements operate in shaping the distribution of population.

15. Such authors as Huntington and Taylor tended to view the physical elements, particularly climate, as direct, controlling determinants.<sup>20</sup> Most modern geographers hold that the influence of physical factors is modified in varying degrees by the forms of socio-economic and political organization. The physical influence is believed to vary in importance; the pattern of population distribution is viewed as a product of the interplay of both geographic and socio-economic and cultural phenomena.<sup>21</sup> The processes through which these factors act upon the distribution of human populations resemble in some respects the ecological principles that govern the spatial distribution of plant and animal life; but man to a greater extent than other species exercises control over his habitat. Within limits, man determines his pattern of population distribution.<sup>22</sup>

16. The complexity and interactions of the physical influences, together with the great gaps in present knowledge, render it difficult to assess the effects of each of the elements individually upon population distribution,<sup>23</sup> yet certain generalizations which have been essayed are worth attention.

### (a) The influence of climate

17. Many writers have believed that climate is the most important factor underlying the marked contrasts in the

<sup>13</sup> McGaugh, for example, noted that climate in combination with vegetation and soils, forms a set of geographical elements which influence human settlement. McGaugh, *A Geography of Population and Settlement* (1970), p. 3.

<sup>20</sup> Huntington, *Civilization and Climate* (1924), particularly chap. 18; Taylor, *Environment and Race* . . . (1927). Huntington believed that temperature greatly influenced the mental activity and physical vigour of a population. See his *Mainsprings of Civilization* (1945), particularly chaps. 14 and 18; Brooks cites Peake's conclusion that climatic change was responsible for the migrations which laid the foundation of the present population distribution in Europe and western Asia. Brooks, *Climate Through the Ages* . . . (1949), p. 12. In contrast with the views of the geographic determinists, a study group of scientists, formed in the United States in the 1950s to examine evidence concerning the effect of tropical climates on development, concluded that while tropicity could not be considered the exclusive crucial factor in underdevelopment, there are nevertheless special difficulties affecting human habitation in tropical environments. This group urged further research to determine what tropical conditions may impose "a prohibitively heavy burden upon successful human habitation". Lee, *Climate and Economic Development* . . . (1957), pp. 173-174. See also Myrdal, *Asian Drama* . . . vol. 1 (1968), pp. 677-681.

<sup>21</sup> Blumenstock and Thornthwaite, "Climate and the world pattern" (1941); Beaujeu-Garnier, *Trois milliards d'hommes* . . . (1965), p. 42. Lösch noted that climate, soil and man had co-operated to produce the concentration of population in the north-eastern part of the United States. Lösch, *The Economics of Location* (1954).

<sup>22</sup> Allee et al., *Principles of Animal Ecology* (1949); Hawley, *Human Ecology* . . . (1950), particularly chap. 6; Zipf, *Human Behavior* . . . (1949), particularly chap. 9; Stewart, "Empirical mathematical rules concerning . . ." (1947); and his "Demographic gravitation . . ." (1948); Frank, "Ecology and demography" (1959), pp. 672-673; Duncan, "Human ecology and population studies" (1959).

<sup>23</sup> George in "Géographie de la population . . ." (1950), pointed out the need for many more correlative studies in this field.

<sup>13</sup> United Nations, *Preliminary Report on the World Social Situation* (1952), pp. 5-6. A low percentage of cultivated land may be due to poor quality of uncultivated lands, to the presence of deserts, mountains, jungles etc.; to land uses other than cultivation, to primitive agricultural methods, to land-ownership systems which keep land out of production, or simply to sparse population. *Ibid.*, p. 6. Andrus cites as one factor contributing to Burma's low density, the low proportion of the country's area consisting of flat, well-watered or easily irrigated land. Andrus, *Burmese Economic Life* (1947), pp. 24-25.

<sup>14</sup> For more detailed discussion of the relationship of agricultural population to cultivated land, see chapter XII.

<sup>15</sup> United Nations, *Preliminary Report on the World Social Situation* (1952), p. 6.

<sup>16</sup> On the roles of accident and inertia see Dechesne, *La localisation* . . . (1945), chap. 8; Toschi, "Localizzazione . . ." (1946).

<sup>17</sup> Jones and Darkenwald identified three types of factors affecting the distribution of population: (a) climate, location and relief of the land's surface; (b) the distribution of natural resources such as minerals, water, soils, native plants and animals; and (c) man's technological achievements. Jones and Darkenwald, *Economic Geography* (1954), pp. 8-9.

<sup>18</sup> See, for example, Trewartha, Robinson and Hammond, *Elements of Geography* (1967), pp. 528-529.

density of population in different parts of the world. The major clusters of population in south and east Asia, in Europe and in east central North America are located mainly in subtropical and middle-latitude climates. The subarctic and polar climates of high latitudes are very thinly populated, as are the arid and semi-arid climates and most tropical climates.<sup>24</sup> The effects of climate on habitability are both direct and indirect. Blumenstock and Thornthwaite have pointed out that the patterns of climate, of vegetation, and of soils in various parts of the world coincide to a remarkable degree because climate is the fundamental force shaping the other two. Though man may vary his pattern of culture to a certain extent, he cannot go beyond the limits set by climate.<sup>25</sup>

#### (i) Atmospheric temperature

18. The cold regions are, as a group, the regions of lowest population density in the world. The high latitudes of the northern hemisphere contain about 10 per cent of the surface of the continents but have only a few thousandths of the world's population.<sup>26</sup> On the other hand, the greatest areas of population concentration are located in the outer low latitudes (0°-30°) and in the middle latitudes (30°-60°).<sup>27</sup> Scientific investigations have indicated that no area of the world is too cold to prevent human life.<sup>28</sup> The cold temperatures of arctic and subarctic lands, however, make unattractive areas for settlement. It has been pointed out that polar cold temperature may increase susceptibility to respiratory disease.<sup>29</sup> Other specific climatic features of these areas, such as the long winter nights, the low intensity of solar radiation, even in summer with nearly continuous

sunshine, and, possibly, magnetic phenomena may also have undesirable influences on man. More important, the productive capacity of the cold regions is greatly reduced by the shortness of the growing season. Baker estimated that 6.4 million square miles of the earth's surface were too cold for cropping.<sup>30</sup>

19. As in the case of low temperatures, the indirect, rather than the direct effects of high temperatures appear to be more significant in shaping population distribution and density. With regard to direct influences, Winslow and Herrington stated with certainty that extremes of heat and cold are harmful and that susceptibility to intestinal diseases is increased by moderately hot climate.<sup>31</sup> Sulzberger and his colleagues indicated that prickly heat may be caused by high temperatures alone.<sup>32</sup> Lee noted that there appeared to be no permanent deleterious effects of tropical climates on healthy persons, although the prevalence of infectious diseases in those climates affected the efficiency of work performance.<sup>33</sup> Little is known regarding the effects of radiation in low latitudes. The fact, however, that large populations have resided for centuries in areas of maximum and highest average temperatures indicates that high temperature alone does not prevent human habitation.<sup>34</sup>

20. When high temperatures are combined with high humidity, however, a considerable body of evidence indicates that the effects on human life and activity may be deleterious.<sup>35</sup> The failure of large numbers of Europeans to move into areas that are hot and humid has been particularly noted, and the suitability of these climates for settlement by people of European origin remains a controversial question.<sup>36</sup>

21. There is less division of opinion concerning the indirect influences of high temperatures. On the one hand, high temperatures are favourable to high density of population in that they (a) promote rapid growth of vegetation, (b) permit the practice of multiple cropping, (c) allow the production of a greater range of crops than is possible in cooler areas, and (d) reduce requirements for clothing and shelter. On the other hand, high temperatures presumably stimulate the rapid propagation of insects,

<sup>24</sup> Thoman, *The Geography of Economic Activity* (1962), p. 95. McGaugh identified four types of climates that favoured high population density. See his *A Geography of Population and Settlement* (1970), pp. 37-38. For other classifications of climates see, for example, Thornthwaite, "An approach toward a rational classification . . ." (1948); Lee, *Climate and Economic Development . . .* (1957), pp. 14-20; Trewartha, *An Introduction to Climate* (1968); Stamp, *Our Developing World* (1960), chap. 3. The latter author noted (pp. 62-63) that while European and American geographers have adopted the criterion of climate for classifying different regions of the world, Russian geographers use the criterion of soil.

<sup>25</sup> Blumenstock and Thornthwaite, "Climate and the world pattern" (1941), p. 98. Pearson noted that the limitations set by climate chiefly account for the fact that half the earth's land area is inhabited by less than one person per square mile. Pearson, *The Growth and Distribution . . .* (1935), p. 25. See also Semple, *Influences of Geographic Environment* (1911), p. 610; Markham, *Climate and the Energy of Nations* (1947), p. 38; Rudolphi, "Die Verteilung der Menschen . . ." (1935), p. 337; Jones and Darkenwald, *Economic Geography* (1954), chap. 2; and McGaugh, *A Geography of Population and Settlement* (1970), pp. 37-49. For a description of the various climatic regions of Africa see Mountjoy and Embleton, *Africa—A New Geographical Survey* (1967), pp. 50-69; on west Africa, see Church, *West Africa . . .* (1966), chap. 3.

<sup>26</sup> Shaw points out that "few people live on at least 12,000,000 square miles of the earth's surface largely because of the influence of low temperatures". Shaw, *World Economic Geography* (1955), p. 536.

<sup>33</sup> Lee, *Climate and Economic Development . . .* (1957), p. 99.

<sup>34</sup> Shaw points out that the climate along the Amazon River has been an important factor which limited settlement, but that the climate conditions there are no worse than those in some more densely populated sections of the Congo basin, where settlement is being stimulated by the discovery and exploitation of uranium, copper and other mineral deposits. Shaw, *World Economic Geography* (1955), pp. 539, 544.

<sup>35</sup> Mills, "Climate as a factor in the health . . ." (1932), pp. 573-592; and his "Climatic effects on growth . . ." (1942), p. 12; Dill, *Life, Heat and Altitude . . .* (1938), chap. 4; Trewartha, Robinson and Hammond, *Elements of Geography* (1967), p. 532.

<sup>36</sup> Price, *White Settlers in the Tropics* (1939), pp. 232-238; Gillman, "White colonization . . ." (1942), p. 590; Stone, "Health in tropical climates" (1941), p. 247; Derruau, *Précis de géographie humaine* (1961), pp. 44-45.

fungi and bacteria and, thus, tend to reduce the habitability of such areas. The lack of a seasonal check on the growth of these organisms has been posited as a prime factor in the incidence of disease in the tropics.<sup>37</sup> Diseases of plants and animals, particularly those spread by the tsetse fly, have discouraged settlement in large parts of Africa by rendering areas unsuitable for grazing.<sup>38</sup>

22. A number of writers have attempted to determine the optimum temperature range for human activity.<sup>39</sup> Little evidence exists to support the thesis that temperature alone has a primary influence on the distribution of agricultural population in the low and middle latitudes, though temperature may conceivably have been of greater significance in earlier times. Hence the concept of an optimum temperature may at one time have been more meaningful than it is now.<sup>40</sup> Whether the variable temperatures of the middle latitudes, sometimes considered as optimal, have been important in stimulating industrial development and hence in permitting large aggregations of population, is debatable. Little doubt exists, however, that technological developments have tended to increase the range of temperature régimes under which man can operate effectively.

## (ii) Precipitation

23. Low rainfall sharply limits the habitability of large areas of the earth's land surface; moreover, the rainfall is often not evenly distributed over the year. Baker has estimated that 15 million square miles of the earth's surface are too arid for crops, and James has noted that desert lands which constitute about 18 per cent of the total land area of the world have only about 4 per cent of the world's population.<sup>41</sup> Low precipitation limits the water supply in general and soil moisture in particular and thus imposes a low limit on animal population. Such conditions are not conducive to the development of agriculture. Consequently the primary requisites for development beyond sparse human occupancy are lacking, since without agriculture, the needs for primary service centres and for commerce and industry are negligible.<sup>42</sup>

<sup>37</sup> May, "Map of the world distribution of cholera" (1951); and his "Map of the world distribution of malaria vectors" (1951); Simmons *et al.*, *Global Epidemiology* . . . , vol. 1 (1944), particularly pp. 471-484.

<sup>38</sup> Nash, *Tsetse Flies* . . . (1948), pp. 1-78; Buxton, *Trypanosomiasis in Eastern Africa, 1947* (1948), pp. 1-44; Hance, *The Geography of Modern Africa* (1964), p. 15; Clarke, *Population Geography and the Developing Countries* (1971), p. 103. Shaw considers the implications of the elimination of the tsetse fly for future human settlement in large areas of Africa previously unpopulated or only sparsely populated. Shaw, *World Economic Geography* (1955), p. 553.

<sup>39</sup> For example, Huntington, *Civilization and Climate* (1924), chap. 10; Markham, *Climate and the Energy of Nations* (1947), p. 29; Derruau, *Précis de géographie humaine* (1961), p. 44.

<sup>40</sup> Markham, *Climate and the Energy of Nations* (1947), pp. 40, 76.

<sup>41</sup> Baker, "Population, food supply . . ." (1928), p. 355; James, *A Geography of Man* (1949), p. 39. Worthington has noted that water is scanty in at least three quarters of sub-Saharan Africa. Worthington, *Science in the Development of Africa* . . . (1958), p. 114.

<sup>42</sup> Semple, *Influences of Geographic Environment* (1911), pp. 483 and 504; Broek, "Climate and future settlement" (1941), pp. 232-233.

Complete absence of population is typical of large expanses of the interiors of deserts. Referring to the Sahara, Gautier noted these interior expanses are without any water resources whatever and are "great voids" from a population point of view.<sup>43</sup> Hance observed certain anomalies, however, since the Sahara and Namib deserts and the steppes of East Africa and the Kalahari were very lightly populated, while other areas with long dry seasons have unexpectedly high densities, e.g. parts of northern Nigeria, the Mossi country of Upper Volta, Senegal and Gambia.<sup>44</sup>

24. Population centres may emerge in regions of low precipitation where water is available. However, low precipitation limits the accumulation and availability of subterranean water supplies and only relatively small oases can be supported by water from subterranean sources. The largest oases, exemplified by the lower Nile and Indus, are located along river valleys with tributary headwaters in humid lands. Oases dependent upon "imported" waters permit bands of very densely peopled land which stand in sharp contrast to the great empty areas which surround them. However, James has pointed out that man, with all his efforts to provide water, has succeeded in making only an almost negligible proportion of the desert permanently habitable.<sup>45</sup> The development of agriculture as well as mining and transportation is hindered by scanty water supply, and hence the settlements of people engaged in these activities in arid lands remain small.<sup>46</sup>

25. Moderate precipitation, highly variable in amount from year to year, is typical of extensive subhumid lands. The variability of the rainfall in such areas makes agriculture risky, and the total low annual rainfall limits agricultural output. James has called these lands "distinctly marginal" areas of settlement.<sup>47</sup>

26. In a few areas, excessive rainfall may discourage human settlement, since high precipitation contributes to the excessive leaching of the soil, to erosion, and to unmanageable forest growth.<sup>48</sup> However, high precipitation is not generally regarded as a direct cause of low population density.

<sup>43</sup> Gautier, *Le Sahara* (1923), pp. 89-95. Discussing the Sahara, Church *et al.* noted: "No part of the desert is completely rainless; indeed, some of the higher ranges in the interior get sufficient rain to support considerable vegetation, and might be termed 'altitudinal oases'." See their *Africa and the Islands* (1967), p. 37. See also Mountjoy and Embleton, *Africa—A New Geographical Survey* (1967), p. 62.

<sup>44</sup> Hance, *The Geography of Modern Africa* (1964), p. 52. He also noted the variations in settlement of rainy tropical areas, parts of the West African belt being densely populated, while low densities were found in the rain forest belt of Cameroon, Gabon, and the two Congos.

<sup>45</sup> James, *A Geography of Man* (1949), p. 25. For an opposite, optimistic view of the possibilities of reclaiming and transforming the Sahara for human habitation see Baker, *Sahara Conquest* (1966), p. 180.

<sup>46</sup> Kitson, "Kuwait's distillation plan . . ." (1951), p. 22.

(b) *The influence of landforms*

27. The regions of difficult terrain, like the cold lands and the dry lands, are conspicuous for their low density of population. Generally, this population is likely to be concentrated in small clusters in areas where the landform is hospitable. Even in such a densely populated, mountainous country as Japan the vast bulk of the population is concentrated on the limited peripheral lowlands.<sup>49</sup> The chief deterrents to the peopling of areas of rugged terrain are: (a) the very limited extent of arable land; (b) the difficulty of maintaining existing arable land; (c) the relatively high cost of constructing, maintaining, and operating agricultural equipment and means of transportation; (d) the isolation that is likely to exist; and (e) the adverse effects of altitude on human activities.<sup>50</sup> High mountains, which generally tend to limit population settlement, are estimated to occupy more than one million square miles of the earth's land surface. Not all mountains, however, are sparsely populated. The highland basin of Bolivia, with an average altitude of more than 10,000 feet, has more population than the eastern lowlands. Similarly, the highland basins in Ecuador and Peru are among the more densely populated parts of those countries. Mountains in high latitudes are known to be unfavourable to settlement, not only because of the terrain, but also owing to the cold temperatures. The Scandinavian mountains, or those of north-east Siberia, are instances of sparsely populated high-latitude mountains.<sup>51</sup>

28. With regard to altitude, George estimated that nine tenths of the people of the world live in areas with an elevation of less than 400 metres.<sup>52</sup> Low-lying plains appear to be the most favourable locations for population settlement. The plains areas of the North American and European middle latitudes, for example, are among the more densely populated areas. Some of the plains of the low latitudes also display high population concentration. The Ganges Valley of India is one of the most densely populated plains areas of the world. Some plateaux (that is, plains at higher altitudes) also tend to encourage population concentration because of their relatively low temperatures.<sup>53</sup> In a study of several countries, Semple found that, except in certain tropical and mining regions, the food supply and the density of population decreased with the increase in altitude above a certain level.<sup>54</sup> Very little is known regarding the physiological effects of decreased diffusion and hence of increased intensity of solar radiation at high altitudes, of decreased air pressure, of increased reception of cosmic rays, or of the wide daily range of temperature, characteristic particularly

of tropical highlands.<sup>55</sup> The comparative advantages of plains areas have resulted in a prolonged and continuous out-migration from the highlands in the more advanced regions of the world, a trend which is apparent even in countries with a high population density.<sup>56</sup>

29. Although the most striking evidence of the influence of landforms is to be observed upon the world pattern of population distribution between mountain-lands and plains, landforms are also likely to play a significant role in the distribution of population on a local scale.<sup>57</sup>

(c) *The influence of soils*

30. The attractiveness of a region to settlers may depend partly upon the quality of the soil.<sup>58</sup> The importance of this factor is difficult to assess because differences in the soils of various regions are closely related to differences in climate, vegetation, and landforms.<sup>59</sup> Nevertheless, in localities of nearly uniform climate, landforms and accessibility, variations in the texture and other characteristics of the soil correspond to great local variations in land use and population density. Also, when the earth is considered as a whole, certain broad regions or zones of contrasting soil qualities become evident,<sup>60</sup> and these are related to both the opportunities for settlement and the existing pattern of population distribution. Wolfanger observed that podzolic and lateritic soils—the characteristics of which generally impede intensive cultivation—unfortunately occur in broad belts across the widest dimensions of several continents. The improvement of these soils involves scientific and economic problems of the first order.<sup>61</sup>

31. Most students of soils are agreed that the mature lateritic tropical soils are not suitable for intensive, continuous cultivation of annual crops or even for tree crops and that the possibilities for settlement are limited in those areas where they occur. Such soils require fertilization soon, if not immediately, after the land is cleared, and some experts have noted that they cannot withstand continuous cropping even with the most careful attention.<sup>62</sup> Parsons concluded thus: "Shifting-field

agriculture (migratory agriculture) can be defended in most instances as the best, perhaps the only, means by which permanent production of annuals can be maintained on the mature lateritic soils of the tropics.”<sup>63</sup> Characteristically, this kind of agriculture, which is widely practised in tropical Africa, is accompanied by sparse population settlement.

32. Fortunately not all soils of the humid tropics are of the mature type. Some areas possess soils developed from volcanic products which are better drained and better supplied with plant nutrients. In other tropical areas soils consisting of deep layers of alluvium deposited in recent times are present with superior tilth and nutrient value. Dense populations occupying these areas of exceptional soils stand in sharp contrast to the thin and scattered populations which inhabit the areas of mature lateritic soils. Rudolphi observed that the areas of the densest settlement in south-east Asia are typically found on the unusually large floodplains, piedmont alluvial plains, and other special soil areas.<sup>64</sup> Alluvial soils are said to support a larger proportion of the world's population than any of the main categories of soil.<sup>65</sup>

33. In the higher middle latitudes the podzol soils girdle the earth and coincide approximately with a belt of coniferous forests. These soils yield annual crops only if lime and fertilizer and, especially, phosphorous are applied.<sup>66</sup> Under careful management podzol soils lend themselves to slow improvement. However, on the balance, these soils, together with the climate, have had the effect of discouraging settlement. Their importance in this connexion is suggested by the contrast between the experience of settlement in the clay belt of Canada and in the neighbouring areas of podzolic soils. In the clay belt, the texture and depth of the soil are somewhat superior to the average, and substantial clusters of population have developed here, whereas agricultural settlement in surrounding areas is almost non-existent.<sup>67</sup>

34. The soils of the world's grassland, particularly in the middle and subtropical latitudes, and those of the broadleaf forests in the middle latitudes generally favour relatively dense settlement. According to Kellogg, “the soils developed under grasses are the most productive for the ordinary crop plants under common systems of farming”.<sup>68</sup> In subhumid and semi-arid grassland regions, vast acreages of high-quality soils and favourable topography exist, but the lack of moisture limits them to a low average productivity over long periods of years. The

soils of middle-latitude areas formerly in broadleaf forests are readily adapted to a wide range of grain and forage plants and thus add to the attractiveness of these areas for human settlement.

#### (d) *The influence of energy and mineral resources*

35. The industrialization and mechanization of the world economy have increased the importance of the location of certain minerals as a factor influencing the distribution of population.<sup>69</sup> The power of a mineral deposit to attract population depends on a number of circumstances, including: (a) the importance of the mineral as a raw material or source of energy for various types of production, and the feasibility of substituting other materials or energy sources; (b) the availability of the mineral at other places, the conditions affecting the cost of its production and efficiency of its utilization at each site and the attractiveness of each site from other points of view as a place of habitation;<sup>70</sup> and (c) the cost of transporting the ore or the mineral in various stages of processing to other places where it may be converted into energy or used as industrial raw material.<sup>71</sup> Those minerals which are of fundamental importance as sources of power, or as materials for a wide range of industrial activities and which are difficult to transport and are found only in a few places under favourable conditions, will have the greatest potential to attract population.<sup>72</sup>

<sup>69</sup> Prior to the industrial revolution, the quality of soils was the chief factor influencing population distribution in Europe. See Pounds and Roome, “Population density in fifteenth century . . .” (1971). For a discussion of the effects of the industrial revolution on population distribution in Europe, see George, *Population et peuplement* (1969), pp. 87-99. Dobby discussed the effect on population distribution in south-east Asia of the discovery of deposits of tin in Malaya and nearby islands, and of petroleum in Sumatra and Borneo. See his *Southeast Asia* (1966), p. 389. In Africa, major developments in the mineral industry, particularly since 1939, have influenced the distribution of population. Mountjoy and Embleton, *Africa—A New Geographical Survey* (1967), p. 149.

<sup>70</sup> In this connexion, it is relevant to consider three classes into which all raw materials and factors of production may be divided: (a) those which, being available everywhere under the same conditions, are place-free; (b) those which, being available under the same conditions only at certain places or under various conditions at all places, are conditionally place-bound; and (c) those which, being present only at one site, are unconditionally place-bound. Except in so far as the place-boundness of raw materials and factors of production can be economically overcome by transportation or other means, the distribution of economic activities tends to be dominated by the location of the more or less place-bound factors and materials. Labour, which is one of the factors of production, is to a considerable extent place-bound; therefore, the distribution of economic activities is partly controlled by demographic factors. The classification into the three categories stated above and its importance in the analysis of the determinants of distribution of economic activities are founded on the theory of substitution of commodities and factors of production. See Isard, “The general theory of location . . .” (1949). Isard indicates that Predöhl was the first writer to systematically apply the substitution principle to location theory. See Predöhl, “Das Standortsproblem . . .” (1925).

<sup>71</sup> For a discussion of the importance of transportation for mineral exploitation in Africa, see Mountjoy and Embleton, *Africa—A New Geographical Survey* (1967), p. 150.

36. In the case of coal, and to a lesser extent of iron ore, there is a strong attraction of industry and hence of population at the source of the material.<sup>73</sup> The unique position of coal among mineral raw materials as a magnet for industry stems from (a) the tremendous bulk of coal consumed, (b) its relatively low value per unit weight, (c) the use of coal as a reducer of metals, particularly in the iron and steel industry, and (d) the fact that coal is largely dissipated when used. The importance of the iron and steel industry, together with the high consumption of coal in a host of secondary and tertiary industries, enhances the attractiveness of coal-producing areas to industry and population.<sup>74</sup> Although certain trends indicate that coal may become somewhat less significant in the future,<sup>75</sup> the present distribution of industry in such countries as Australia, France, the Federal Republic of Germany, Poland, the Union of Soviet Socialist Republics, the United Kingdom and the United States reveals the prime importance, at present, of the availability of coal as a base for industrialization.<sup>76</sup>

37. Petroleum and natural gas have been relatively unimportant as attractors of industry.<sup>77</sup> This fact is explained chiefly by the ease of transporting them, by the nature of their uses (particularly in transportation and domestic consumption), and by the unattractive location of many of the producing fields. There has been, however, a considerable movement of plants, particularly in the petrochemical industries and those requiring large and cheap supplies of fuel, to certain producing regions such as the western Gulf area of the United States.<sup>78</sup>

38. Among the non-energy minerals, iron ore in some cases exerts an influence similar to that of coal; in other places it is, as are other non-energy minerals, a relatively weak attractor of industry. Cities and towns have grown up near the sources of these minerals but, with the possible exception of the Rand in South Africa<sup>79</sup> and of

certain iron-ore centres such as the Lorraine or Magnitogorsk, none of them is more than a centre of mining or primary industry. The explanations for the sharp contrast between coal and the other minerals include the following facts: (a) some minerals, including most of the ferroalloys, are mined and consumed in very small quantities; (b) some ores, such as copper, which are mined in large tonnages, can be concentrated close to the mine and the product, being of high value in relation to its bulk, can be shipped readily; (c) some ores have a high value per unit of weight and can be transported economically over relatively long distances; (d) some, such as the non-metallic minerals, are so widely distributed that, even though used in bulk, they exercise only a minor influence upon the location of industry or population; (e) some mineral deposits are exhausted at a relatively rapid rate; and (f) in some cases, the mineral occurs in economically and physically unattractive surroundings so that only a mining and primary processing population is attracted.<sup>80</sup>

39. Sources of energy other than minerals, notably water-power sites, also attract population. The importance of water-power sites, however, is much less than that of the basic minerals, for water power is a relatively minor source of energy.<sup>81</sup> Even if the total potential water power in industrialized nations were fully developed, it could not assume prime importance as an attractor of industry. The possibility of transmitting electricity over great distances reduces its significance in this connexion.<sup>82</sup> Nevertheless, the availability of water power on the Alpine slopes has been cited as a partial explanation of the presence of some 4 million industrial workers in northern Italy and another million in Switzerland. These concentrations are considerable, though much less important than the immense industrial population of the coal producing belt which stretches across Europe from the British Isles to Silesia.<sup>83</sup>

40. It has been pointed out that past experience gives no sure basis for predictions regarding the influence which a mineral deposit or non-mineral source of energy may bring to bear upon the distribution of population. The presence of iron ore in Europe, especially in France, has had a "demographic value", but in the United States and the USSR, similar deposits have attracted no similar concentrations of population. The utilization of pitchblende has not thus far created population centres, but may do so in the future.<sup>84</sup>

<sup>73</sup> See, for example, Ackerman, "Population and natural resources" (1959), p. 623; Lösch, *The Economics of Location* (1954), pp. 83, 90; Trewartha, Robinson and Hammond, *Elements of Geography* (1967), p. 537.

<sup>74</sup> See, for example, the discussion in Isard, *Location and Space Economy* . . . (1956), pp. 7-8.

<sup>75</sup> United Nations, *World Iron Ore Resources* . . . (1950), chap. 5; Chardonnet, *Géographie industrielle* . . . , vol. 1 (1962), p. 185 ff.; Schurr et al., *Energy in the American Economy* . . . (1960), pp. 74-85. Schumacher, however, believed that coal was likely to come into greater prominence in the last decades of the present century. See his "Population in relation to the development of energy from coal" (1955), pp. 153, 158. Thoman also noted that in coming decades coal might regain some of its former prominence. Thoman, *The Geography of Economic Activity* (1962), p. 215. Zhavoronkov considered that since coal and petroleum are already close to exhaustion in a number of countries the primary source of power in the future must be atomic energy. See his "Chemistry and the vital resources . . ." (1967), p. 352.

<sup>76</sup> Chardonnet, *Le charbon* . . . (1948), pp. 21-57; George, *Géographie de l'énergie* (1950), pp. 123-131. On the importance of coal see also Lisichkin, "Population growth and power resources" (1967), p. 33.

<sup>77</sup> See Pratt and Good, eds., *World Geography* . . . (1950), pp. 27-42; Fanning, *Our Oil Resources* (1950), pp. 1-6. See also Thom, "Population in relation to the development . . ." (1955), p. 168.

<sup>78</sup> Foscué, "Industrialization of the Texas . . ." (1950), p. 7; Rice, "Economic developments in the south-west . . ." (1951).

<sup>79</sup> Scott, "The Witwatersrand . . ." (1951), pp. 561-563

<sup>80</sup> See, for example, Rudolph, "Chuquicamata twenty years later" (1951); Zierer, "Broken Hill . . ." (1940), pp. 103-108.

<sup>81</sup> Hubbert has noted that it is only within the last half century that water power has attained significance as a supplier of industrial power. Hubbert, "Mineral resources and rates of consumption" (1967), p. 319.

<sup>82</sup> Aubert observed, however, that the transport of electricity over long distances is costly and that new sources of hydroelectric power in sparsely populated regions can be exploited only if industries consuming power are established in the vicinity. Aubert, "L'utilisation de l'énergie hydro-électrique . . ." (1955), p. 10. See also Guyol, "Population and energy resources" (1955), p. 41.

<sup>83</sup> George, *Introduction à l'étude* . . . (1951), p. 136.

<sup>84</sup> George states that historical developments are the decisive causes of the location of population in one area rather than another. These developments stimulate the growth of systems which determine the functional relations between men and their natural environment in a still broader sense. *Ibid.* (1951), pp. 64-66.

(e) *The influence of space relationships*

41. The power of an area to attract and support population may depend also on its location in relation to other areas and to the routes of transportation between areas.<sup>85</sup> It is partly for this reason that the major areas of population concentration are commonly found on the peripheries of the continents. George noted that two thirds of the inhabitants of the temperate zones live less than 500 kilometres from the sea and almost one half of the remainder live less than 1,000 kilometres inland.<sup>86</sup> This fact has been attributed largely to the hostile conditions of the interior of continents, including deserts, steppes, high mountains and dense rain forests.<sup>87</sup> It is evident, however, that the advantages of location of the coastal areas and their immediate hinterlands at the junction of the land and ocean highways increase as world trade expands.<sup>88</sup>

42. In a locality where certain raw materials or factors of production are absent, the distance over which they must be transported if they are to be used there plays an important part in determining the volume and types of economic activities carried on. Likewise, the distance over which the finished products must be transported to markets has a great effect on costs.<sup>89</sup>

43. The importance of space relationships is especially evident in the location of certain types of economic activity at points which are strategic from the standpoint of transportation.<sup>90</sup> The beginnings of what are today areas of dense commercial and industrial population may

have been largely accidental, but their growth and ascendancy over other centres in contiguous areas have been due largely to their favourable geographic positions. For example, metropolitan New York not only has a favourable site as the leading gateway into and out of the North American continent, but is situated as favourably as any centre in its general area for linkage with the trunk-line ocean highway of the North Atlantic. Its location at the outlet of the Hudson-Mohawk corridor gave it a highly preferred position for tapping the rich hinterland during the era of inland waterways. On the strength of this factor, developing overland routes, especially railroads, sought it out as the most desired terminus.<sup>91</sup>

(f) *The composite nature of geographic factors*

44. An infinite number of combinations of physical features is found on the surface of the earth, and the significance to human activity of each factor within each combination is changing at a different rate. Some areas appear to have one dominant characteristic restricting their population growth, such as the cold temperatures of the ice-cap area. On the other hand, there are also areas possessing one single physical factor favourable to population growth, such as mineral wealth in a desert or subpolar area. There are, in addition, other areas where almost all factors appear to be favourable to the support of a high density of population. For example, the alluvial areas of south-east Asia have excellent soils, landforms and climatic conditions; the great plain of western Europe has a striking combination of excellent soils, climate, landforms, mineral resources and spatial position.

2. SOCIAL AND ECONOMIC FACTORS

45. According to the view of most geographers, the distribution of population over the globe is not determined strictly by physical factors; the influence of these factors depends on the ways of life of the people.<sup>92</sup> In James's words, "The significance to man of the physical features of the land is determined by culture ...; and therefore any change in the attitudes, objectives, or technical abilities of a people inhabiting an area requires a re-evaluation of the significance of the land".<sup>93</sup> It is generally agreed that the more complex a society becomes the less directly physical factors influence the distribution of its population. The importance of these factors in modern times is less than it formerly was.<sup>94</sup> Cases in which

standing urban sites are the great seaports which serve as contact points between large networks of inland transport and oceanic navigation". See Usher, "The steam and steel complex ..." (1949), p. 61; also Dean, *The Theory of the Geographic Location* ... (1938), chap. 5.

<sup>85</sup> Smith and Phillips, *North America: its People* ... (1940), pp. 139-154; see also Smith, Phillips and Smith, *Industrial and Commercial Geography* (1955), pp. 568-569.

<sup>86</sup> Derruau, *Précis de géographie humaine* (1961), p. 57.

<sup>87</sup> James, *A Geography of Man* (1949), p. vii.

<sup>88</sup> Pearson, *The Growth and Distribution* ... (1935), p. 13. Clarke pointed out that "Rapid urbanization is ... indicative of the diminishing influence of the physical environment upon the pattern of population distribution". Clarke, *Population Geography and the Developing Countries* (1971), p. 3.

<sup>85</sup> For accounts of the theory of spatial distribution and the contribution made by various writers, see particularly Lösch, *The Economics of Location* (1954); Isard, *Location and Space Economy* ... (1956); and his *Methods of Regional Analysis* ... (1960). See also Ponsard, *Economie et espace* ... (1955); Haggett, *Locational Analysis* ... (1966), part 1; Meyer-Lindemann, *Typologie der Theorien* ... (1951).

<sup>86</sup> George, *Introduction à l'étude* ... (1951), p. 28.

<sup>87</sup> Rudolphi, "Die Verteilung der Menschen ..." (1935), p. 337.

<sup>88</sup> Smith, Phillips and Smith, *Industrial and Commercial Geography* (1955), p. 561-569.

<sup>89</sup> Isard, in particular, has emphasized the importance of transport inputs, which in his earlier writings are referred to as "distance inputs" in view of his concern with the neglect of the distance variable by economic theorists. Isard, *Location and Space Economy* ... (1956), pp. xi, 80. He noted (p. 140) that among the various location factors, such as transport costs, labour rates, power rates etc., "only the transport factor and other transfer factors whose costs are functionally related to distance impart regularity to the spatial setting of activities". Isard's general approach differed from that of Alfred Weber in that Weber emphasized only the minimization of distance input per unit of output whereas Isard emphasized the minimization, through recourse to every economically feasible type of substitution, of the aggregate economic input of factors and distance per unit of output. See Weber's *Über den Standort* ... (1909); or Friedrich, *Alfred Weber's Theory* ... (1929). Weber restricted his analysis to the role of distance by treating the conditions of consumption, resources and labour as given. See also the discussion of Weber's and Isard's views on substitution in Richardson, *Regional Economics* ... (1969), pp. 56-58. For further discussion of the location of economic activities, see section D.

<sup>90</sup> Dechesne, *La localisation* ... (1945), chap. 9; Hoover, *The Location of Economic Activity* (1948), pp. 38 ff., 119 ff.; and his *An Introduction to Regional Economics* (1971), chap. 3; Lösch, *The Economics of Location* (1954), p. 187 ff. In the modern energy economy, Usher finds, industry locates "around primary sources of energy or at urban sites of major accessibility"; and the "out-

only physical influences affect population distribution are becoming scarcer; indeed, their existence in the world of today is doubtful.<sup>95</sup>

46. Geographers differ, however, in the relative emphasis which they place on physical and socio-economic factors. Many would agree with Pearson that the physical factors are all "of first importance";<sup>96</sup> many others would concur with George that no element of the natural environment exercises the determining role; rather the laws of population distribution, if any, are not physico-geographic laws.<sup>97</sup>

47. Among the non-physical factors which have been emphasized as having an important bearing on the distribution of population are the types of economic activities in which the people are engaged, the techniques of production, the form of social organization and the objectives which the society seeks to attain.

(a) *Influence of the types of economic activities*

48. It is obvious that the typical pattern of spatial distribution of an agricultural population is totally different from that of a population engaged primarily in manufacturing, trade, or other types of economic activity such as fishing or mining. Within a given region, as within the world as a whole, the distribution of population may change greatly with the passing of time, because of the changing relative importance of different types of economic activities.<sup>98</sup> The growth of world trade during the last 150 years has tended to increase the concentration of population in those areas which are strategically located with reference to world commodity-highways.<sup>99</sup> The growth of world trade, together with the development of manufacturing and service industries, has altered the pattern of population distribution within most countries of the world, bringing about an increasing degree of concentration and growth of population in certain metropolitan areas with an especially favourable location for these types of economic activity.

49. It has been observed that the areas of greatest population density in the world are those combining a great variety of economic activities.<sup>100</sup> This observation is explained in part by the fact that every kind of economic activity is linked in some degree with other kinds. The links are both economic and technological.<sup>101</sup> In

general, the closest links are found between industries which are close together in the sequence of production processes running from the extractive industries at one end of the scale to distribution at the other end. But the links between any two types of activity are reinforced by links between each of these and other types of activity, so that there develops a cumulative tendency for population to be concentrated in a few localities as the diversification of economic activities proceeds.<sup>102</sup> For example, following the development of certain economic activities within a given centre, the workers engaged in those activities and their dependants who settle in the locality create an increased demand for consumers' goods. This demand attracts industries which are oriented to the production of consumers' goods, together with additional workers for those industries and their dependants. The presence of these individuals may attract still other industries and workers, and so on. This cumulative process may continue until it is checked by rising transportation costs and other inconveniences which mount with the size of the community.

50. The economies of large-scale production are also important among the factors which operate, under the existing conditions of the physical environment, to concentrate a large fraction of population and economic activities in a relatively small part of the area occupied by man.<sup>103</sup>

51. Taking these factors into account, industries may be classified according to their degree of dependence upon particular locations. Four categories may be distinguished: (a) the extractive industries, which must be located where agricultural, mineral, and other forms of extractive activity can be carried on; (b) the "rooted" or "tied" industries, which, because their business is the processing or conversion of the products of extractive industry, must be situated near the extractive industries; (c) the "footloose" industries, which, being free of the heavy costs often associated with the inflow of materials and the outflow of products, are free to locate where labour or power are relatively cheap; (d) the residuary industries, which must be situated near consumers.<sup>104</sup> The first two of these categories may be combined under the heading of "resource-oriented" industries.

<sup>95</sup> George, *Introduction à l'étude* ... (1951), pp. 36, 122.

<sup>96</sup> Pearson, *The Growth and Distribution* ... (1935), p. 13.

<sup>97</sup> George, *Introduction à l'étude* ... (1951), p. 66.

<sup>98</sup> For example, Florence traces regional changes in population distribution in England which were related to the growth and decline of industries localized in different regions. See his *Economics and Sociology of Industry* ... (1964), p. 73.

<sup>99</sup> Dobby, for example, noted the great effect of the expansion of international trade following the industrial revolution on the distribution of population in south-east Asia. See his *Southeast Asia* (1966), pp. 385-386.

<sup>100</sup> See, for example, Rudolphi, "Die Verteilung der Menschen ..." (1935), p. 338; also George, *Géographie de la population* (1967), chap. 3.

<sup>101</sup> On the nature of industrial linkages see Hoover, *The Location of Economic Activity* (1948), chaps. 4-8; and his *An Introduction to Regional Economics* (1971), pp. 215-221; Dechesne, *La localisation* ... (1945), chap. 9; Florence, Fritz and Gilles, "Measures of industrial distribution" (1943); Florence, *Economics and Sociology*

*of Industry* ... (1964), p. 72; Fritz, "Markets and marketing" (1943); Ratzliff, *Urban Land Economics* (1949), especially chaps. 2, 3, 13; Hoyt, "Forces of urban centralization ..." (1941), pp. 843 ff.; Schurr and Marschak, *Economic Aspects of Atomic Power* (1950), pp. 239-246; Daly, "An approximation ..." (1940); Hildebrand and Mace, "The employment multiplier ..." (1950); Barford, *Local Economic Effects* ... (1938), pp. 5-9.

<sup>102</sup> Concerning the manner in which the pattern of location develops in a newly settled country, see Friedrich, *Alfred Weber's Theory* ... (1929), chap. 7; Engländer, "Kritisches und Positives ..." (1926); Ritschel, "Reine und historische Dynamik ..." (1927); Isard, *Location and Space Economy* ... (1956); also Haggett, *Locational Analysis* ... (1966), chap. 2.

<sup>103</sup> See a further discussion in section D below.

<sup>104</sup> Thoman, *The Geography of Economic Activity* (1962), pp. 155-158; Dechesne, *La localisation* ... (1945), chaps. 3-6; United States, National Resources Committee, *The Structure of the American Economy*, vol. 1 (1939), chap. 4 and appendix 16; Florence and Friedson, "Major groups of economic activity" (1943).

### (b) *The influence of technology*

52. The influence of the techniques of production upon the distribution of population is intimately related to that of the types of economic activities, for the development of technology is both a cause and a result of the evolution of various industries. For example, technological advances and the development of manufacturing and commerce have been inextricably entwined in the causation of the growth of urban centres throughout the world.<sup>105</sup>

53. Technology, however, has an important independent influence, for changes in the techniques employed in any type of economic activity may open up new areas which formerly held little possibility of human habitation, or render unattractive the sites which formerly were advantageous. Striking examples are the development of irrigation turning desert areas into fertile farming lands, and the development of means of transportation increasing the capacity of the subpolar regions and other remote areas to support population.<sup>106</sup>

### (c) *The influence of social policy and social organization*

54. Within limits, men can make their own decisions regarding the places which they will inhabit, and the political State may influence the size and internal distribution of the population in the area which it controls. The distribution of population is thus affected by the objectives which the society strives to achieve and by the forms of social action which are taken to achieve those objectives. The distribution of population over the earth has unquestionably been affected to an important degree by the efforts of Governments to control migration across international frontiers. Governments have also tried on many occasions to alter the distribution of population within national boundaries for various purposes: for example, to improve their military strength and security, to tap unused resources in the sparsely populated parts of the country, or to achieve greater self-sufficiency within the economy. In many cases the measures taken to implement these policies have undoubtedly had a significant effect upon the internal distribution of the population.<sup>107</sup>

55. It has been observed that the links among various types of economic activities create obstacles to the relocation of population. If the workers in a given locality are engaged in several industries which are closely linked with one another, the movement of workers engaged in any one of these industries to a new location may be difficult unless workers in the other industries are moved at the same time. Relocation of different industries simultaneously may be difficult even with the active assistance of the Government.<sup>108</sup>

<sup>105</sup> See section D below.

<sup>106</sup> See for example, George, *Introduction à l'étude ...* (1951), pp. 38, 70; Barbour, "The Nile basin ..." (1969), pp. 92-108; Tuan, *Man and Nature* (1971), p. 40.

<sup>107</sup> Dechesne, *La localisation ...* (1945), chap. 14; Hoover, *The Location of Economic Activity* (1948), chaps. 12-13 and part 4. See also section E of the present chapter.

<sup>108</sup> See, for example, Spengler, "Regional differences and the future ..." (1941), pp. 479-481.

56. The measures which may be taken to implement social policies regarding the distribution of population depend in part upon the existing form of social organization. Some geographers have greatly emphasized this factor as a determinant of the pattern of population distribution. Different societies, they have pointed out, may be subject to different principles of population distribution. George, for example, has contrasted these principles as they apply to industrialized, capitalistic societies and to socialist societies. In the former, the population clusters about the sources of energy and industrial raw materials. The highly specialized occupations followed in industrial societies, the dependence on food brought from great distances, and the mechanization of agriculture contribute to the excessive concentration of population in a few vital centres. The planned relocation of population under socialism, according to George, tends to produce a more even distribution.<sup>109</sup>

### 3. DEMOGRAPHIC FACTORS

57. Changes in the distribution of world population take place through the medium of births and deaths in various areas and of migration between areas. The birth and death rates and the currents of migration in different parts of the world may be regarded in the long run largely as being determined by social, economic, cultural and geographic factors. However, for a realistic consideration of the factors that determine the changes of population distribution during short or moderately long periods, it is useful to regard the birth rates, death rates and migratory movements themselves as factors, bearing in mind that they in turn are influenced by other factors.

58. The existing distribution of the population also has to be recognized as a factor of the greatest importance in determining the future population distribution, especially at a time not far distant. The longevity of men and their relative immobility under normal conditions limit the changes which can take place within a few years or decades; only in the course of generations can radical changes be brought about. Moreover, a distribution once established has a powerful influence upon the relative attractiveness of various areas for human habitation, both from economic and other points of view.

#### (a) *Influence of population distribution on the location of economic opportunities*

59. Economic studies of the effects of the existing population distribution upon the location of industries

<sup>109</sup> George, *Introduction à l'étude ...* (1951), pp. 127-140, 142-143. However, he points out that there is still a tendency toward concentration of population under socialism and that more than one quarter of the population of the USSR is found in the large industrial regions comprising Moscow, the Urals and the Ukraine. George, *Géographie de la population* (1967), p. 64. Others have noted that under socialism the planned reallocation of population and productive activities should result in a more uniform area distribution of people than could result under capitalism. Balzak, Vasyutin and Feigin, eds., *Economic Geography ...* (1949), pp. 109-110, 130-132, 167-171, 172-182, 187-196. On p. xl of this work Stalin was quoted as writing: "The geographic environment is incontrovertibly one of the unchanging and indispensable conditions of the development of society. ... But its influence is not the determining influence ... since society changes and develops incomparably faster than does the geographic environment."

have been rather few and for the most part they have dealt with the topic only in general terms. The results imply that these effects occur for two reasons. First, since the spatial distribution of consuming power is in part determined by the distribution of population, and since a large fraction of economic activity is consumer-oriented, a given distribution of population, whatever its origin, will immediately dominate the distribution of consumer-oriented economic activities.<sup>110</sup> Secondly, the distribution of the population in relation to resources may affect the geographical variations of wage rates, so that the cost of various types of labour inputs will be lower in some areas than in others. The areas where wages are relatively low, and where (consequently) profit opportunities appear in certain industries where wages are a primary element of production costs, will attract such industries unless the labour-cost advantage is counterbalanced by disadvantages.<sup>111</sup>

60. For reasons which have already been stated, an area selected for the location of certain economic activities may acquire additional qualities which make it attractive to still other industries. If this is the case, a cumulative process may get under way whereby the area in question may become transformed into a centre of industry. It may happen, therefore, that the presence of population in a certain area will be instrumental in attracting other economic activities which stimulate the area's further industrial development.<sup>112</sup>

<sup>110</sup> Cities which owe their origin to the initial assembly of consumers in search of pleasant climates, or composed largely of military and/or government personnel, are instances in which the initial location of population exercised a very great influence. The urban history of Europe and Asia provides many examples. Thoman has pointed out that most of the present and former European capitals have thriving diversified manufacturing industries that are, or once were, largely oriented toward markets. Thoman, *The Geography of Economic Activity* (1962), pp. 156-157. For an account of the manner in which location of certain economic activities is affected by the attractiveness of a district as a place of residence, see Winsemius, "Wanderungen und Verbrauch ..." (1940). In so far as the attractiveness of a community may be affected by changes in its size, these changes may check or foster further growth. Various authors have considered the question of desirable size of cities. See, for example, Evans, "The pure theory of city size ..." (1972); Von Böventer, "Urban hierarchies ..." (1971); Stanford Research Institute *et al.*, "Costs of urban infrastructure ..." (1969); Gottman, "Urban sprawl ..." (1967), pp. 10-12; Northam, "Population size, relative location ..." (1969); Duncan, "Optimum size of cities" (1951); Perevedentsev, "Goroda i gody" (1969); and his "Kakoi gorod vygoden?" (1967); Khorev, "Kakoi gorod nuzhen?" (1969); and his *Gorodskie poseleniia SSSR* ... (1968), particularly pp. 95-138; Roterus, "Effects of population growth ..." (1946); Clark, "The economic functions of a city ..." (1945); and Thorndike, *144 Smaller Cities* (1940), particularly chaps. 2 and 4.

<sup>111</sup> See, for example, Dean, *The Theory of the Geographic Location* ... (1938), pp. 28-29; Ohlin, *Interregional and International Trade* (1967), chap. 11; Isard, *Location and Space Economy* ... (1956), chap. 6. Lewis in "The industrialization ..." (1950) discussed the principle of comparative advantage in considering the industrial prospects of the West Indies. Derruau, *Précis de géographie humaine* (1961), pp. 375-376, describes the migration of the cotton textile industry from New England to the South in the United States, partly owing to the cheaper labour supply in the latter region. See also Sickie, *Planning for the South* ... (1943), chap. 4.

<sup>112</sup> See, for example, Derruau, *Précis de géographie humaine* (1961), p. 377. See also section D below. The rate of growth of the

61. The initial population distribution has an especially important bearing on the processes of industrialization of economically underdeveloped countries. The average density and the degree of concentration or dispersion of population in such countries affect the types of industrial development which can most readily be achieved in the early stages, since these demographic factors are relevant to the supplies of labour that can be assembled in potential manufacturing sites and to the sizes of the markets for the manufactured products.

(b) *Processes of population redistribution in relation to economic opportunities*

62. Variations of natural increase rates are related to economic conditions, but the relationship at least in the short run is not necessarily such as to bring about high rates of natural increase in areas where economic opportunities are plentiful, or low rates where opportunities are scarce. On the contrary, relatively large excesses of births over deaths are commonly found in areas of comparatively poor economic opportunities. The relationships of migration to economic conditions, on the other hand, are generally such as to bring about migratory increases of population in areas of relatively great opportunities, and migratory losses in areas of scanty opportunities. As shown in chapter VII and in section D of the present chapter, migrants move, as a rule, towards areas where they expect to be able to command higher earnings than they can get in their home communities. Thus migration acts as a mechanism for partial adjustment of population distribution to the location of economic opportunities. It is further indicated that the number of migrants moving between any two points tends to vary inversely with the distance between them. The effect of the distance factor is conditioned by the distribution of economic opportunity in space. How far the representative migrant moves is said to depend upon such conditions as his knowledge of job opportunities, the location of communities in a stage of industrial development similar to that of his home community, the pattern of spatial distribution of opportunities, and so on.

63. The spatial mobility of population within countries has greatly increased in modern times. Consequently, other conditions being given, the distribution of population exercises less influence than formerly upon the spatial distribution of economic activities at the intranational level. It is at the international level that the influence of the distribution of the population upon that of economic activities is greatest, for the international mobility of labour is much lower than its intranational mobility. The international wage structure is affected accordingly, and this effect in turn influences the international distribution of economic activities.

64. An increase in trade between areas may serve in lieu of migration as a mechanism in bringing about an

expanding centres will be conditioned by the amount of net migration to or from abroad. For example, as Thomas has shown, if there is net emigration abroad, the rate of growth of urban centres within the country will be lower, *ceteris paribus*, than if there is no such emigration. Thomas, *Social and Economic Aspects of Swedish* ... (1941), pp. 88-92, 166 ff., 365 ff. For a discussion of this view and related problems see Skaug, *Memorandum on Fluctuations in Migration* ... (1937), especially pp. 185-194.

adjustment between the distribution of population and economic activities. The feasibility of this alternative depends on the possibility of increasing economic opportunities in the areas of relative surplus of labour, through investment of capital or development of labour-intensive industries which enable these areas, in effect, to export their excess labour in the form of goods. To the extent that it is feasible, this alternative to migration is especially attractive at the international level, in view of the economic, social and political difficulties commonly involved in international migration.

#### 4. CHANGES IN FACTORS AFFECTING THE DISTRIBUTION OF POPULATION IN MODERN TIMES

65. During modern times the factors affecting population distribution have been undergoing several major types of changes which have interacted to alter considerably both the relative numbers of people in various regions of the world and the distribution of population within countries. First, technological advances and changes in the industrial structure of the world economy have freed a large proportion of the people from their former dependency upon the land and other place-bound natural resources. Secondly, the changes in technology and in consumers' wants have re-enforced the tendency for economic opportunities and population to be concentrated in certain localities, particularly in the great metropolitan agglomerations. Thirdly, the desires of the people and the policies of Governments with reference to the growth and distribution of national populations have been shifting; and there has recently been an increased degree of governmental control, especially in the countries with planned economies. Fourthly, the pattern of geographical variations in birth and death rates has been changing; the rates of natural increase have fallen in highly industrialized countries and have been rising in economically less developed countries and in many countries the urban and rural rates are no longer very different. In the first countries to industrialize, the effects of intranational differences in rates of natural increase was greatly modified by migration within countries, particularly by migration from rural to urban areas, bringing about a rapid population growth in the cities of many countries in spite of low urban rates of natural increase. In the developing countries today, where urban rates of natural increase tend to approximate rural rates, the relative contribution of internal migration to urbanization is generally less significant. International migration, since the end of the massive movements that characterized the *laissez-faire* period, has had greatly reduced influence as a factor of change in the relative sizes of population in most countries.

66. The power of land and other natural resources to determine the distribution of population has diminished with the progress of industrialization. Man is no longer dependent upon the organic products of land to the extent that he was formerly.<sup>113</sup> Similarly, in the case of mineral

resources, although the Industrial Revolution initially increased their population-pulling power and although they continue to be of fundamental importance in modern economies, they no longer govern the location of population to the former extent. The proportion of the labour force engaged in agricultural and mining activities is today smaller than formerly. An increasingly large proportion of the equipment utilized today is man-made and can therefore be produced and located wherever man decides. In consequence of these changes, the proportion of the labour force of industrialized countries, whose location is relatively independent of land and natural resources, may well be two or three times what it was in the beginning of the Industrial Revolution.<sup>114</sup>

67. Among the circumstances contributing to the increasing concentration of population on a few sites, four in particular may be mentioned. First, improvements in transportation have diminished the cost of moving raw materials and sources of energy to manufacturing centres.<sup>115</sup> Secondly, technological change has increased economies of scale, agglomeration etc., which make for the spatial concentration of economic activities.<sup>116</sup> Thirdly, the proportion of the national income expended for services and manufactures not heavily dependent on place-bound resources has steadily increased as *per capita* income has risen.<sup>117</sup> Fourthly, the mobility of labour within countries has increased.<sup>118</sup> These four changes, together with those described in the preceding paragraph, have greatly diminished man's dependency upon land and natural resources and have extended his range of choice in economic activities, at least when he acts collectively.

<sup>114</sup> For example, in the United States in 1935 not more than 40 per cent of the labour force was directly or indirectly oriented to natural resources. A century and a half ago this fraction must have been twice as high. Spengler, "Regional differences and the future . . ." (1941), pp. 480-481; see also pp. 478-481 for a discussion of the possibilities of modifying equipment.

<sup>115</sup> Hoover, *The Location of Economic Activity* (1948), chap. 5, especially pp. 84-89. Ullman, "Regional development . . ." (1964), p. 159. Alonso noted that in the long run transportation tends to become cheaper and more efficient, with the result that industries become more foot-loose and less transport-oriented. Alonso, "Location theory" (1964), pp. 100-101. For estimates of the effects of air transport, see Isard and Isard, "Economic implications . . ." (1945). For an account of the effects of transport improvements upon the scope of the European and the world economy, see Prokopovitz, *L'industrialisation des pays . . .* (1946), chap. 3 and pp. 33-42, 116-118, 215-219.

<sup>116</sup> Ullman, "Regional development . . ." (1964), p. 158. Steindl, *Small and Big Business . . .* (1945); Florence, *The Logic of Industrial Organization* (1933), chap. 1, and his *Investment, Location, and Size of Plant* (1948). Florence found that concentration within particular areas is characteristic of industries with relatively low transport costs and (partly because of this) large plants, while dispersal among raw material or market areas is characteristic of industries with relatively high transport costs and (partly because of this) small plants. He found also that, even though the plants composing an industry may be relatively small, the industry tends to be concentrated if economies for individual plants are produced by their juxtaposition.

<sup>117</sup> On the changes in consumption as reflected in the occupational composition of the labour force, see, for example, Clark, *The Conditions of Economic Progress* (1960).

<sup>118</sup> Lee offered several explanations for the secular increase of migration rates, among them the increasing diversity of areas, increasing diversity of people, and improving technology which reduces obstacles to migration. Lee, "A theory of migration" (1966), pp. 53-54.

<sup>113</sup> A century ago, as Mather observed, of all the things men used, nearly 80 per cent were "derived from the plant and animal kingdoms, with only about 20 per cent from the mineral kingdom". Mather, *Enough and to Spare . . .* (1944), pp. 55-56.

These changes, however, have entailed or have been accompanied by changes in production necessitating a high degree of concentration of population at the sites chosen.

## B. Internal migration

68. Two of the three components of population change—fertility and mortality—are treated in preceding chapters, and the third component—migration—in so far as its international aspects are concerned, is treated in chapter VII. Internal migration, which has no direct effect on a country's total population size and growth, but is intimately related to population distribution within a country, and particularly to the process of urbanization, is discussed in the present chapter.

### 1. DEFINITIONS

69. There is no one universally accepted definition of migration. Noting that "the concept of migration is applicable only in the case of relatively settled populations", the United Nations *Multilingual Demographic Dictionary* defines it as a form of spatial mobility between one geographical unit and another involving a permanent change of residence.<sup>119</sup> Internal migration in this sense is residential mobility from one unit to another within the same country. Such a definition excludes not only the wanderings of nomadic populations, but also seasonal migration and the movement back and forth of persons with more than one residence. In principle, visitors, tourists and commuters are excluded because no change of residence ordinarily takes place. In practice, many borderline cases occur where it is not always possible clearly to distinguish migratory from non-migratory movement. The mover himself is not always sure of his intentions and, even when he is in fact changing his residence, may nourish the hope of some day returning to his place of origin. The working or operational definition that the analyst has to use generally depends on the kind of data at his disposal. When the principal source of data is the population census, migration is conveniently defined as a change in the usual place of residence from one administrative unit to another.<sup>120</sup>

70. A demographic definition<sup>121</sup> of internal migration in terms of change of residence across boundaries of administrative areas has various advantages and disadvantages. Among the disadvantages are the risk of non-comparability over time due to changes in the boundaries of the areas and the distortion introduced into measures of migration because of great differences in size and shape among these areal units.<sup>122</sup> An important

advantage of these units is that much useful information is usually available on the characteristics of the places of origin and destination which permit a better analysis of the factors associated with the migratory movements.

### 2. PRINCIPAL SOURCES OF DATA

71. Although various government institutions, for purposes unrelated to the study of population movements, keep records of changes of residence which can be used, in the absence of more adequate data, to infer the volume and direction of migratory streams,<sup>123</sup> the three main sources of information on internal migration are censuses, sample surveys and population registers. Population registers, however, are maintained at present in only a few countries and published data on internal migration from this kind of source are largely confined to the volume of in-migration and out-migration for component areas.<sup>124</sup>

72. Until recently, almost all migration research has been concentrated on the analysis of census data. There is currently a tendency, however, to supplement these sources by collecting data in special sample surveys devoted to the study of migration.<sup>125</sup> These have so far been carried out primarily in connexion with migration to large metropolitan areas. The basic procedure involves holding interviews with a representative sample of metropolitan residents, with a list of special questions being asked of persons found to be in-migrants to the metropolitan area. Through this approach it is possible to go beyond the usual migration information on volume, direction, etc. and to test a large number of demographic and socio-economic hypotheses related to migratory behaviour.<sup>126</sup>

73. Most studies of internal migration have as their main objective the measurement of the volume and per-

<sup>119</sup> Changes of legal residence noted for voting records or in connexion with school transfers or social insurance and rationing programmes have been used as an index of internal migration. Such sources may include movements other than migration or they may exclude movements which should be counted as migration. See United Nations, *Multilingual Demographic Dictionary* ... (1958), p. 47.

<sup>124</sup> United Nations, *Manual VI. Methods of Measuring Internal Migration* (1970), pp. 3-4. For examples of studies using population register data, see Meerdink, "Internal migration in Amsterdam" (1962); Wendel, *A Migration Schema* ... (1953); Goldstein, "The extent of repeated migration ..." (1964), pp. 1121-1131; Hama, "Kokunai jinko ido ..." (1961), chap. 4; Kono, "Evaluation of the Japanese population register data ..." (1971).

<sup>125</sup> The distinction between census and sample survey data on migration is that the census operation is generally confined to a very limited number of questions on migration, whereas a specialized sample survey can delve into the antecedents of each migratory movement. Migration histories obtained in a 1959-1960 sample survey in England and Wales have been analysed by Friedlander and Roshier. See their "A study of internal migration ..." (1966), part 2. For the United States, see Taeuber, Haenszel and Sirken, "Residence histories ..." (1961); Taeuber, Chiazze and Haenszel, *Migration in the United States* ... (1968). On advantages and disadvantages of survey data, see Shryock, Siegel *et al.*, *The Methods and Materials of Demography*, vol. 2 (1971), p. 620.

<sup>126</sup> A number of these surveys have recently been carried out in Latin American cities; see, for instance, United Nations, Centro Latinoamericano de Demografía, *Encuesta sobre inmigración* ... (1964); United Nations, "Demographic aspects of urbanization ..." (1961); Peru, Dirección Nacional de Estadística y Censos, *Encuesta de inmigración de Lima metropolitana* (1966).

<sup>119</sup> United Nations, *Multilingual Demographic Dictionary* ... (1958), p. 46.

<sup>120</sup> See, for example, United Nations, *Manual VI. Methods of Measuring Internal Migration* (1970), p. 1. Also, Shryock, *Population Mobility* ... (1964), p. 8.

<sup>121</sup> Called "census definition" by De Jong, *Appalachian Fertility Decline* ... (1968), p. 57.

<sup>122</sup> See, for example, United Nations, *Manual VI. Methods of Measuring Internal Migration* (1970), p. 1; Thomlinson, "Methodological needs in migration research" (1962), p. 60.

haps some of the characteristics of migratory movements during a specified interval or period of time.<sup>127</sup> When the volume and direction of the movements have been estimated from census data, the knowledge of the characteristics of the migrants can be combined with data on the characteristics of the place of migration origin and migration destination, in order to analyse the determining factors underlying the movements.

### 3. METHODS OF MIGRATION MEASUREMENT

74. The techniques most frequently used for measuring or estimating migration are conveniently classified as either "direct" or "indirect".<sup>128</sup> The direct methods are those which have recourse to data indicating the movements of the migrants themselves—those who change residence across migration-defining boundaries, whereas the indirect methods involve estimates inferred from the difference between the observed change in population between two dates and the change due to natural increase.<sup>129</sup>

75. The direct method most accessible in many countries involves comparing data on place of birth with current place of residence in order to obtain a measure of life-time migration, that is, of the number of persons who have migrated since their birth from one area to another. This method permits measuring the streams of migration in each direction between any two areas and, of course, the net migration between the areas. Furthermore, the total in-migration and out-migration as well as the net migration for any area can be obtained; in principle, the census characteristics of the migrants in any given migration stream can also be identified. Among the limitations of this method are the following: the time period is indeterminate, depending on the years lived by each individual; it reveals only the net movement of each person so that migrants who returned to their place of birth are excluded, as are the intervening movements of persons who had not moved directly from place of birth to current residence; it includes only the movements of migrants who survive to the end of the period and have not left the country; and it excludes the internal movements of persons born outside the country.

76. A refinement of this method serves to measure the migration during the interval between two censuses as the difference between the movements measured by each of

the two censuses.<sup>130</sup> As Elizaga has pointed out,<sup>131</sup> estimates obtained in this way underestimate the magnitude of the migration in question because of the inclusion in the earlier and not in the latter census of lifetime migrants who died during the intercensal period. This limitation is overcome to some extent when intercensal survival rates are used as a corrective factor.<sup>132</sup>

77. Other direct methods frequently used are those that depend on the insertion in the census schedule of a question as to (a) place of residence at a specified prior date, or (b) duration of present residence. Either of these methods has advantages and drawbacks. The first method permits the estimation of gross and net migration during a precisely identified time interval, but does not reveal the intervening movements of persons with more than one move during the interval and misses migrants who have died in the interval.<sup>133</sup> The second, or duration-of-residence method identifies the year of migration of all in-migrants residing in each area of enumeration, but provides no information on area of origin. When duration of residence data are used in conjunction with birthplace data, in-migrants can also be classified into migrant cohorts according to place of birth.<sup>134</sup>

78. The indirect methods of measuring migration are employed ordinarily where it is not possible to determine migration so directly. Basically, two indirect methods can be distinguished: the vital statistics method and the survival ratios method.<sup>135</sup> Both yield estimates of net migration obtained residually as that part of the observed change in population between two dates that is not attributable to natural increase.

79. The vital statistics method estimates intercensal net migration by adding registered deaths and subtracting registered births from intercensal population change. When age-specific net migration is being estimated, it suffices to use death data only except for those age cohorts born during the intercensal period. As compared with the survival ratios method, this has the merit of being "potentially exact".<sup>136</sup> An important limitation is that often the necessary data are not available or not

<sup>130</sup> For examples of the use of this method, see Elizaga, "Internal migrations ..." (1965), p. 146; Shryock, *Population Mobility* ... (1964), pp. 20-21; and Ominde, "Some aspects of population ..." (1968).

<sup>131</sup> Elizaga, "Internal migrations ..." (1965), p. 146.

<sup>132</sup> For a discussion of various alternative procedures for accomplishing this adjustment, see United Nations, *Manual VI. Methods of Measuring Internal Migration* (1970), pp. 5-12. See also Eldridge and Kim, *The Estimation of Intercensal Migration* ... (1968).

<sup>133</sup> For examples of the use of this method, see Elizaga, "Assessment of migration data ..." (1965), pp. 79-81, 97-104; and Jaffe, *Handbook of Statistical Methods* ... (1951), pp. 180-184.

<sup>134</sup> See Zachariah, "Bombay migration study ..." (1966), pp. 378-392, for a methodological evaluation of the reliability and validity of duration-of-residence data and for an example of their use in combination with place-of-birth data.

<sup>135</sup> For an application of these methods to data for the United States and comparison of results, see Eldridge, *Net Intercensal Migration for States and Geographic Division* ... (1965), pp. 82-99.

<sup>136</sup> Lee and Lee, "Internal migration statistics ..." (1960), p. 692. See also Siegel and Hamilton, "Some considerations in the use of the residual method ..." (1952); Stone, "Evaluating the relative accuracy ..." (1967); Hamilton, "The vital statistics method ..." (1967).

<sup>127</sup> Relatively few migration studies have used a longitudinal method of analysis in which the residential histories of individuals provide a basis for studying migration. See Taeuber, "Cohort migration" (1966). For an example of the longitudinal analysis of migration data from Swedish population register data, see Wendel, *A Migration Schema* ... (1953).

<sup>128</sup> For a detailed description of these direct and indirect methods of internal migration measurement from census data, see, for example, Shryock, Siegel *et al.*, *The Methods and Materials of Demography*, vol. 2 (1971), pp. 625-637; Elizaga, "Assessment of migration data ..." (1965); Shryock, *Population Mobility* ... (1964); Jaffe, *Handbook of Statistical Methods* ... (1951), chap. 6; and Bogue, "Internal migration" (1959), pp. 491-499.

<sup>129</sup> United Nations, *Multilingual Demographic Dictionary* ... (1958), p. 47.

sufficiently accurate. The survival ratios method uses age-specific intercensal survival ratios so as to eliminate the number of intercensal deaths in each age cohort. Estimated net migration is the difference between the observed size of each cohort at the end of the intercensal period and its expected size if only mortality had acted upon it.<sup>137</sup> The most appropriate method to use in any particular instance depends mostly on the nature and the quality of the available data. Since these vary considerably from one country to another, it has not proved feasible to formulate simple prescriptions fitting all circumstances. Other things being equal, the direct methods are generally preferred over the indirect methods.

#### 4. PRINCIPAL INTERNAL MIGRATIONS OF MODERN TIMES

##### (a) *Major migration movements*

80. There are many forms of internal migration and their nature has varied over time and in different cultures.<sup>138</sup> Some of these forms of movement are overlapping. For instance, migration from one region of a country to another may be from a rural to an urban area, from one rural area to another etc. Furthermore, most of the research done in this area has been of an *ad hoc* nature, oriented to specific problems, and producing results that are not comparable with those of other studies. It is not feasible, therefore, to present a systematic discussion of all types of internal migration, nor even of the principal types in all countries of the world. The movements summarized here refer mostly to the larger countries or to studies of international scope on migration within several countries of the same region. Examples of studies in some smaller countries are also provided.

81. One feature of the current situation is the diminishing importance of one kind of internal movement, frontier settlement migration, that reached its largest scope in several parts of the world during the nineteenth century.<sup>139</sup> By contrast, the rural-to-urban movement has been accelerating in almost all countries of the developing regions, while continuing more or less unabated in the more advanced countries. In these latter countries, the spread of urbanization is usually marked by the growth of urban and suburban fringes and of small rural non-

farm residential communities, much of it due to a large-city exodus.<sup>140</sup>

82. The settlement of Europeans in the Americas entailed some of the greatest migrations between regions of the same country during modern times, particularly the transcontinental migration within the United States.<sup>141</sup> During the nineteenth century, the prevailing direction of migration was from the east to the west. This was the era of settlement of the vast new lands beyond the Mississippi River. The westward movement in the United States continued during the twentieth century, but following the occupation of virgin lands, the character of this movement was greatly changed. Only California continued to receive a large, uninterrupted stream of migrants. Migration into the other western states slackened after 1910 and only partially recovered its momentum during the Depression and war years of the 1930s and 1940s. The movement from east to west was crossed by a new movement from south to north, stimulated by the growing need for industrial and commercial workers in the northern cities.<sup>142</sup> Interregional movements, previously motivated by quests for land in rural areas, increasingly took on the character of migration from rural areas and small towns to big cities.

83. The growth of cities in the United States reached very large dimensions after about 1880. The rapid growth has continued into the present century, but the rate of growth has declined gradually. During the economically depressed 1930s, the rate of urban growth barely exceeded the increase in rural population (7.9 per cent as compared with 6.4 per cent),<sup>143</sup> but a high tempo of urbanization was resumed after about 1940.

84. Migration from rural areas has played an important part in the growth of cities in the United States. During the period 1900-1920 the total increase in the urban population was 24 million, 9 million of which is estimated to have been contributed by migrants from farms and villages.<sup>144</sup> The United States Bureau of Agricultural Economics estimated that during the decade 1920-1930, the net loss in the farm population through migration amounted to 6 million persons. In the depressed decade

<sup>140</sup> Horstmann, "Rural-urban migration . . ." (1967), pp. 496-498; Bogue, *Principles of Demography* (1969), pp. 766-767.

<sup>137</sup> Although the survival ratios are most often applied to the cohorts in the first of the two censuses (forward surviving), reverse surviving or an average of deaths obtained by forward and by reverse surviving are also resorted to. Either of these procedures involves at least some small error in the estimate of net migration because of failure to account exactly for the deaths of migrants. In the case of forward surviving, for example, the estimate of net migration excludes both in-migrants and out-migrants not surviving to the end of the intercensal period. Lee and Lee, "Internal migration statistics . . ." (1960), p. 692; United Nations, *Manual VI. Methods of Measuring Internal Migration* (1970), pp. 25-26. See also Zachariah, "A note on the census survival ratio . . ." (1962). For an example of the application of the survival ratio method, see Zachariah, *A Historical Study of Internal Migration in the Indian Sub-Continent . . .* (1964).

<sup>138</sup> See section D for a brief discussion of migration typologies.

<sup>139</sup> At the 1965 World Population Conference it was observed that almost everywhere in the world this frontier phase of population distribution had already ended or was drawing to a close. Bogue, "Internal migration with special reference . . ." (1966), p. 162, and Zachariah, "Internal migration . . ." (1966), p. 165.

<sup>141</sup> Three major studies of migration history in the United States are Goodrich *et al.*, *Migration and Economic Opportunity* (1936); Shryock, *Population Mobility . . .* (1964); and Kuznets and Thomas, eds., *Population Redistribution and Economic Growth . . .* (1957, 1960 and 1964). The last study has been updated and summarized by Thomas, "Internal migration in the United States . . ." (1967). For a brief summary of the main patterns of population redistribution in the United States, see Taeuber, "Population dynamics and population pressures . . ." (1970), pp. 65-67. For the decade 1950 to 1960 see Bowles and Tarver, *Net Migration of the Population . . .* (1965-1966). For estimates from 1800 to 1870, see Lebergott, "Migration within the U.S. . . ." (1970). Two recently issued monographs based on statistics from the 1961 and earlier censuses in Canada have examined the main trends and characteristics of internal migration in that country. See Stone, *Migration in Canada . . .* (1969); and George, *Internal Migration in Canada . . .* (1970).

<sup>142</sup> For a history of Negro emigration from the South in the United States, see Hamilton, "The Negro leaves the south" (1964).

<sup>143</sup> Hauser and Taeuber, "The changing population . . ." (1945), p. 17.

<sup>144</sup> Gillette, *Rural Sociology* (1928), p. 94.

of the 1930s the net movement from farms was about 3.7 million.<sup>145</sup> After the depression decade, net migration from farms returned to previous high levels. It amounted to 11.4 million in the 1940s and 10.1 million in the 1950s, equivalent to net average annual emigration rates of 4.4 per cent and 5.5 per cent respectively.<sup>146</sup> The continuing rural exodus was associated not only with migration to urban areas but also with residential transfers away from city centres to urban fringe and rural non-farm areas.<sup>147</sup>

85. The flow of people from the European to the Asian part of Russia, which likewise continued over numerous decades, is similar to the American westward "frontier" movement. At the end of the nineteenth century the agricultural colonization of Asian Russia took on greater proportions than ever before. Much of this new settlement was in the forest-steppe regions and along the Trans-Siberian Railway.<sup>148</sup> It is estimated that more than 5 million peasants migrated to Siberia during the thirty-year period preceding the First World War.<sup>149</sup> Included among the migrants were Russians, Ukrainians, Byelorussians, Tartars and other peoples.<sup>150</sup> At the same time another population movement took place within the European part of the Soviet Union towards the south-east region of the Ukraine. During the nineteenth and early twentieth centuries, the migration to the south absorbed some 12 to 13 million persons.<sup>151</sup>

86. Planned migration in the USSR began in the 1920s. Between 1926 and 1939, 3 or 4 million people moved from the most heavily populated areas of the central districts of the European part of the Soviet Union to the Urals region, Siberia, and the far eastern region.<sup>152</sup> The number of these migrants amounted to approximately one fifth of the natural increase in the country's population.<sup>153</sup> Between 1926 and 1967 the proportion of the Soviet

population residing beyond the Urals (Siberia, central Asia and the far east) rose from 8 per cent to 15.5 per cent.<sup>154</sup> Migration to selected settlements in the far north has been encouraged by various incentives. The proportion of Soviet population in the far north increased from 1 per cent in 1926 to 2.5 per cent in 1967.<sup>155</sup>

87. During the last intercensal period (1959-1970), the geography of population increase differed substantially from that of the preceding twenty years when population growth in the Urals, Siberia and the far east had been substantially greater than the average for the Soviet Union as a whole. Despite the fact that natural increase in Siberia was higher than the all-Union average, Siberia's share in the country's population has declined, and the population outflow from Siberia is increasing.<sup>156</sup> In the nine years following the 1959 census, the excess of outflows over arrivals came to 595,000 people in the Urals and 390,000 in western Siberia. Eastern Siberia and the far east had a positive migration balance of 90,000 people, mainly in Magadan Province and the Yakut Autonomous Soviet Socialist Republic, but in certain years the migration balance was negative here also.<sup>157</sup> The recent outflow from Siberia is attributed to the fact that the comforts of living in this area are inferior to other areas of the country.<sup>158</sup> Housing and public services are less adequate than elsewhere and the climatic conditions are difficult. Moreover, it has been determined that, except in the far north, the average level of real wages is lower in Siberia than elsewhere.<sup>159</sup> Thus an anomalous situation has arisen in the Soviet Union where recent out-migration has been mainly from rural areas which already have labour shortages rather than from rural areas where labour surpluses exist.<sup>160</sup>

88. Rapid growth of cities has also been an outstanding feature of the demographic development of the Soviet Union, a consequence chiefly of the migration from rural areas.<sup>161</sup> Internal migration within the European part of the USSR has been largely a movement to cities;

<sup>145</sup> United States Bureau of Agricultural Economics, *Farm Population Estimates, United States* ... (1946), p. 5; Bernert, *Volume and Composition of Net Migration from the Rural-Farm* ... (1944), p. 1.

<sup>146</sup> Beale, "Rural depopulation in the United States ..." (1964), pp. 265-266.

<sup>147</sup> Bogue, *Principles of Demography* (1969), p. 766; and his "Population growth in the United States" (1963), pp. 90-91.

<sup>148</sup> Kozlov, "Migratsii naseleniia" (1964), p. 68; Kulischer, *Europe on the Move* ... (1948), p. 210. According to Lorimer in *The Population of the Soviet Union* ... (1946), pp. 44-45, the mobility of the Russian population in the eighteenth and early nineteenth centuries was high compared to that of most European countries.

<sup>149</sup> Sonin, "Voprosy pereseleniia ..." (1940), p. 83; and his "Resettlement of population ..." (1940), p. 78. See also Barnes, "Eastward migration within the Soviet Union" (1934); Lorimer, *The Population of the Soviet Union* ... (1946), pp. 47-48. Kulischer mentioned an estimate of 4 million peasants crossing the Urals during the nine years preceding the First World War: Kulischer, *Europe on the Move* ... (1948), p. 110.

similarly the movement from the European to the Asian part, which was mostly agricultural during the Czarist régime, has become predominantly industrial and urban since the Revolution.<sup>162</sup> The total growth of the urban population in the Soviet Union between the 1926 and 1939 censuses was 29.8 million, of which 18.5 million, or 62 per cent was accounted for by migration from rural to urban areas.<sup>163</sup> The percentage contribution of migration to total urban growth was almost the same between the 1939 and 1959 censuses.<sup>164</sup> This migration from rural to urban areas took many different directions. During the 1926 to 1939 period the main movement was to the largest of the older industrial centres. Another heavy flow took place towards the northern and more particularly the eastern areas of the country. The most extensive emigration was observed in the densely populated districts of the Ukraine, in both the black-earth and non-black-earth zones. Some of the planned migration of rural population was directed towards the sparsely populated outlying districts in the European north and the far east where the rural population actually increased. The migratory flow between 1939 and 1959 sometimes brought rural residents to towns in the same region and sometimes to towns in nearby regions or in other parts of the country. During this period also, despite a general decline of the rural population, there were several areas in which increases were reported. In the Republics of central Asia this was due to natural increase rather than to in-migration. In sparsely populated eastern regions, where virgin and fallow lands have been developed, there was an increase of the rural population attributable to migration. The rapid growth of some of the largest Soviet cities has made it necessary to take steps, such as a ban on the construction of new enterprises and control of further in-migration, to restrict their continued expansion.<sup>165</sup>

89. During the last 150 years at least, a considerable migration from rural districts to urban areas has taken place in all European countries. The movement assumed importance at different times in various countries depending upon their stage of industrialization. In England, the movement was already pronounced in the early decades of the nineteenth century. By 1931 only one fifth of the total population remained in rural areas. The possibilities for further large-scale rural-to-urban migration, therefore, did not exist, and other types of migratory movements became predominant.<sup>166</sup> Studying internal migration in England and Wales over a century, Friedlander and Roshier found distinctive patterns in two broad periods. Between 1851 and 1911, migration was building up in the industrial centres, but the period from 1911 to 1951 was marked by a trend towards

dispersal of population from these centres owing to the decline of the coal industry and the search for better living conditions.<sup>167</sup> In Germany and the Scandinavian countries, large-scale cityward movement began in the 1870s. A similar pattern holds for France and the other countries that now comprise the European Economic Community. Once the national urban economies were able to absorb most of the surplus rural population in these countries, emigration overseas lost much of its previous importance.<sup>168</sup>

90. Beijer reviewed the literature on internal migration from rural to urban areas in twelve countries of Western Europe in the period 1945 to 1961 and found out-migration from backward rural districts in every case. The volume was small in Sweden where such districts are very few and sparsely populated. In Belgium, Luxembourg, Switzerland, the Netherlands and Denmark, an influx of foreign workers was needed to supplement the national drift of labour surplus from the countryside because the national rural population was already relatively small. Although such rural districts were more numerous in Austria, the Federal Republic of Germany and France, the outflow from them to urban industries also had to be supplemented by an influx of foreign manpower. In Norway and Finland, the volume of rural emigration roughly matched the expanding demand for urban manpower. In Italy, finally, the surplus manpower from rural backward regions reached such proportions that hundreds of thousands of these persons engaged themselves for work in Switzerland, France and the Federal Republic of Germany.<sup>169</sup>

91. In most countries of the European Economic Community, rural out-migration around 1960 was being matched by either declining or stable population in the cores of the large urban municipalities. In Belgium, the Federal Republic of Germany, France and the Netherlands, the urban and suburban fringes, special residential communities and, in some cases, industrialized rural localities were the principal net gainers through migration. In Italy, on the other hand, the prevailing rural-urban migration was superimposed upon the regional emigration from southern, middle and eastern north Italy mainly to the Roman agglomeration and to the Turin-Milan-Genoa industrial triangle which has become a major

<sup>167</sup> Friedlander and Roshier, "A study of internal migration . . ." (1966), pp. 265-266. Thomas found, however, that the outflow from the areas containing basic industries was stemmed in the post-war period when Britain had to greatly increase her volume of exports. See his "The changing pattern of internal migration . . ." (1955), p. 662.

centre of attraction since the decrease in overseas emigration earlier in the present century.<sup>170</sup>

92. In Japan, internal migration has involved principally an inflow of population into the most highly industrialized areas. The seven prefectures comprising these areas show an almost constant net inflow of population according to censuses taken between 1920 and 1960. In almost all the remaining thirty-nine prefectures there has been a net out-migration.<sup>171</sup> During the period from 1955 to 1960, twenty-six out of forty-six prefectures underwent absolute population decreases as a result of a net out-migration in excess of natural increase.<sup>172</sup> The census returns for 1965 showed a continuation of the trend towards concentration of population in metropolitan areas. Between 1960 and 1964, nearly two thirds of the total gross migration across prefectural boundaries consisted of migration into the Tokyo, Osaka and Nagoya metropolitan areas; migration from metropolitan to non-metropolitan areas, as well as between non-metropolitan areas, accounted for the remainder.<sup>173</sup> More recently, however, in-migration to the metropolitan areas seems to be reaching a saturation point. At the same time, out-migration from metropolitan to non-metropolitan areas has been gaining some importance.<sup>174</sup> Consequently, net out-migration from those non-metropolitan areas has been shrinking substantially.<sup>175</sup>

93. Data on recent trends in internal migration are less adequate for countries in the developing regions and this deficiency is even more marked with respect to movements in the past. Ho, working with highly fragmentary sources, has described the principal interregional migrations in China up to the beginning of the second half of the present century.<sup>176</sup> Especially notable has been the movement of Chinese into Manchuria which accompanied the industrial and agricultural development of that part of China since the end of the nineteenth century.<sup>177</sup>

94. In recent decades, rural-urban internal migration has become the dominant migration form and a phenomenon of great significance in all the developing regions,

<sup>170</sup> Horstmann, "Rural-urban migration ..." (1967). See also his "Die Land/Stadt-Wanderung ..." (1966). Various studies have dealt with the regional patterns of migration within Italy, among them De Vergottini, "Migrazioni interne in Italia ..." (1969); and his "Sulla gravitazione della popolazione italiana ..." (1963); Federici, "Considerazioni sulle migrazioni interne ..." (1963); Migliorini, "Migrazioni interne e spostamenti territoriali ..." (1962).

although to a greater extent in Latin America than in the others.<sup>178</sup>

95. It has been estimated that in Latin America during the decade from 1950 to 1960 there was a net flow of approximately 14.6 million people from rural areas to towns and cities.<sup>179</sup> The magnitude of both the outflow from the countryside and the inflow into the urban areas is seen in the fact that the 14.6 million net migration represents slightly over 15 per cent and 24 per cent, respectively, of the estimated total rural and urban populations at the beginning of the decade. In Brazil alone, the net movement from country to city during the 1950s was around 7 million people, or one out of every ten persons.<sup>180</sup> According to Schultz, in Colombia more than one third of the rural population under age 40 in 1951 had migrated from these areas by 1964.<sup>181</sup> Elizaga's estimates of annual intercensal net in-migration rates into the urban areas of seven Latin American countries show that in five of these (Chile, Panama, Nicaragua, Colombia and Venezuela) "the annual rates are above 1.5 per cent", and in the other two (Costa Rica and El Salvador) the rates were only slightly below 1 per cent.<sup>182</sup>

96. Interregional migration has been of considerable importance in Brazil. Historically, the impoverished north-east has been the region of heavy out-migration. Whereas it contained 47 per cent of Brazil's population in 1872, by 1960 the figure had declined to 32 per cent.<sup>183</sup> The flow of migration from the north-east and from the States of Minas Gerais and Bahia was southward, particularly to the State of São Paulo and to Rio de Janeiro. In the 1950s the new coffee districts of Paraná, the central region where the new capital of Brasilia is located, north central Maranhão and southern Mato Grosso all gained population as a result of internal migration.<sup>184</sup> The most important migration flow in

<sup>178</sup> In Africa there is evidence, not very well documented, of a wide variety of other movements. In addition to nomadic pastoralists in some areas, there is seasonal and also short-term migration (for periods up to two years) for work in mines and in agriculture as well as in towns. Prothero, "Migration in tropical Africa" (1968), pp. 251-252. In South-East Asia, movements, sometimes of considerable proportions, to settle new lands or to exploit new resources have been reported. United Nations, *The Population of South-East Asia ...* (1958), p. 55. In Latin America generally, shifting cultivators and migrant pioneers are reported to "represent a rather small proportion of the rural population of the region". United Nations, Economic Commission for Latin America, "Rural settlement patterns and social change ..." (1965), pp. 7-8. None the less, data from Brazil's 1950 census on state of birth and state of residence indicated net migration involving a rural exodus to new areas of land settlement. Diégues, "Internal migration in Brazil" (1967).

Mexico has been that towards the Federal District, that is to say, Mexico City. Another area of substantial immigration is the State of Baja California Norte where a highly mechanized intensive agriculture has been developed, its produce destined in part for export to the United States.<sup>185</sup>

97. It has generally been considered that migration rates in India are low in comparison with those of most Western European countries and the United States. This was Davis's finding based on an analysis of place-of-birth statistics from the 1931 census,<sup>186</sup> and it is, on the whole, supported by Zachariah's comprehensive study of interstate migration in India between 1901 and 1931. The principal areas which gained population through migration during this period were the States of Assam and Bengal in the east and Bombay, Mysore and Travancore-Cochin in the south-west.<sup>187</sup> There were important shifts in the predominant patterns of interstate migration during the 1940s, but in the 1950s the west and east zones again registered the principal gains.<sup>188</sup>

98. When movements other than those which occur across state boundaries are considered, the volume of migration in India appears much higher. Studying lifetime migration streams based on 1961 census results, Bose showed that while only about 3 per cent of the population were enumerated in a state other than the one in which they were born, about 30 per cent were enumerated in a place different from that of their birth. Short-distance migration, a large part of it consisting of marriage migration of women, is the predominant type of internal migration in India; moreover, most migration was shown to take place from rural to rural areas. Only among interstate male migrants did the volume of rural-to-urban migration exceed that which occurred among rural places.<sup>189</sup> Kumar's analysis of interstate migration streams during 1951-1961 revealed that the rural-to-urban component was in most cases only 30-35 per cent of the total.<sup>190</sup>

99. If the absorptive capacity of the urban population is taken into consideration, the volume of rural-to-urban migration in India looms larger. Bogue and Zachariah noted that the estimated net rural-to-urban migration of somewhat under 9 million in India during 1941 to 1951 is equivalent to a net out-migration of only 3 per cent of the 1941 rural population, but to "a rate of net in-migration to cities equivalent to 20 per cent of the 1941 urban population". Their analysis of the characteristics

of rural-to-urban migration during this period indicated it to be a widespread phenomenon which had already lost its "pioneering" characteristics; with migration channels firmly established, the nation then seemed "all set to enter a phase of unprecedented urbanization".<sup>191</sup> However, it has been estimated that net rural-urban migration during 1951-1961 amounted to only 5.2 million, a considerable drop from the volume of the previous decade.<sup>192</sup> While this apparent slowing of the pace of urbanization has not yet been adequately explained, it has been suggested that the more rapid rate of natural increase in urban areas in the 1950s, as compared with earlier periods—owing to falling mortality—may have reduced the scope for rural-to-urban migration in the absence of a sufficient expansion of urban employment opportunities.<sup>193</sup>

100. There is evidence that the phenomenon of return migration has reached substantial proportions in India, being fostered by the close ties which the urban migrant typically retains with his village of origin. This rapid turnover migration deprives India's cities of, in Mitra's words, "a true industrial proletariat who have staked their lives in the city and severed their roots in the village".<sup>194</sup>

101. Relative to the size of their populations, the volume of rural-to-urban migration appears also to be small in Ceylon and Pakistan. Trends in the urban population at different census dates suggest an acceleration in the rate of rural-to-urban migration in Pakistan during 1951-1961, while in Ceylon there seems to have been a slight reduction in the tempo of urban growth.<sup>195</sup> While much attention has been given in Indonesia to the possibilities of encouraging migration from densely populated Java to the outer islands, actual movements have been rather modest in volume, amounting to about 7 per cent of Java's annual population increase in the period before the Second World War and to only about 3 per cent in the peak post-war years.<sup>196</sup> In the Philippines according to one study, aside from the migration to metropolitan Manila, rural-urban migration during the 1950s lagged behind expectations, while movements of agricultural population to frontier lands, particularly to Mindanao, were impressive.<sup>197</sup>

102. The description of migratory movements in Africa is complicated by "the heterogeneity of its patterns which vary in relative importance between different

<sup>190</sup> Kumar, "The pattern of internal migration ..." (1967), particularly p. 628.

regions and in the same region at different times".<sup>198</sup> Most studies that have been made are monographic in nature and too circumscribed to allow ready generalizations.<sup>199</sup> One study of interprovincial migration in Kenya, using 1962 census data on province of birth and of residence, found the movements to be not only from rural to urban areas but also from the less developed to the more developed parts of rural Kenya. "The demand for labour in the modern farms that developed ..." and "... the urbanization associated with this economic revolution tended to intensify the attraction of these areas ...".<sup>200</sup> Another study, based on sample survey data, of migration into Lagos Federal Territory, the capital of Nigeria, revealed that over 80 per cent of the heads of all households were migrants although only 51 per cent of all household members were migrants.<sup>201</sup>

103. Prothero, in a broad and admittedly qualitative sketch of the various types of population movements in Tropical Africa, found movements associated with rural-urban migration to be an important feature in the mobility that has developed since the countries became independent. While people have been moving at increasing rates from rural areas to the rapidly expanding urban areas, the over-all proportion of urban population is still low. Considerable regional variations are noted.<sup>202</sup> In Ghana, Caldwell found that while rural-to-urban migration seems to have been a feature of urban growth for at least half a century, it had greatly accelerated in the 1960s. Moreover, long-term rural-to-urban migration—in which family members accompany or follow the migrant—was rising in importance relative to seasonal migration to the towns of individuals who spend part of the year working in agriculture.<sup>203</sup>

#### (b) Migration differentials

104. In the study of differential migration, migrants are usually compared with persons remaining at the place of origin or with persons native to or living in the place of destination; occasionally, however, they are compared with all non-migrants.<sup>204</sup>

105. Information on migration differentials is of interest for various reasons and research on the subject reflects this diversity of objectives. The characteristics that are studied and the base population with which they are compared often vary depending on the objectives under study. Some studies, for example, are concerned

with the consequences of migration for the population at the place of origin or at the place of destination.<sup>205</sup> Another group of studies is concerned with problems relating to the adjustment and assimilation of migrants at their place of destination.<sup>206</sup> Other scholars, interested in the migration process itself, have either been searching for universally valid differentials<sup>207</sup> or, at least, to "develop principles of selectivity" relating certain types of selectivity to major types of migration.<sup>208</sup> A variant of this approach is found in a theory once widely held that migration is positively selective with respect to personal qualities that are "based at least partly on hereditary predisposition".<sup>209</sup> Differential migration represents for others a quantitative approach either towards the formulation of migration theory or at least towards an understanding of the factors affecting migration.<sup>210</sup> Nevertheless, the majority of migration studies are purely descriptive: they attempt mainly to measure the volume of migration and to identify the migrants according to those characteristics for which information is readily available; for reasons of convenience the comparison, if any, is usually made with the population at the place of destination.

106. Owing to these different purposes in measuring migration differentials, the findings that are reported in the literature are lacking in comparability. Perhaps, for this reason, no comprehensive effort has been made recently<sup>211</sup> to review systematically the thousands of studies with data on migration differentials in order to generalize about each differential characteristic under varying conditions—geographic, historical, cultural and

<sup>205</sup> In the former case, the place of origin provides the base population; in the latter case, the place of destination. Demographers are often interested in sex and age differentials in order to study the effect of migration on the sex-age structure at the place of origin, the place of destination, or both; the significance of changes in sex-age structure for crude death rates, birth rates, economic activity rates, school attendance rates etc., has been noted in other chapters. Various other characteristics of migrants, such as marital status, level of education, level of fertility, occupation and ethnic composition, are of interest to different specialists.

<sup>206</sup> See, for example, Germani, "Migration and acculturation" (1964), pp. 163-166, 176 ff.

<sup>207</sup> In this class falls one of Ravenstein's laws (see section D) that "females appear to dominate among short-journey migrants". Ravenstein, "The laws of migration" (1885, 1889). Among the series of hypotheses about the characteristics of migrants formulated by Lee is one that migrants tend to be bimodally selected with respect to qualifications (some ranking high and others low in terms of occupational or educational skills). Lee, "A theory of migration" (1966), pp. 48, 56-57.

<sup>208</sup> Bogue, "Internal migration" (1959), p. 505.

<sup>209</sup> Hofstee, *Some Remarks on Selective Migration* (1952), pp. 1-2. Hofstee reviews and evaluates many of the studies done on selective migration prior to the Second World War in the Netherlands and in the United States. The principal characteristics used in these studies were brain measurements, intelligence tests and social achievements. A summary of some of his findings is given later in this section.

<sup>210</sup> According to this view, migration is part of the process of adjustment to basic social and economic changes that are taking place. The migrants are the persons most exposed to the effect of these changes and their differential characteristics should reflect this differential exposure. Bogue, "Internal migration" (1959), p. 505.

<sup>211</sup> Not since the 1938 study by Thomas, ed., *Research Memorandum on Migration Differentials* (1938).

<sup>198</sup> Lorimer, Brass and Van de Walle, "Demography" (1965), p. 297.

<sup>199</sup> Brass *et al.*, *The Demography of Tropical Africa* (1968), p. 8.

<sup>200</sup> Ominde, "Some aspects of population ..." (1968).

<sup>201</sup> Ejiogu, "African rural-urban migrants ..." (1968).

<sup>202</sup> Prothero, "Migration in tropical Africa" (1968), pp. 250-252. See also his "Socio-economic aspects of rural/urban migration in Africa ..." (1965).

<sup>203</sup> Caldwell, *African Rural-Urban Migration ...* (1969), pp. 201-203, 210.

<sup>204</sup> Often the terms "selective migration" and "differential migration" are used interchangeably. See, for example, Bogue, "Internal migration" (1959), p. 497. More frequently, however, the term selective migration is reserved for comparisons with non-migrants at the place of origin from among whom the migrants were "selected".

other. Indeed, it has also been suggested that selectivity is in part a function of the phase of migratory movements. According to this view, migration is more highly selective at the initial or pioneer phase of a movement and becomes more representative of the general population at the place of origin when the migration becomes a mass movement.<sup>212</sup>

#### (i) Age

107. Without much doubt, the most universally valid of all migration differentials is the age differential, and there are few exceptions to the rule that migration is selective of persons in young, adult working ages.<sup>213</sup> Migrants are generally concentrated in an age range from 15 or 20 to about 30 or 35 years. In the Soviet Union, the ages of particular concentration during the period 1939 to 1958 were those between 18 and 35,<sup>214</sup> and in the United States from 1964 to 1965, the peak was between the ages 20 and 29.<sup>215</sup> In Hungary and the German Democratic Republic, the modal internal migration age range in 1962 was 20 to 24 and 18 to 20 respectively.<sup>216</sup> In Japan, two thirds of the inter-prefecture migrants during the year prior to the 1960 census were in the ages 15 to 29.<sup>217</sup> In the United Arab Republic, mobility reaches a peak at ages 20-24, remains high at ages 25-29

<sup>212</sup> The distinction between the pioneer and mass or social phases of a migratory movement is found in Mortara, "Factors affecting rural-urban migration ..." (1967), p. 512; and Petersen, *Population* (1961), p. 608. Browning and Feindt have applied it specifically to differential migration in their study of migrants into Monterrey, Mexico, and found "that migrants have become increasingly less selective over time". See their "Selectivity of migrants to a metropolis ..." (1969), p. 355. Somewhat similarly, Germani has suggested that the rate of out-migration from rural areas will be inversely associated with selectivity and directly related with the degree of disintegration of the traditional order; a high rate of out-migration, for instance, would indicate advanced disintegration and the selectivity of the migration would then be rather low. Germani, "Migration and acculturation" (1961), pp. 169-170.

<sup>213</sup> Tabah and Cosio, "Mesure de la migration interne ..." (1970), p. 339; Kuroda, "Internal migration ..." (1967), p. 507; Bogue, "Internal migration" (1959), p. 504. But there are some types of migration where this is not the case. In the United States, for instance, there is a migration of retired aged persons to climatically favoured areas, such as Florida or Arizona. A comparison of age structures in central cities with those in suburban areas which have been annexed to them indicates that city-to-suburb migration draws largely on mature adults and their children, as can be inferred from data in Miller and Varon, *Population in 1960* ... (1961).

<sup>214</sup> Daragan, "Economic development and internal migration" (1967), p. 491.

<sup>215</sup> Bogue, *Principles of Demography* (1969), p. 761. During the decades from 1870 to 1950, around 45 or 50 per cent of interstate migrants were between the ages 20 to 34 (age at end of decade). Thomas, "Internal migration in the United States ..." (1967), p. 535.

<sup>216</sup> Thirring, "Internal migration in Hungary ..." (1967), p. 531. In a study of migrants to German cities in the 1930s, it was found that the highest migration rates for males occurred between ages 20 and 25 and for females at about age 20. Heberle and Meyer, *Die Grossstädte* ... (1937), pp. 22-25.

<sup>217</sup> Ueda, "Internal migration affecting age composition ..." (1967), p. 538. A considerable amount of migration of young persons in Japan results from the fact that most colleges and universities are located in metropolitan centres, and students who migrate there frequently remain after their graduation. See, for example, Ueda, "Kokunai jinko ido ni kansuru ..." (1967), p. 76.

and then falls sharply.<sup>218</sup> Among migrants into Bombay, India, during the intercensal period 1951-1961, about 43 per cent were between the ages 20 and 35.<sup>219</sup> A sample survey in Lagos, Nigeria, showed in-migrants to be especially concentrated at the ages 15 to 34,<sup>220</sup> and in Ghana it was found that initial migrations to the towns are generally made between 15 and 25 years of age.<sup>221</sup> Female in-migration rates in Guayaquil, Ecuador, Panama City, Panama and Greater Santiago, Chile, were often higher at the ages 10 to 14 than at 30 to 34 years of age.<sup>222</sup> In the urban areas of Mexico, migration rates were found to be highest for males at ages 20 to 29, and for females at ages 15 to 29.<sup>223</sup> According to Tabah and Cosio, in France, the United States and other industrialized countries, the migration rate is also relatively high at very young ages; in less developed countries this phenomenon is much less apparent, if at all.<sup>224</sup> Despite the well-nigh universal concentration of migrants in the young working ages there is some evidence that in countries where retirement from work is associated with a change of residence, specific streams of certain types of migration may be heavily weighted with persons in the older ages.<sup>225</sup>

#### (ii) Sex

108. The validity of Ravenstein's generalization that "females appear to dominate among short-journey migrants"<sup>226</sup> appears to depend in part upon how the notion "short-journey" is defined. Some scholars have reformulated the differential to state that females preponderate in well-established, secure migratory movements and males in those streams that have a pioneering or innovating character.<sup>227</sup> This formulation is more in agreement with data showing that in most of Asia and Africa (where urbanization is still in an early stage), urban migration is primarily a movement of males, whereas generally in Latin America, Europe, North America and Oceania (except in cities which are centres of heavy industry), a heavier migration of women to cities is found.<sup>228</sup> The phenomenon is evidently complex

and related to differential employment opportunities by sex and a number of other considerations as well.<sup>229</sup> In the Soviet Union, the migrant population includes somewhat fewer women than men in the country as a whole, although the ratio varies in different economic and administrative regions.<sup>230</sup> In Poland, "men constitute the major portion of emigration from villages to towns".<sup>231</sup> In the United States, male interstate migration rates used to exceed those of females, but the two sets of rates had converged by 1950.<sup>232</sup> Trends in Canada between 1901 and 1961 also show a narrowing differential over time, and the ratio of males to females among migrants was positively associated with the distance of the move.<sup>233</sup> In the Netherlands and in the Federal Republic of Germany, females are reported as predominating in migration out of rural municipalities and males in migration out of large towns.<sup>234</sup> In France, sex ratios by age from the 1946 census for rural communes and for cities of 100,000 or more population clearly show that rural-urban migration is selective of females.<sup>235</sup> In Latin America, one study showed net in-migration rates in urban areas to be higher for females in seven countries;<sup>236</sup> another study, finding a higher proportion of women of reproductive age in urban areas than in rural areas in all Latin American censuses since the Second World War, attributed this to the predominance of females in rural-to-urban migration.<sup>237</sup> Males predominated in migration into Lagos, Nigeria.<sup>238</sup> In India for the period 1941 to 1951, Bogue and Zachariah report the surprising finding that, although male in-migrants exceeded females in the cities of Bombay, Madras, Delhi and Calcutta, the difference was substantial only in Bombay.<sup>239</sup> How this finding can be reconciled with the considerably higher urban than rural sex ratio in India<sup>240</sup> is not clear. In summary, it may be said that varying patterns of sex-selective migration are found; these variations appear to be associated with economic aspects of the social structure in conjunction with the socio-cultural position of women in society.

### (iii) Marital status

109. Much less information is available on migration differentials by marital status than by sex and age, and most discussions of the former are less systematic in their coverage. A stumbling-block in this connexion is the problem of inferring marital status at the time of migration from available information on status at the time of enumeration. In the case of marriage migration, such as in India<sup>241</sup> and in pre-industrial Japan,<sup>242</sup> this distinction is not very important as long as marriage usually occurs around the time of migration. In at least some of the instances of preponderantly male migration to cities in Africa and Asia, many of the unaccompanied men are in fact married and either remit money home to their family or else return with their savings at the end of their migration period.<sup>243</sup> In Latin America a flow of young, unmarried females seeking domestic employment in the cities has been observed.<sup>244</sup> In the United States an analysis of 1960 census data disclosed, rather surprisingly, a higher proportion of migrants among married persons than among single persons.<sup>245</sup>

### (iv) Fertility

110. Two sets of considerations can affect the relation between migration and fertility. Since migration, or geographical mobility, occurs in many instances as a response to differential economic opportunities and therefore is a form of social mobility,<sup>246</sup> it might be expected that migratory streams of this kind (especially rural to urban), would be highly selective of persons of lower than average fertility at the place of origin. Secondly, however, the question is raised whether rural-to-urban migrants, taking into consideration their origin in a place where fertility is above average<sup>247</sup> and their briefer exposure to the conditions of urban life in modern industrial society,<sup>248</sup> will have higher or lower fertility than urban natives. Undoubtedly, on account of inadequate data, there has been very little research into the first point regarding the fertility selectivity of migrants with respect to place of origin. Most of the research has been on

<sup>241</sup> Bose, "Internal migration in India ..." (1967), p. 485; Davis, *The Population of India* ... (1951), pp. 111-114.

<sup>242</sup> Taeuber, *The Population of Japan* (1958), p. 139. Even in recent years persons migrating for marriage have constituted an important proportion of all migrants into large cities (about 10 per cent in Tokyo and 14 per cent in Kawasaki, according to surveys). Tokyo Metropolitan Government, *Tokyo-to Ido Jinko Tokei* ... (1963); Kuroda, "Jinko ido no doko ..." (1972), p. 5.

<sup>244</sup> United Nations, *Report on the World Social Situation* ... (1957), pp. 174-181; Elizaga, "A study of migration to Greater Santiago ..." (1966), p. 364.

<sup>245</sup> Bogue, *Principles of Demography* (1969), pp. 767-768. However, the interpretation of the data is uncertain since marital status referred to status at the end of a five-year migration period.

<sup>246</sup> See chapter IV, section D, for a discussion of social mobility as one of the factors in the transitional decline of fertility.

<sup>247</sup> See chapter IV, section F, for a discussion of urban-rural fertility differentials.

<sup>248</sup> See chapter IV, section D, for a discussion of urbanization as a factor in the transitional decline of fertility.

comparisons of migrant and native fertility at the place of destination and has been concerned principally with the United States and various countries of Latin America. The results to date are inconclusive. A study of migrants during the period 1935 to 1940 in the United States showed that the migrants, as compared with natives resident in a given region, generally had lower fertility except in the North Central States where most of the migrants had come from high-fertility areas in the South.<sup>249</sup> Separate studies by Kiser and Goldberg, using different data from the 1930s, arrived at opposite conclusions in comparing the fertility of rural and rural-farm migrants into cities with that of native urbanites. In Latin America, studies of in-migrants into Monterrey, Mexico, and into Santiago, Chile, found no significant differential fertility between migrants and native residents. On the other hand, various studies in Argentina, Brazil and Puerto Rico have found migrants to have lower fertility than non-migrants.<sup>250</sup>

#### (v) Education

111. Aside from sex and age, education is the characteristic on which information concerning differential migration is most readily available. Education is used as an index of socio-economic status and also as a measure of population quality, whether as a reflection of investment in human capital or of genetic differences. Rather diverse findings are reported in the literature. In-migrants into Bombay<sup>251</sup> and into Calcutta<sup>252</sup> in India have less education than non-migrants at the place of destination, but more education than the population of the states from which they are drawn. A similar result, comparing the educational level of in-migrants into Santiago, Chile, with people living in the rest of the country is found by Herrick who explains this on the ground that somewhat educated migrants are alert to changing employment opportunities, but originate in areas where educational opportunities are more limited.<sup>253</sup> According to the 1960 census results, migrants into the Federal District of Mexico were much inferior in education to the natives of the district.<sup>254</sup> In a survey conducted in Ghana, Caldwell compared migrants with non-migrant rural residents and found a strong positive relationship between duration of schooling and the propensity to migrate from rural areas to the towns.<sup>255</sup> Education also appeared to be an important factor in mobility in Canada and the United Kingdom. Canadian data show that among the

25-34 years age group, persons classified as migrants during 1956-1961 had higher levels of educational attainment than did those classified as non-migrants, and this was true in urban, rural non-farm and rural farm areas.<sup>256</sup> A survey in England and Wales in 1959-1960 showed that persons with at least a grammar school education were twice as mobile as those without such an education.<sup>257</sup> On the other hand, net out-migrants in the period 1940 to 1950 from rural farm areas in the United States as a whole and in North Carolina tend towards the two extremes, with net migration highest for both high and low educational levels.<sup>258</sup> In a critical review of many migration studies in the Netherlands and in the United States, Hofstee found that migration as such is not necessarily selective with respect to intelligence and education. Such a selection does generally characterize rural-urban migration, but not migration within the countryside. Hofstee notes exceptions to this principle of selection among migrants to cities also and concludes that migration is determined primarily by the spatial distribution of opportunities. The character of migration to a certain place is seen as depending on the specific opportunities it offers, whether, for example, labour force demand is principally for highly qualified personnel or for unskilled labourers.<sup>259</sup>

#### C. The distribution and growth of urban and rural population

112. Human settlement has until recently been mostly rural. It is true that a number of famous cities existed even in ancient times,<sup>260</sup> and have been of decisive significance in the innovation of human culture and civilization. But, as places of human residence and employment, cities did not absorb a large proportion of the population until the nineteenth century, and even then only in selected areas of the world. Thus, the division of human population into categories of urban and rural residence did not acquire demographic significance until modern times.

113. As discussed below, it is estimated that not more than 3 per cent of the world's population could have been considered urban in 1800, and it is uncertain whether there was even one city having a million inhabitants at that time. The emergence of cities as quantitatively important points of population accumulation can be regarded as a major event of the nineteenth century. Thus it was that Adna Weber, writing in 1899 concerning the growth of cities, observed in the opening sentence of his study: "That the most remarkable social phenomenon of the present century is the concentration of population in cities is a common observation . . ."<sup>261</sup>

<sup>249</sup> Kiser, "Fertility rates by residence . . ." (1959), pp. 280-281.

<sup>250</sup> For brief reviews of these and other studies on this subject, see Macisco, Bouvier and Weller, "The effect of labour force participation . . ." (1970), and Myers and Morris, "Migration and fertility in Puerto Rico" (1966), pp. 85-86. A detailed listing of bibliographic materials on the fertility-migration relationship for all regions of the world can be found in Macisco, Bouvier and Renzi, "Migration status, education and fertility . . ." (1969), pp. 183-184.

<sup>259</sup> Hofstee, *Some Remarks on Selective Migration* (1952), pp. 4-13.

<sup>260</sup> Some of these are described in chapter II, section A.

<sup>261</sup> Weber, *The Growth of Cities in the Nineteenth Century* . . . (1899; 1963 ed.), p. 1.

114. The emergence of urbanized nations in which a clear majority of the population resides in cities will undoubtedly be recognized in future history as one of the most remarkable events of the present century. At the beginning of this century only one nation, Great Britain, could be regarded as an urbanized society in the sense that more than one half of its inhabitants resided in cities.<sup>262</sup> By mid-century there were at least eighteen such nations, and by 1965 there were at least thirty.<sup>263</sup> But the majority of nations are still predominantly rural.

115. The criteria by which urban and rural localities are distinguished vary from country to country and in the course of time. Traditionally, rural residence has been associated with agricultural employment. Although rural areas may contain relatively concentrated settlement patterns in some countries, it has frequently been insisted that such population clusters must not be regarded as urban if the residents are primarily engaged in agriculture. Thus, Weber wrote that "A German *Dorf* or village containing, say 300 peasants, is just as properly called rural as an American township containing 300 farmers living half a mile apart".<sup>264</sup> In India today some localities with more than 5,000 inhabitants may appear as rural "over-grown villages".<sup>265</sup> According to the 1961 urban definition used in the Census of India, places of 5,000 or more inhabitants may be excluded from the urban category if more than one fourth of the inhabitants are engaged in agriculture.<sup>266</sup>

116. The notion that type of employment (agricultural versus non-agricultural) is a key distinction between rural and urban localities is recognized in urban definitions of a number of countries. More typically, the distinction between urban and rural localities rests on a quantitative criterion of number of inhabitants. In many countries, the cutting point between urban and rural localities may lie between 2,000 and 5,000 inhabitants, though there are also many exceptions. In Denmark, for example, all places with 200 or more inhabitants are classified as urban.<sup>267</sup> In some countries, the distinction between urban and rural localities rests on a mixture of the size of place and economic activity criteria. In a 1955-1957 survey in the Democratic Republic of the Congo, for example, urban localities are defined as follows: "Agglomerations of 2,000 or more inhabitants where the predominant economic activity is of a non-agricultural type and mixed agglomerations ... which are urban because of their type of economic activity, but rural in

size".<sup>268</sup> Still other criteria such as density, administrative status or the presence of selected services or facilities are mentioned in other urban definitions.<sup>269</sup>

# 1. THE DISTRIBUTION OF URBAN AND RURAL POPULATION IN 1965

117. The "urban" and "rural" population estimates presented in tables VI.2 and VI.3 were compiled by the United Nations from national sources, using the official definition of "urban" population in each country.<sup>270</sup> Although the urban definitions vary greatly from one country to another, it is believed that often the differences in definition may reflect differences in the characteristic features of urban and rural settlement considered most relevant in individual countries.

118. From table VI.2 it can be seen that a clear majority of the population in the presently developing regions resides in rural areas, while a clear majority of the population in the presently more developed regions resides in urban areas. One evident conclusion from such statistics is that urbanization is somehow an important aspect of economic development. More precisely, it is the shift in employment, from almost exclusively agricultural to predominantly non-agricultural activities, that constitutes development of productive capacity. In such highly urbanized countries as the United Kingdom and the United States, the proportion of the economically active population engaged in agriculture had fallen to 5 and 8 per cent, respectively, according to censuses taken around 1960.<sup>271</sup>

119. There is no exact correspondence between the shift of labour force from agricultural to industrial pursuits and the shift of population residence from rural to urban areas. In developing countries, especially, many migrants who abandon agricultural pursuits and move to the cities may find little opportunity to obtain industrial employment there. While many of them accumulate in service activities characterized by much underemployment

<sup>268</sup> United Nations, *Growth of the World's Urban ...* (1969), p. 84.

<sup>269</sup> Problems of international comparability with respect to urban definitions are discussed in *ibid.*, pp. 7-10. It has sometimes been argued that agglomerations of population should be classified as urban on quantitative demographic criteria alone, without regard to urban features or occupations, since the same qualitative features are not applicable to all cities at all times. Thus, Eldridge observes that "Ancient Rome was none the less a city in spite of the fact that it was without electricity. Modern Calcutta is none the less a city in spite of the fact that a large number of its people live in dwellings that do not have running water. The rural agglomerations of Italy are none the less agglomerations, though the majority of their inhabitants are in agricultural occupations." See her "Urban theory and concepts ..." (1955), p. 585.

<sup>270</sup> United Nations, *Monthly Bulletin of Statistics, November 1971* (1971), table B.I. Another set of estimates of urban and rural population for individual countries in 1950, 1960 and 1970 has been prepared independently at the Institute of International Studies, University of California, under the direction of Kingsley Davis. See Davis, *World Urbanization 1950-1970*, vol. 1 ... (1969), pp. 54-82. In addition to urban and rural totals, this source provides totals by size of city for each country (pp. 83-111) as well as population estimates for individual cities of 100,000 or more inhabitants (pp. 161-233).

<sup>271</sup> See chapter IX, section D.

<sup>262</sup> Davis, "The origin and growth of urbanization ..." (1955), p. 433.

<sup>263</sup> Estimates of the United Nations. Percentages of urban population in individual countries for 1965 appear in United Nations, *Monthly Bulletin of Statistics, November 1971* (1971), table B.II.

<sup>a</sup> Urban population defined as that of "densely inhabited districts", according to the census.

and low productivity, others remain unemployed.<sup>272</sup> Moreover, in later stages of development the rural areas themselves become less agricultural. A larger proportion of the rural population becomes engaged in commerce and local industries related to agriculture rather than farming as such. In addition, some persons employed in cities prefer to maintain rural residences once suitable transportation facilities can be provided for commuters. There is also a tendency for certain space-consuming urban employment to be exported to rural locations.

120. By 1965, approximately 35 per cent of the world's 3,300 million inhabitants resided in urban areas. Two major areas—Africa and Asia—are only about 20 per cent urban, while all of the other major areas are more than half urban.

121. Although the level of urbanization in Asia is low, its share of the world's urban population is nevertheless higher than that of any other area because its total population is so large. Asia alone claims slightly more than half of the total world population; its 411 million urban inhabitants constitute over one third of the world's urban population; and its 1,422 million rural inhabitants are roughly two thirds of the world's rural population (see table VI.3). It is significant to note in this connexion that Asia's two most populous countries, China and India, contain between them roughly two thirds of its total population, its urban population, and its rural population as well. Moreover, each of these two nations individually contains more total population and more rural population than any of the major areas, outside of Asia.

<sup>272</sup> *Ibid.*

TABLE VI.3. PERCENTAGE DISTRIBUTION OF THE WORLD'S URBAN AND RURAL POPULATION AMONG MAJOR AREAS AND REGIONS

Major areas and regions	Urban population	Rural population
World total	100.0	100.0
Developing regions	45.4	81.1
More developed regions	54.6	18.9
Africa	5.2	11.4
Western Africa	1.4	3.5
Eastern Africa	0.6	3.7
Middle Africa	0.3	1.3
Northern Africa	2.1	2.3
Southern Africa	0.8	0.5
Asia (excluding the USSR)	35.4	66.8
East Asia	19.0	29.7
Mainland region	13.1	25.7
Japan <sup>a</sup>	4.0	2.4
Other East Asia	1.8	1.5
South Asia	16.4	37.2
Middle South Asia	10.2	25.7
South-East Asia	4.1	9.4
South-West Asia	2.0	2.1
Europe (excluding the USSR)	23.4	8.1
Western Europe	8.9	1.9
Southern Europe	5.1	3.0
Eastern Europe	4.4	2.3
Northern Europe	5.1	0.9
Latin America	11.1	5.5
Tropical South America	5.7	3.0
Middle America (mainland)	2.3	1.4
Temperate South America	2.2	0.5
Caribbean	0.8	0.7
Northern America	13.3	2.8
Oceania	1.0	0.3
Australia and New Zealand	1.0	0.1
Melanesia	0.0	0.1
Polynesia and Micronesia	0.0	0.0
USSR	10.6	5.0

SOURCE: computed from data in table VI.2.

<sup>a</sup> Urban population defined as that of "densely inhabited districts", according to the census.

122. The level of urbanization in both China and India is roughly the same: China is estimated to be about 21 per cent urban and India about 19 per cent. The remaining third of Asia's population is distributed over a large number of countries. While the average level of urbanization in these countries is not far from that of China or India, still there is some range of variation. For example, Indonesia is about 16 per cent urban; Thailand 14 per cent; Pakistan 13 per cent; and Afghanistan only 7 per cent. A number of other countries of the group, many of them in South-West Asia, are well over 30 per cent urban (Iraq is 44 per cent urban; Syria 40 per cent; Lebanon 36 per cent; Jordan 44 per cent; and Israel is 78 per cent urban).<sup>273</sup>

123. It is interesting to note that Asia's presently large share of the world's urban population (roughly

one third in 1965) is actually less than it was in historic times. Murphey has observed that "Until about 1750 or 1800, it seems likely that Asia . . . contained more cities and more city-dwellers than the rest of the world combined".<sup>274</sup> He estimates that if current rates of population growth and urbanization continue, Asia may regain her earlier share of the world's urban population by the end of the present century. Because Asia in 1965 begins with a comparatively low level of urbanization, there is enormous potential for expansion of Asian cities during the present century. In many other areas of the world where the level of urbanization is already high, the urban growth rates may taper off as the rural population becomes reduced and no longer provides so many migrants.

124. Africa, with the largest territory of any of the major areas, is second to Asia in its share of the world's rural population (about 11 per cent), but the absolute size of Asia's rural population (1,422 million) is more than five and one-half times that of Africa (243 million). The size of Africa's urban population is not large—only 60 million or 5 per cent of the world's total urban population. For Africa as a whole, the percentage urban is roughly 20 per cent. In certain countries of Africa, especially in Eastern Africa, the percentage is extremely low (for example, only 6-9 per cent in Ethiopia, Kenya, Uganda and the United Republic of Tanzania). A few African countries are as much as 30 per cent or more urban: Morocco (30 per cent), Algeria (38 per cent), United Arab Republic (40 per cent), and South Africa (49 per cent).

125. Latin America and the Soviet Union stand at intermediate levels of urbanization. In both areas slightly over half of the population is urban. The two areas occupy almost the same amount of land surface and contain populations of approximately the same size. Their urban and rural populations are also quantitatively similar: each contains approximately 11 per cent of the world's urban population and approximately 5 to 6 per cent of its rural population.

126. Half of Latin America's population is contained in its two most populous countries—Brazil and Mexico. Brazil is 51 per cent urban and Mexico is 53 per cent urban. Argentina, the third largest country, represents a major departure from the average pattern of the area, being fully three-fourths urban. Uruguay and Chile are also highly urbanized, with about 75 and 69 per cent urban, respectively.

127. Within the Soviet Union, the distribution of population and cities is somewhat uneven. In 1962, over two-thirds of the urban population was clustered in the European portion of the country which occupies a relatively small part of the territory of the USSR. The remainder of the urban population was located in the eastern areas which include a much larger territory (the Urals, western Siberia, eastern Siberia, the far east, central Asia and Kazakhstan). Interestingly, the percentage urban is roughly the same in both the western and the eastern areas.<sup>275</sup>

<sup>273</sup> United Nations, *Monthly Bulletin of Statistics*, November 1971 (1971), table B.II. The figures quoted are those for 1965.

<sup>274</sup> Murphey, "Urbanization in Asia" (1969), p. 58.

<sup>275</sup> Kovalev *et al.*, eds., *Goroda Mira* (1965), pp. 15-17.

128. Europe has a clear majority of urban population—61 per cent. Although its land surface is small when compared with the major areas discussed thus far, it is second only to Asia with respect to total population and urban population. The urban population of Europe is as large as the combined urban populations of Latin America and the Soviet Union; and four and one-half times as large as the urban population of Africa.

129. Most of the countries of Europe have a rather significantly higher or lower level of urbanization than the average for Europe as a whole. On the one hand, countries of southern and eastern Europe have typically about one half of their populations in urban areas. On the other hand, the average level of urbanization in the countries of northern and western Europe is about three-quarters.

130. The remaining areas comprise some of the world's most highly urbanized nations: Australia (83 per cent urban); New Zealand (77 per cent urban); the United States (72 per cent urban) and Canada (73 per cent urban). The urbanization level is also high in Japan, its percentage depending on how "urban" localities are defined.

131. The pattern of population settlement within the presently most urbanized areas is extremely uneven. In 1965 almost half (48 per cent) of Japan's total population resided within the "Tokaido megalopolis" which is a coalescence of Japan's three largest metropolitan areas (Tokyo, Osaka and Nagoya) containing only 19 per cent of the land area in Japan.<sup>276</sup> In 1965, the Tokaido megalopolis contained close to 50 million inhabitants.<sup>277</sup> In 1960, 100 million inhabitants of the United States—56 per cent of the nation—were concentrated in eleven urban regions containing only 7 per cent of the land area in the United States.<sup>278</sup> The largest megalopolis in the United States—the Atlantic Seaboard area which extends from Boston through New York, Philadelphia, and Baltimore to Washington—probably contained roughly 40 million inhabitants at the same date.<sup>279</sup>

## 2. THE GROWTH OF URBAN AND RURAL POPULATION IN MODERN TIMES

132. Recorded history begins with the rise of cities and most of history has been shaped by events occurring in cities. Nevertheless, it remains certain that until modern times urban localities contained only a small minority of the world's population.<sup>280</sup> There were obvious limitations

<sup>276</sup> Kono, "Recent trends of internal migration ..." (1968), p. 586.

<sup>277</sup> The demography of the megalopolis in Japan has been analysed by Tachi, "Nihon ni okeru megalopolis ..." (1965).

<sup>278</sup> Pickard, "Future growth of major U.S. urban regions" (1967), pp. 2-10.

<sup>279</sup> The term "megalopolis" was popularized by Gottmann. See his *Megalopolis: the Urbanized Northeastern Seaboard ...* (1961). Gottmann argues that the megalopolis of the United States represents a "contemporary projection" of future urbanization trends in other industrialized countries. See his "Mégalopolis: région-laboratoire de l'urbanisation moderne" (1962).

<sup>280</sup> According to one author, even in well-organized empires the urban population probably never exceeded 5 per cent of the total. Russell, "Late ancient and medieval population" (1958).

to city growth since urban populations depended on the production of a sizeable agricultural surplus, its efficient transportation, and those military, sacerdotal or administrative arrangements without which the regular distribution of the necessities of life could not have been ensured for the urban inhabitants.<sup>281</sup> Since wealth accumulated in cities, they were often under threat of attack and had to be fortified with walls and gates and their legal residents had to be distinguished by special rights and obligations. The development of an enriched urbane way of life required increasing expenditures, mostly at the expense of the rural population. Exhaustive taxation of peasants and rising administrative costs of increasingly parasitic cities eventually sapped their foundations and rendered them prone to military conquest causing them to decline and sometimes to vanish altogether.

133. In extensive empires of western antiquity, as also in various periods in China, India and Persia, principal cities attained several hundred thousand inhabitants, and sometimes perhaps even one million, though the estimates are very debatable.<sup>282</sup> Disintegration of the western part of the Roman Empire brought in its wake large losses in urban population. Even late in the Middle Ages, European cities, though numerous, were much smaller, typically in the tens of thousands, than had been those of antiquity. Imperial disorganization in China, India, south-east Asia and Persia may at times have had similar effects. It is certain that in the Sung period China was considerably more urbanized than Europe, and it is possible that at the end of the eighteenth or at the beginning of the nineteenth century the world's biggest city was Edo (now Tokyo) in Japan.<sup>283</sup>

134. It is thus quite likely that even up to the eighteenth century Europe was at a distinctly lower level of urbanization than were certain parts of Asia. Despite these smaller beginnings, the modern cycle of massive urbanization has originated in Europe, in a development that can be traced back to the rise of small, but numerous, towns in the later Middle Ages. The previously narrow limits on urban growth were lifted, leading eventually to cities of historically unsurpassed size, and to urbanization levels comprising majorities of the population in an increasing number of nations. One is led to question why such massive urban developments failed to occur at earlier times elsewhere. The answer, perhaps, may have to be sought in terms of the cities' principal functions, many of which, in history, were parasitic, preying upon the resources of the agrarian economy while offering little in return. In Europe, since the later Middle Ages, the function of

<sup>281</sup> See also the discussion of factors affecting the growth of cities in section D.

<sup>282</sup> Among possible estimates are the following: 350,000 inhabitants in Babylon in the sixth century B.C.; 500,000 in Pataliputra (now Patna, in India) in the fourth century B.C.; 700,000 in Alexandria (Egypt) in the first century B.C.; 1,100,000 in Rome in the second century of the present era; 750,000 in Baghdad in the ninth century; and 1,500,000 in Angkor (Khmer Empire) in the tenth or eleventh century. Schneider, *Babylon is Everywhere ...* (1963), pp. 138, 301.

<sup>283</sup> See the further discussion below.

TABLE VI.4. TRENDS IN URBAN POPULATION, 1800-1950

Year	Places with 5,000 or more inhabitants		Places with 20,000 or more inhabitants		Places with 100,000 or more inhabitants

cities became predominantly commercial,<sup>284</sup> resulting in a wider distribution of benefits including gains in the rural sectors leading to increased agricultural productivity and also a broadened basis of purchasing power, hence an ever-growing potential for eventual urban growth.<sup>285</sup> The rise of competing nation states in Europe consolidated wider markets and facilitated the equipment of fleets, conquest of overseas colonies, and emergence of the mercantilist phase of modern imperialism. This added further impetus to city growth, especially sea-ports and river ports where large cargoes were warehoused, transferred from one means of transportation to another, and again redistributed. Large commercial capital was thereby generated which, in turn, provided the resources for investments in manufacturing processes as the Industrial Revolution went under way. Urban and rural developments then became mutually reinforcing, resulting in a vast transfer of labour force from agriculture to urban occupations.

135. Since definitions of urban localities vary among countries and change in the course of time, studies of time trends are usually conducted in terms of cities or towns having at least some minimal size. Davis and Hertz, for example, estimated the populations in localities of 5,000 or more inhabitants, 20,000 or more inhabitants, and 100,000 or more inhabitants at various dates between 1800 and 1950. Their estimates, which are assembled in table VI.4, indicate that unprecedented levels of urbanization emerged in the nineteenth century. The population in localities of at least 5,000 inhabitants is shown to have comprised about 3 per cent of the world's population in 1800 and about 30 per cent in 1950, the percentage more than doubling in each half century. A similar pattern of growth is seen in the estimates of population in localities of 20,000 or more inhabitants. Numbering about 22 million in 1800, or 2.4 per cent of the total population, by 1950 it had reached over 500 million, constituting about

21 per cent of the total population. During the same century and a half, the population in cities of 100,000 or more inhabitants grew from less than 16 million to over 300 million, or from less than 2 per cent to 13 per cent of the total population.

136. The acceleration in the rate of growth of the world's urban population is shown by the fact that, whereas the population living in localities of 20,000 or more inhabitants increased by nearly one and a third times between 1800 and 1850, it grew by nearly two times between 1850 and 1900 and by nearly two and a half times between 1900 and 1950.

137. Long-term trends in urban population in different regions of the world were estimated by Davis and Hertz on the basis of large-city population, namely that in cities of 100,000 or more inhabitants.<sup>286</sup> These data, presented in table VI.5, show the wide divergence of urbanization trends in different parts of the world during the nineteenth and twentieth centuries. The phase of massive urbanization attained its largest momentum first in Europe, then in areas of European settlement, and only more recently elsewhere. The large-city population of Europe increased by one and a half times between 1800 and 1850 and by nearly two and a half times between 1850 and 1900, but its growth then slackened, merely doubling in the first half of the twentieth century. While there were less than two million persons living in cities of 100,000 or more inhabitants in the Americas in 1850, this number expanded rapidly during the next century. Asia's large-city population grew very slowly during the nineteenth century, but sharply accelerated in the twentieth century; between 1900 and 1950 it increased by about four and a half times. The big-city population of Africa, which was extremely small until the twentieth century, also showed a great acceleration between 1900 and 1950. On the whole, the large-city populations of Europe and the Americas combined grew more rapidly than those of the rest of the world during the nineteenth century, but more slowly since 1900.

138. Trends in the urban population during the twentieth century have been examined in a United Nations study, which also reviewed trends in the small-town and rural population.<sup>287</sup> In this analysis, the urban population was defined as that in agglomerations of 20,000 or more inhabitants, the rural and small-town population making up the remainder. As seen in table VI.6, the agglomerated population in the world as a whole grew from an estimated 266 million in 1920 to 760 million in 1960, rising from 14 to 25 per cent of total population. The decennial figures show a marked acceleration during 1950-1960 not only in the rate of growth of the population of urban agglomerations, but also in the rate of urbanization, measured in terms of the percentage of total population

<sup>284</sup> The dominantly commercial role of European cities was stressed by Hoyt, "Forces of urban centralization . . ." (1941), pp. 843-852. As Davis put it, in other areas or at different times "the city was still attempting to supplement its economic weakness with military strength, to command its sustenance rather than to buy it honestly. In western Europe, starting at the zero point, the development of cities not only reached the stage that the ancient world had achieved but kept going after that. It kept going on the basis of improvements in agriculture and transport, the opening of new lands and new trade routes, and, above all, the rise in productive activity. . . ." Davis, "The origin and growth of urbanization . . ." (1955), pp. 432-433.

<sup>285</sup> The part played by agricultural improvements, sometimes called the Agricultural Revolution, has been emphasized by Weber, *The Growth of Cities in the Nineteenth Century* . . . (1899; 1963 ed.), p. 165. He notes that "The results of the enclosures starting in England at about 1760 were the extension of arable cultivation to inferior and waste lands, the destruction of the antiquated common-field system, whereby one third of the land lay fallow each year, the consolidation of small farms into large and the consequent introduction of the principle of rotation of crops, of roots and artificial grasses, and other improved methods. The common-field system, according to Arthur Young, yielded 17-18 bushels of wheat per acre, the new system of large farms 26; the fleece of sheep pastured on common fields weighed only 3½ pounds as compared with 9 pounds on enclosures." He also noted that the average weight of animals at the Smithfield Market had risen during the eighteenth century as follows: cows, 370 lb. in 1710 and 800 lb. in 1795; calves, 50 lb. and 148 lb.; sheep, 28 lb. and 80 lb.; and lambs, 18 lb. and 50 lb.

<sup>286</sup> Estimates cited in Hauser, "World and Asian urbanization . . ." (1957), p. 58. Other estimates for 1800 appear in Woytinsky and Woytinsky, *World Population and Production* . . . (1953), table 54; they do not differ greatly from the estimates provided by Davis and Hertz, except that the total for Asia (6.1 million) is noticeably lower. See also Hoyt, "The growth of cities from 1800 to 1960 . . ." (1963).

<sup>287</sup> United Nations, *Growth of the World's Urban* . . . (1969), table 8.

that lived in such agglomerations. Between 1950 and 1960 the agglomerated population as a percentage of world total population increased from 21 to 25, a larger increase than that observed in previous decades.

139. As discussed earlier, the pace of urbanization had slackened in Europe but accelerated in the less developed regions in the twentieth century. However, the stepped-up pace in world urbanization noted above for the 1950-1960 period, compared with immediately preceding decades, affected both the developed and the developing regions, though it was more significant in the latter. Thus, in the developing regions the percentage of population in agglomerations of 20,000 or more inhabitants, which had been only about 6 per cent in 1920 and 11 per cent in 1950, had risen to 15 per cent by 1960. The more developed regions, on the other hand, increased their urban percentages from 29 per cent in 1920 to 40 and 46 per cent in

1950 and 1960, respectively (table VI.6). Urbanization is seen to have advanced most conspicuously in the USSR and Latin America.<sup>288</sup>

140. Rapid growth was also observed in the large-city population during this period (table VI.7). During the 1950-1960 decade the average annual rate of increase in the population of cities of 100,000 or more inhabitants had advanced to 5.7 per cent in the developing regions, and 2.9 per cent in the more developed regions (table VI.8). The increasing concentration of urban population in large cities, particularly in the developing regions, is seen in the fact that growth rates of the large-city population exceeded those of the agglomerated population as a whole throughout the period.

<sup>288</sup> For a more detailed analysis of recent urbanization trends in Latin America, see Durand and Peláez, "Patterns of urbanization in Latin America" (1965).

141. As shown in table VI.9, during 1920-1960 the rural and small-town population of the more developed regions increased by only about 10 per cent, and since small towns probably grew more rapidly, it can be assumed that the more strictly rural populations actually decreased. But in the less developed regions, despite the rapid growth of the population in agglomerations of 20,000 or more inhabitants, which has already been noted, the rural and small-town population increased by one half in the forty years; undoubtedly the increase in strictly rural population (excluding small towns) was also very substantial.<sup>289</sup> Moreover, the figures show that as a result of the accelerated growth of total population, the annual growth rate of rural and small-town population in the developing regions was higher in 1950-1960 (1.5 per cent) than it had been throughout the period (1.1 per cent during 1920-1960).<sup>290</sup>

142. In summary, it may be noted that the modern cycle of urban growth began in Europe, roughly coincident with the onset of the Industrial Revolution, that it spread from there to other regions which are presently economically developed, and finally and even more massively, to the presently less developed regions. It does not follow, however, that the earlier conditions in Europe have been reproduced elsewhere. A review of conditions attending urbanization is presented in section D below.

#### (a) Urban localities

143. The increasing scale of large urban settlements has been a striking feature of urban population growth in all parts of the world in the twentieth century. It has been estimated that around 1800 there were 750 cities with 5,000 or more inhabitants, 200 with 20,000 or more inhabitants, and only forty-five with 100,000 or more.<sup>291</sup> By contrast, the world's forty-fifth largest city in 1970 might have had about 2,600,000 inhabitants.<sup>292</sup> There were probably at the most one or two cities of 1,000,000 or more inhabitants in 1800 and possibly none.<sup>293</sup>

<sup>289</sup> For more recent dates the United Nations has estimated urban and rural populations so far as possible in conformity with recent definitions of these two categories in each country. The results show that between 1960 and 1970 the rural population in Europe and other more developed regions decreased, while that in the developing regions increased by 1.8 per cent per annum on average. United Nations, *Monthly Bulletin of Statistics*, November 1971 (1971), table B.I.

<sup>290</sup> Rates computed from data in table VI.9.

<sup>291</sup> Estimates by Davis and Hertz, cited in Hauser, "World and Asian urbanization ..." (1957), p. 57.

<sup>292</sup> Davis, *World Urbanization 1950-1970*, vol. 1 ... (1969), p. 239.

<sup>293</sup> See lists of cities provided in Woytinsky and Woytinsky, *World Population and Production* ... (1953), pp. 120-122, and also Weber, *The Growth of Cities in the Nineteenth Century* ... (1899; 1963 ed.), p. 450. London had not yet achieved a million inhabitants. It is possible that one or two cities in China then approached, or even surpassed, a million population. If the accounts of Marco Polo can be trusted, Kinsai (on the site of present Hangchow in China) may have reached three million inhabitants in the thirteenth century. According to one estimate, the population of Edo (now Tokyo) may have exceeded one million by 1721 and may have generally remained above a million at many dates during the early part of the nineteenth century. Manchester, "Tokyo" (1964), p. 274. See also Tsuchiya, *An Economic History of Japan* (1937), p. 195; Hoyt and Pickard, "The world's million-population

Although it is believed that some cities of 1 million or more inhabitants could possibly have existed in various pre-industrial cultures, e.g. in China during the Sung Dynasty, if not also Rome and Constantinople, there is a strong probability that many of the population estimates of ancient cities were exaggerated.<sup>294</sup> Even by the end of the nineteenth century, the cities of 100,000 or more were still considered as of exceptional size. Weber, writing in 1899, defined the "great city" as one having 100,000 or more inhabitants.<sup>295</sup> By the end of the nineteenth century there were only about eleven cities of one million or more inhabitants,<sup>296</sup> London still being the largest.

144. Prior to the nineteenth century, the city of 100,000 or more inhabitants was relatively rare. At the beginning of the sixteenth century Europe had perhaps six or seven such cities. Three hundred years later, at the end of the eighteenth century there were still only twenty-two.<sup>297</sup> It was only during the nineteenth century that cities of 100,000 or more began to proliferate, particularly in Europe. By 1850, there were forty-two in Europe and by 1895 there were 120.<sup>298</sup> The proliferation of cities of 100,000 or more in Russia and the United States occurred mainly in the latter part of the nineteenth century. In 1863, there were only three cities in Russia with more than 100,000 inhabitants.<sup>299</sup> By 1897 the number of such cities had risen to seventeen.<sup>300</sup> In 1850, there were only six cities in the United States with more than 100,000 inhabitants. By 1900 the number of such cities had reached thirty-eight.<sup>301</sup> According to Davis's estimates, there were almost 1,600 cities with more than 100,000 inhabitants in the world in 1970.<sup>302</sup>

145. Over the past century and a half, remarkable shifts have occurred in the distribution of the world's big-city population among the major geographical areas. Table VI.10 shows that in 1800 Asia and Europe together may have contained almost 95 per cent of the population of the world's forty-five cities of 100,000 or more inhabitants. Asia's share at that time was twice as large as Europe's share. By 1900, the situation was reversed—Europe had about twice as much as Asia, and there had

metropolises" (1969), p. 198. Some authors believe that Edo was exceeded in size by Peking but little specific information is generally available to indicate the population of Peking during the past two centuries.

<sup>294</sup> See, for example, studies reviewed in Sjoberg, *The Preindustrial City* ... (1960), pp. 80-84, especially Russell, "Late ancient and medieval population" (1958), pp. 37-101.

SOURCES: Estimates for 1800, 1850 and 1900 compiled from cities listed in Woytinsky and Woytinsky, *World Population and Production ...* (1953), pp. 120-123. It is assumed, in addition, that either Peking or Tokyo could have exceeded 1 million population in 1800 and 1850 (see discussion in foot-note 293 earlier in this section). Figures for 1950 and 1970 are based on recent estimates of the United Nations.

been a significant growth in the share of this population in the Americas, of which the greater part was in the United States. Whereas the early urban growth in Asia had been mainly a function of total population size which was always greater than Europe's, Europe's big-city population had overtaken that of Asia through a process of population rearrangement and concentration in cities associated with industrial development. By the middle of the twentieth century, however, it appears that Asia had again overtaken Europe. The North American share of big-city population has remained important throughout the present century. According to projections by Hoyt, Asia may again claim the majority of the world's population in cities of 100,000 or more inhabitants by the end of the present century, as it did in earlier times.<sup>303</sup>

146. The number of cities with 1 million or more inhabitants has grown very large during the course of the present century. (The increasing number of million and multi-million cities is traced in table VI.11.) During the first half of the present century the number of cities of one million population or larger increased from eleven to seventy-five, and by 1970 there may have been about 162 such cities. Meanwhile, the number of cities at least double that size (with 2 million or more inhabitants) increased from three in 1900 to twenty-six by mid-century and perhaps fifty-eight by 1970. One agglomeration (New York), which already had more than 8 million

inhabitants by 1920, came to exceed 16 million by 1970. Meanwhile, eight more agglomerations have reached populations of 8 million or more inhabitants. It must be admitted that the size comparison of large agglomerations can only be tentative since in each case the outer boundary is quite debatable.<sup>304</sup>

147. Thus, the most unique feature of contemporary urbanization appears to be the proliferation of settlements of unprecedented size. This happened earliest in the more developed regions. As shown in table VI.12, in those regions the population of cities of 1 million or more inhabitants, already represented 44 per cent of the population in places of 100,000 or more inhabitants in 1920, whereas the corresponding percentage for the developing regions was 22. Between 1920 and 1960 this proportion increased much more rapidly in the developing regions than in the more developed, thus narrowing the gap between them.

148. According to the estimates of Woytinsky and Woytinsky, there were eleven cities with a population of at least 1 million in 1900, six of which were in Europe. Europe's share of the total population in cities of this size was close to 50 per cent.<sup>305</sup> Estimates for 1970 show

<sup>304</sup> The numbers for 1970 cited here are derived from United Nations estimates. For other estimates see Davis, *World Urbanization 1950-1970*, vol. 1 ... (1969).

that Europe's share of the world's population in cities of a million or more inhabitants had fallen to about one-fifth, while Asia's share was about twice as large (table VI.13).<sup>306</sup>

#### (b) Size of rural localities

149. Little attention has been given by demographers to the size of rural localities, although there is some quantity of scattered information on the subject in geographic literature and atlases. Whatever mention of rural settlement patterns occurs in demographic literature has been generally in terms of over-all rural density ratios, which tell little about the nature of the population settlement pattern. Areas with the same over-all average density may differ greatly in the character of their settlement patterns: they may contain large areas of uninhabitable territory; they may be characterized by settlement in large villages with 10,000 or more inhabitants; they may be covered with thousands of small, almost invisible villages; they may contain mostly dispersed settlement in isolated family homesteads; they may contain primarily large estates and plantations; or they may contain any mixture of all these settlement patterns.

150. Actual settlement forms in different countries, or parts of countries, are so diverse that to summarize and compare them is exceedingly difficult and has seldom been attempted.<sup>307</sup> These patterns are, however, of

<sup>306</sup> These figures, which are estimates of the United Nations, do not differ greatly from estimates derived from Davis, *World Urbanization 1950-1970*, vol. 1 ... (1969).

<sup>307</sup> See, however, the discussion later in this section of the recent effort of Johnson, *The Organization of Space ...* (1970), to compare settlement hierarchies.

considerable importance, since the developmental needs and potentialities of the rural habitat are dictated to a considerable extent by the sizes of settlements and distances between them, in relation to other conditions such as the over-all population density and the means of transport. It is also possible to devise deliberate policies designed to modify the settlement patterns in ways more favourable for economic and social development.

151. Generally speaking, rural settlement patterns can be broadly classified as dispersed or clustered.<sup>308</sup> Dispersed settlement is characteristic of areas in which farms are operated by single family-owners who live on the farm itself. Clustered rural settlement takes the form of more or less sizeable villages. Farmers reside in the villages and commute daily to farm lands located elsewhere.

152. There are advantages and disadvantages in each type of settlement pattern. The dispersed pattern has the advantage that farm residences are not spatially separated from the place of work. The farmer is able to pay careful attention to the maintenance of buildings, stores, fences, livestock and implements on a full-time basis. On the other hand, it has the disadvantage of isolation. Social and economic services are more easily provided to clustered village settlements, where there is also the opportunity for daily human interaction and the emergence of social functions and roles. However, the commuting distance to fields can become excessive in areas where modern transportation facilities are not available.

#### (i) Dispersed settlement

153. A dispersed settlement pattern where the population engaged in agriculture resides on isolated farms operated by single families is predominant in the rural areas of Canada and the United States.<sup>309</sup> In the United States in 1960 over 80 per cent of the rural population (defined as population outside places of 2,500 or more inhabitants) resided in open country. Moreover, the data listed by decades back to 1890 indicate that this pattern has not undergone any fundamental change.<sup>310</sup> With the sharp drop in the number of farms and farm population in recent years, the organization of commercial and public facilities for farm residents has become increasingly difficult.<sup>311</sup>

<sup>308</sup> Numerous examples of both clustered and dispersed agricultural settlement have been listed by Demangeon. The relative clustering or dispersion of agricultural population may be influenced by many factors including topography and the distribution of water resources, ethnic traditions, the systems of land tenure, fragmentation or consolidation of individual land holdings, needs for protection, and types of agricultural technology. See Demangeon, "L'habitat rural" (1952) and his "La géographie de l'habitat rural" (1952). Various configurations of village settlement since neolithic times are described and illustrated in Hilberseimer, *The Nature of Cities* (1955), pp. 16-21.

<sup>309</sup> The Canadian pattern is described in Camu, Weeks and Sametz, *Economic Geography of Canada* (1964), pp. 166-168. For statistics and discussion of the rural settlement pattern in the United States, see United States Bureau of the Census, *People of Rural America* (1968).

<sup>310</sup> United States Bureau of the Census, *People of Rural America* (1968), p. 22.

<sup>311</sup> Among the most serious problems is the organization of medical facilities in rural areas of steadily decreasing population density. In the most thinly populated counties of the United States there is now only one doctor for every 2,145 residents. See *Wall Street*

(Continued on next page)

154. Scattered settlement is also prevalent in Sweden, and the settlement density is very low in many parts. For these reasons many small localities of several hundred inhabitants may have to perform the same functions as larger urban places in more densely populated countries. Thus, small centres of 500-1,000 inhabitants are not regarded as rural in Sweden even though they would normally be considered as such in most countries.<sup>312</sup>

## (ii) Clustered village settlement

155. While examples of the dispersed pattern of rural settlement can be found in most areas of the world, the clustered village pattern is more prevalent both presently and historically. The settlement pattern in much of Eastern Europe consists of small villages.<sup>313</sup> In the Soviet Union the origin of small villages dates back to the feudal epoch, when they served as fortresses, garrisons, regional centres and other non-industrial communities.<sup>314</sup> There are about 700,000 rural communities, of which 70 per cent have fewer than 100 inhabitants each. There are about eight villages per collective farm, on the average.<sup>315</sup> This fragmentation is said to be in large part the reason for the small scale of agricultural production; it impedes the mechanization of agriculture and the improvement of culture and services for the rural population,<sup>316</sup> and concentration of rural population in larger settlements is planned.<sup>317</sup>

156. In much of southern Italy the rural population is said to be over-concentrated relative to available means of transportation to fields. Peasants live in hill-top villages of 5,000, 10,000 or even larger populations which are not within easy reach of the fields.<sup>318</sup> Although a highly clustered pattern of rural settlement may sometimes be disadvantageous from the point of view of agricultural efficiency, such a settlement pattern may be very convenient if it is desired to introduce industrial and service

employments into rural areas. In Hungary, for example, the existence of mammoth villages of 10,000 inhabitants or more made it possible for industrialization to be undertaken in the Great Hungarian Plain with rather low social investment.<sup>319</sup> The majority of Hungary's villages, however, have fewer than 5,000 inhabitants.<sup>320</sup> By far the larger part of Japan's six million farm households live in unincorporated hamlets or villages (*buraku*) ranging from a few score up to a thousand or more inhabitants.<sup>321</sup>

157. In Latin America a substantial proportion of the rural population resides in small population clusters. Many of these are so small that they are sometimes described as "dispersed settlements". The Economic Commission for Latin America defines the "dispersed" rural population as consisting of settlements of less than twenty people.<sup>322</sup> The next largest type of settlement is the *caserío* or hamlet. This is a loosely nucleated cluster of not more than 200 people. In every country of the region except Bolivia, Cuba, Haiti and Mexico, an important part of the rural population lives and works on large privately owned estates or *haciendas*. In physical patterns and in population size, the *haciendas* differ widely among themselves. There is usually a central nucleus with a mansion, administrative buildings, storerooms, often a chapel and a school, and the majority of resident families are likely to be grouped around it in a *villorrio* or *case-río*.<sup>323</sup>

158. Most Africans probably live in agglomerations of some kind rather than in dispersed, individual family huts and houses, though every gradation of "rural" settlement may be found from the large agrotowns of Yorubaland, the *ksour* (fortified villages) of Saharan Morocco, encampments of nomadic herdsmen, and groupings of huts in hamlets and villages, to the remarkably dispersed *shambas* of Rwanda and Burundi.<sup>324</sup>

159. In the Sudan, the nucleated village type of settlement is most common. Houses are clustered together according to a rather irregular pattern. The concentrated settlement pattern is to be explained in part by the generally sparse distribution of water supplies, but more especially by the need for security in the thinly populated countryside where until recently nomads had ranged uncontrolled.<sup>325</sup> Rural isolation of a special kind is

(Footnote 311 continued)

*Journal*, 27 October 1971, p. 1. For further discussion of size of place structure in rural United States, see Fuguitt and Field, "Some population characteristics of villages ..." (1972), and also Fuguitt, "The places left behind ..." (1971).

characteristic of some areas in Africa, such as Sierra Leone, where farmers live in small tribal villages which are tightly insulated from one another by forests and walls, even though they may be spatially not very far apart.<sup>326</sup>

### (iii) Scattered land parcels

160. It has often been common in village agriculture for a single farmer to divide his efforts between several scattered parcels of land.<sup>327</sup> The fragmentation of individual holdings has often resulted from inheritance institutions and sometimes from a custom that each farmer should be allocated portions of both good and poor land. The disadvantage is that much time is lost in carrying tools from one plot to another.<sup>328</sup>

161. Scattered land parcels have long been traditional in Japan,<sup>329</sup> and only during recent decades has the consolidation of land parcels started to occur in selected areas. Before the collective organization of farms was begun in China, most farms consisted of scattered strips and patches, often half a mile apart, among which the farmer had to divide his attention and to transport his plough.<sup>330</sup> In India the holding of a peasant may be in several pieces and the distance between one piece and another may be more than 1.5 kilometres. Attempts have been made in some parts of the country to bring about the consolidation of holdings. These efforts have not been conspicuously successful because of Hindu inheritance law which requires the distribution of land among all sons.<sup>331</sup>

### (iv) Transportation

162. In planning for separation of farm residences from farmlands, it is obviously important to consider what means of transportation are available for commuting from residences to the fields. In France, where the persistence of small villages and excessive fragmentation of holdings in many areas impede modernization, there is now hope that some consolidation can be accomplished, thanks to the development of modern transportation. Some planners have envisaged that the entire rural population (both farm and non-farm) might live in centres of 2,000-5,000 inhabitants from which the cultivators would

travel to their farms, all located within a radius of 15 kilometres.<sup>332</sup> By way of contrast, in Latin America the means of transportation available to the peasant is still mostly the horse and cart, although the use of the bicycle has become rather popular in the past few years. On the assumption that the commuting trip should consume no more than thirty minutes each way, it has been estimated that where ox-cart transportation is used, the maximum permissible distance between the farmer and his field can only be about three kilometres; with bicycles the distance could be about 7.5 kilometres; and with motor vehicles the distance could be as great as twenty kilometres.<sup>333</sup>

### (v) Collective organization of rural settlements

163. Various kinds of collective organization of agricultural work and habitation have been attempted in a number of countries, among them China, Israel, the USSR,<sup>334</sup> and various countries of Eastern Europe. In Hungary, for example, as a result of the growth in co-operative farming, isolated farmsteads are rapidly disappearing and their former inhabitants migrate to villages and towns.<sup>335</sup> In the Soviet Union, the farm population in the larger collective settlements is becoming increasingly to be housed in multi-storey apartment buildings,<sup>336</sup> although the single-family house is still predominant, as it is in the co-operative farms of most Eastern European countries, such as Bulgaria, Czechoslovakia, Hungary and Romania.<sup>337</sup>

164. By 1957 almost the entire agricultural population of China were members of co-operative farms. The average co-operative had about 160 households, or some 600 persons; the co-operatives were subsequently merged into larger units known as communes.<sup>338</sup> The largest *kibbutzim* in Israel have attained a population of 1,500-1,700; all meals are served in a communal dining hall, and child care and many other services are communally organized.<sup>339</sup>

### (vi) Role of small towns

165. Johnson has examined settlement hierarchies with special emphasis on the role of small towns in facilitating rural and national development. From the historic role of towns in Belgium and the Netherlands, he concluded that "a profound transforming influence can be exerted on rural hinterlands by cities that are not very large".<sup>340</sup> Where extensive rural areas are remote from cities, the prevalence or scarcity of intermediate and smaller towns

<sup>326</sup> Siddle, "The evolution of rural settlement forms in Sierra Leone ..." (1969), p. 33.

<sup>327</sup> Demangeon, "L'habitat rural" (1952), p. 156. At least one example has been described of a village in southern Italy in which 1,500 families farmed 9,000 scattered parcels of land. Carlyle, *The Awakening of Southern Italy* (1962), p. 36.

<sup>328</sup> In France it has been estimated that out of ten hours of paid work, there are only eight hours of actual work in a fragmented farm, as against nine and one-half hours of work in a consolidated farm. <sup>340</sup> Johnson, *The Organization of Space ...* (1970), p. 47.

may have great significance for development. As calculated by Johnson, the number of villages per town ranges from 23 to 41 in Italy, Greece, Lebanon, Sweden and Uruguay, but is high in Asian countries: 87 in Malaysia, 98 in Iraq, 99 in Syria, 117 in Turkey, 146 in Yemen, 185 in India, 269 in Iran and 355 in Indonesia.<sup>341</sup>

166. In China, the average ratio of villages to market towns was found to be around 18 to 1, according to the researches of Skinner.<sup>342</sup> In India, conditions in this respect are much less favourable. In 1961, there were more than 560,000 villages, averaging only 637 persons each, and less than 2,000 market towns.<sup>343</sup> For India to have the same village to market-town ratio as China would require more than 30,000 such towns. However, conditions vary in different parts of India and, according to Johnson, the ratio of villages to market towns ranged from a low of about 50 to 1 to a high of over 300 to 1.<sup>344</sup>

167. The role of the average small town in the more modernized nations is changing rapidly. The term "small town" has traditionally been equated with remote rural service centres. An analysis of United States census data for towns of less than 10,000 inhabitants during the decades 1940-1950 and 1950-1960 showed that existing towns are growing and a significant number of new small towns are being formed (although the group of towns with less than 1,000 inhabitants is decreasing). However, small towns in and near urbanized areas are growing more rapidly than towns in isolated rural areas.<sup>345</sup> The role of small towns in and around large agglomerations is distinctly different from the crossroad hamlets of isolated rural areas.

### 3. DEMOGRAPHIC COMPONENTS OF URBAN AND RURAL GROWTH

168. The differential levels of fertility and mortality in urban and rural areas have been discussed respectively, in chapter IV, section F and chapter V, section E. The discussion in this section is confined to a consideration of: (1) the combined effect of these components of change, that is, of natural increase; (2) the effect of migration, whether rural-to-urban, urban-to-rural, from smaller places to larger places etc.; and (3) the growth in urban areas due to reclassification of previously rural territory as urban.

169. Migration, as used here, refers to net migration. Although migration is usually a positive factor in the growth of cities, it must be remembered that large-scale migrations are occurring in all directions. In Poland during the period 1961-1965, the number of in-migrants to towns and cities was 2,467,000, but this was largely offset by out-migration of 1,890,000. Thus, out of a

gross exchange of 4,357,000 persons, the net gain to Polish urban areas was only 577,000.<sup>346</sup> In Greater Bangkok, place of birth statistics indicated that by 1960, 486,500 persons had migrated to Bangkok, while 144,500 had left Bangkok. The gross exchange between Greater Bangkok and the rest of Thailand, judged by life-time migration, involved some 631,000 persons, but the net gain was only 342,000.<sup>347</sup>

170. It is known that cities in Europe prior to the Industrial Revolution grew primarily by migration rather than natural increase.<sup>348</sup> In many cities there was actually a natural decrease rather than a natural increase. Early statistical evidence is afforded by the so-called "bills of mortality" begun in certain cities in the sixteenth and seventeenth centuries which almost uniformly showed more deaths than births each year. The cities then were actually consumers of population produced in the countryside. Indeed, it has been said that the rural-to-urban migrants "did little more than fill the vacant places caused by death."<sup>349</sup> That cities grew at all can only be attributed to migration. Captain John Graunt, an early demographer, estimated that in the early 1600s deaths caused by urban plague, no matter how numerous, could be replaced by in-migrants by the second year after the plague.<sup>350</sup> Thus, the process of urbanization came to be considered as a subtopic belonging under the more general subject of migration.

171. An important reversal occurred during the last century when many cities in Europe reached a point of self-maintenance and subsequently achieved an excess of births over deaths. Such a status was reached in Paris before the close of the eighteenth century, in London in 1800, in German cities in the first half of the nineteenth century, in Swedish cities in the mid-nineteenth century. Moreover, many cities were also growing by annexation of territory. According to Weber, during the course of the last century, a substantial proportion of the growth of some cities was due to incorporation of suburbs: for example, in Cologne 37 per cent, in Leipzig 44 per cent, in Paris 21 per cent, in Munich 17 per cent.<sup>351</sup>

<sup>346</sup> Kosiński, "The internal migration of population in Poland ..." (1970), p. 77.

<sup>347</sup> Goldstein, "Urban growth in Thailand ..." (1971), p. 2,897.

<sup>348</sup> Statistics referenced in this paragraph and the next were taken from Weber, *The Growth of Cities in the Nineteenth Century* ... (1899; 1963 ed.), pp. 230-257, which contains a review of statistical literature and comment on this subject.

<sup>349</sup> *Ibid.*, p. 233.

<sup>350</sup> As described in Weber, *The Growth of Cities in the Nineteenth Century* ... (1899; 1963 ed.), p. 233.

<sup>351</sup> In the present century in many western countries administrative expansion of cities, especially big cities, has failed to keep pace with the growth of the corresponding agglomerations with suburbs extending ever further beyond the rather rigid administrative boundaries. In recent decades, some big cities have actually incurred net population losses as a result of residential movements to their suburban zones, not reflected within the municipal limits. Thus, between 1960 and 1970 the forty-two cities in the United States with more than 300,000 inhabitants in 1960 had a population gain of only 2.0 per cent, the eighty-eight cities with 100,000 to 300,000 inhabitants had a gain of 12.6 per cent, while elsewhere in the country, i.e., in the combination of smaller cities, suburbs and rural areas, the population gain was 16.7 per cent. Virtually all of the 12.6 per cent gain in the middle-sized cities was due to

<sup>341</sup> *Ibid.*, p. 176.

<sup>342</sup> Skinner, "Marketing and social structure in rural China", part 1 (1964), p. 18.

<sup>343</sup> Johnson, *The Organization of Space* ... (1970), pp. 72, 83.

<sup>344</sup> *Ibid.*, p. 83. For a discussion of village settlement in India, see Nath, "The village and the community" (1961).

<sup>345</sup> Fuguitt and Thomas, "Small town growth in the United States ..." (1966). See also Lappo, "Geograficheskoe izuchenie naselennykh punktov ..." (1964).

172. The importance of an excess of births over deaths as a source of urban growth has continued to increase. While natural increase was previously much higher in the rural areas than in the urban areas, it is now quite possible that the levels may be more nearly the same in both urban and rural areas. On the one hand, it is believed that mortality may be generally lower in the urban areas than in the rural areas because of the greater prevalence of medical facilities in urban areas. On the other hand, fertility is also often lower in urban areas, so that the net excess of births over deaths can be similar in both urban and rural areas. This appears to be the case, for example, in the United Arab Republic, as shown in the following adjusted crude birth and death rates which have been estimated for urban and rural areas:<sup>352</sup>

	1934			1959		
	Urban	Rural	Difference	Urban	Rural	Difference
<i>Rates per 1,000 population</i>						
Birth rate .....	44.4	49.1	4.7	44.1	45.2	1.1
Death rate .....	29.5	36.0	6.5	17.8	19.4	1.6
Rate of natural increase .	14.9	13.1	1.8	26.3	25.8	0.5

In this instance the urban birth and death rates were each lower than the rural birth and death rates, but these differences were mutually offsetting so that the natural increases in both urban and rural areas were not very different. Despite the large fall in death rates from 1934 to 1959, this relationship remained approximately true.<sup>353</sup>

173. Where natural increase is similar in both urban and rural areas, the increases in the level of urbanization (that is, in the percentage of urban population) can be largely attributed to migration. In rapidly urbanizing areas, it has been observed that the cities often grow approximately twice as fast as the total population.<sup>354</sup>

the annexation of surrounding territory. Metropolitan Life Insurance Company, "Population growth in moderately large cities" (1972), p. 8.

<sup>352</sup> El-Badry, "Trends in the components of population growth in the Arab countries of the Middle East ..." (1965), pp. 144-145.

<sup>353</sup> Unpublished United Nations estimates of crude vital rates of urban and rural populations, around 1960, for the world and its major regions suggest that, on an average, differences in urban and rural rates of natural increase tend to be slight, though crude birth rates and crude death rates may differ more substantially.

	More developed regions			Developing regions		
	Urban	Rural	Difference	Urban	Rural	Difference
<i>Rates per 1,000 population</i>						
Birth rate .....	19.8	23.1	3.3	38.0	44.1	6.1
Death rate .....	9.0	9.5	0.5	15.3	21.6	6.3
Rate of natural increase .....	10.8	13.6	2.8	22.7	22.5	-0.2

It must be remembered that these are crude rates which are affected not only by fertility and mortality levels, but also by differences in age composition. As a rule, young adults are relatively more numerous in urban than in rural areas, and young adults tend to have higher age-specific birth rates and lower age-specific death rates than the remainder of the population.

<sup>354</sup> United Nations, *World Housing Conditions and Estimated Housing Requirements* (1965). Urban growth in Asia is said to be two to three times higher than the average growth of total popula-

If the natural increase component is the same in both urban and rural areas and the cities nevertheless grow twice as fast as the countryside, it can be supposed that, on the average, about half the increase in city population may be due to in-migration and the other half of the urban increase would be due to natural increase (given constant urban boundaries).

174. Statistical evidence concerning the relative contributions of the natural increase and migration components to urban growth is scattered and often non-comparable. Statistics from the Union of Soviet Socialist Republics indicate that in that country the contributions to urban increase provided by rural-to-urban migration and natural increase were roughly the same during the period 1959 to 1970—44 per cent and 41 per cent, respectively. The

factor of reclassification of localities was also quantitatively important: almost 15 per cent of the urban increase was attributable to the redefinition of previously rural settlements as urban.<sup>355</sup> The natural increase component of urban growth has been considerably augmented over time. Thus in the period 1926-1938, natural increase accounted for only about 18 per cent of urban increase; in the period 1939-1958, 20 per cent;<sup>356</sup> and in the period 1959-1970, 41 per cent.<sup>357</sup> In Poland, also, the contributions of the two components were nearly equal: in-migration represented 45 per cent of the urban growth, and the remainder was provided by natural increase during the period 1961-1965. (The effects of administrative changes were mostly offset by external migration abroad.)<sup>358</sup> Likewise, in Canada, the relative importance of migration and natural increase in the growth of all metropolitan areas combined appears to have been about equal during the period 1951-1961, though there was some variation among individual areas.<sup>359</sup> A study of Latin American countries during periods prior to 1950 showed that at that time the proportion of urban growth attributable to natural increase in nine countries ranged between 30 per cent and 58 per cent.<sup>360</sup> The contribution of natural

tion. United Nations, Economic Commission for Asia and the Far East, "Population growth and problems of employment ..." (1961), p. 14.

<sup>358</sup> Kosiński, "The internal migration of population in Poland ..." (1970), p. 77.

<sup>359</sup> Stone, *Urban Development in Canada* ... (1967), p. 179.

<sup>360</sup> United Nations, "Demographic aspects of urbanization ..." (1961), p. 110. In Brazil 29 per cent of the 1940-1950 increase in the eight largest agglomerations was said to be due to natural increase, while for smaller cities (those with 5,000 or more inhabitants) the natural increase component was 51 per cent. Beaujeu-Garnier, "Large overpopulated cities ..." (1970), p. 269.

increase appears to have been augmented during the decade of the 1950s, however. In a study of twenty Latin American countries, it was estimated that the natural increase component for these countries as a group was about 60 per cent between 1950 and 1960.<sup>361</sup> On the other hand, it appears that in African countries about 60 per cent of the urban increase during the same decade was due to migration.<sup>362</sup>

175. In several south Asian countries, the role of natural increase is said to be greater than that of migration. In Pakistan between 1951 and 1961, natural increase accounted for about 42 per cent of the urban increase, while migration accounted for no more than about 30 per cent. (The rest is attributed to definitional changes.<sup>363</sup>) In India, the contribution of natural increase to urban growth in the period 1951-1961 was almost 70 per cent.<sup>364</sup> It has been estimated that during the three previous decades the contribution of natural increase to urban growth ranged between 30 and 60 per cent.<sup>365</sup> An analysis of the available data relating to place of birth of the urban population in several Middle Eastern countries showed that natural increase rather than migration has been the predominant factor in urban growth. Internal migration (which in this instance includes town-to-city migration as well as rural-to-urban migration) has accounted for only about a fifth of the total urban growth in the Syrian cities of Damascus and Aleppo, about a third of the urban growth in Iraq and up to half of the urbanization of Jordan.<sup>366</sup>

176. In Chile, the natural increase component of urban growth is considerably greater than the migration component. Thus, it is estimated that natural increase accounted for 70 per cent of city growth during the period 1952-1960.<sup>367</sup> The large relative contribution of natural increase to urban growth in Chile is attributed to high rates of natural increase in the cities.<sup>368</sup> In the United States, also, natural increase has been the main contributor to urban growth; it accounted for more than three quarters of metropolitan population growth during the period 1960-1965.<sup>369</sup> This represented a substantial rise in the role of natural increase as compared with the previous period (1950-1960) when natural increase

contributed 65 per cent of the urban growth.<sup>370</sup> The role of rural-to-urban migration is decreasing relative to urban natural increase in the United States because the level of urbanization is already high and the farm population is approaching minimum levels.<sup>371</sup> Rural depopulation is occurring in other developed countries also.<sup>372</sup>

177. While the relative contribution of rural-to-urban migration to urban growth in some highly urbanized areas such as the United States may now be less significant than it once was, the negative impact on the relatively small remaining rural population is increasingly important. In a comparative analysis of metropolitan and non-metropolitan economic areas of the United States, it was found that more than half of the natural increase occurring in the non-metropolitan economic areas was offset by net out-migration.<sup>373</sup> In the less developed countries as a group, it has been estimated that rural-to-urban migration during the 1950-1960 decade might have been about one-fourth as large as natural increase in the non-city population.<sup>374</sup> In these countries, however, the ratio of rural out-migration to natural increase varies greatly from one country to another and from one time period to another. Data from Tunisia, for example, indicate that the ratio of rural out-migration to rural natural increase might have risen from about 20 per cent during the decade 1936-1946 to about 40 per cent during the decade 1946-1956.<sup>375</sup> While variations between countries in Latin America are wide, it has been roughly estimated that, for the region as a whole, approximately half of the natural rural population increase of 3 per cent per year has been moving out of the rural category.<sup>376</sup> In a study of Yugoslavia during the period 1948-1961, it was shown that smaller settlements had greater losses relative to natural increase than larger settlements. Thus, settlements with 300 to 500 inhabitants recorded a population

<sup>370</sup> *Ibid.* Earlier data for the forty-five largest metropolitan areas of the United States in 1960 indicate that for persons 10 years of age and over the contribution of natural increase was 67 per cent during the decade 1930-1940; 34 per cent during the decade 1940-1950; and 57 per cent during the decade 1950-1960. The high percentage contribution of urban natural increase during the 1930s was the result of a relative decline in net rural-to-urban migration during the depression of that decade when urban employment became scarce. Data adapted from Miller, *Net Intercensal Migration to Large Urban Areas of the United States* . . . (1964), p. 4.

<sup>371</sup> Farm population as a proportion of total population in the United States declined from about 35 per cent in 1910 to 17 per cent in 1950, to 8.7 per cent in 1960, to 6.4 per cent in 1965, and to 5.1 per cent in 1969. Data for 1910 and 1950 from International Labour Office, *Why Labour Leaves the Land* . . . (1960), p. 21; data for 1960, 1965 and 1969 from United States, Department of Agriculture, *Agricultural Statistics, 1970* (1970), p. 440.

<sup>372</sup> In France, for example, the population of agricultural households declined from 18 per cent of the total population in 1962 to 14.5 per cent in 1968, and by 1975 the percentage is projected to decline still further to 11.5 per cent. <sup>369</sup> United States, Advisory Commission on Intergovernmental Relations, *Urban and Rural America* . . . (1968), p. 16.

increase of about one quarter of their natural increase; settlements of 500-1,000 inhabitants—about one half; and settlements of 1,000 to 2,000 inhabitants—about three quarters. In settlements with 2,000-5,000 inhabitants the population gain was roughly equal to natural increase, while the other groups of settlements (with over 5,000 inhabitants) recorded a growth which was considerably larger than the natural increase of population.<sup>377</sup>

178. Whereas the range of variation in the components of growth for the combined urban areas and rural areas is considerable, the variation among individual cities is even greater. While 60 per cent of the growth of Paris between 1954 and 1962 was due to migration,<sup>378</sup> in London between 1951 and 1961 over 70 per cent of the growth was attributable to natural increase. Studies based on place of birth statistics also show great diversity. In a survey carried out in Djakarta in 1954, it was found that 74 per cent of the Indonesian household heads interviewed had been born outside the city.<sup>379</sup> On the other hand, in Greater Bangkok in 1960, only one quarter of the native-born Thais had been born in other provinces.<sup>380</sup> Place of birth statistics for African cities also show wide inter-city variation. In Abidjan in 1965, only 29 per cent of the total population and only 7 per cent of the 112,000 persons over 20 years of age had been born in the city. In fifteen West and Middle African cities, the percentage of the population which had been born there varied from a high of 62 per cent for Bathurst to a low of 26 per cent for Douala and Libreville and it averaged about 42 per cent in the early 1960s.<sup>381</sup> In individual cities, as opposed to total urban population, some of the in-migration would have come from other cities rather than the countryside.<sup>382</sup>

179. Migration from other cities can represent important sources of growth for individual cities. Results of a 1962 survey of Greater Santiago showed that two thirds of the in-migrants had arrived from other urban places (places of 5,000 or more inhabitants in 1952). Despite the fact that in 1952 almost 50 per cent of Chile's population outside Santiago was genuinely rural, only 13 per cent of the in-migrants had come from such origins. The balance had come from areas classed as semi-urban. Moreover, the migrants had moved very little before their journey to Santiago. Among those who were 15 years of age or older at the time of migration, more than half had moved directly from their place of birth to Santiago.<sup>383</sup> In Middle Eastern countries, the flow of migration has been typically from rural areas to metropolitan centres or from towns to metropolitan centres rather than from

rural areas to intermediate-sized towns, which are few in the region.<sup>384</sup> Investigations made in Latin America do not support the hypothesis that "step-wise" migration has been important there; that is, that migrants have moved first to the smaller local urban centres, then to the great cities. In at least one Latin American country, Colombia, the admittedly fragmentary evidence suggests a "fill-in" migration pattern—that is, a pattern in which rural migrants move to villages and small towns, while "other" residents move from villages and small towns to larger towns and cities.<sup>385</sup>

180. The contribution of natural increase cannot be clearly separated from the contribution of migration, for it must be remembered that part of the urban natural increase occurs among rural-to-urban migrants. This is especially important in countries where the level of rural-to-urban migration is high. The amount of natural increase among rural-to-urban migrants was found to be an important component of urban growth in the Soviet Union, for example.<sup>386</sup> It has, likewise, been observed that the newly urban population in Latin America, which consists predominantly of young adults retaining typically high rural fertility rates, accounts for an important proportion of urban natural increase.<sup>387</sup> In a recent study of the Lima Metropolitan Area, it was revealed that approximately 64 per cent of the currently mated women between the ages of 15 and 49 were in-migrants.<sup>388</sup> It has also been estimated, in a study of the urban area of the State of Guanabara, Brazil, that between 45 and 50 per cent of all pregnancies in this population occurred among in-migrants, about two thirds of them among in-migrants from rural areas.<sup>389</sup> In some countries it may be true that limitations on housing facilities and poor living conditions in urban areas motivate incoming migrants to restrict the size of their families permanently, or temporarily. In other areas of the world the family size of rural-to-urban migrants who live in squatter settlements at the peripheries of larger cities has been notably high. Several studies which compared the fertility of rural-to-urban migrants with that of urban natives were reviewed in section B above.

181. The question of fertility differences between migrants and non-migrants is clouded by many complexities and the issue is not likely to be resolved without further carefully controlled study in a diversity of national

<sup>388</sup> Survey sponsored by the Latin American Demographic Centre (CELADE) at Santiago and the Dirección Nacional de Estadística y Censos in Peru, as described in Weller, Macisco and Martine, "The relative importance of the components of urban growth in Latin America" (1971), p. 230.

<sup>389</sup> Martine, *Internal Migration and Its Consequences: The Case for Guanabara State*, unpublished Ph.D. dissertation cited by Weller, Macisco and Martine, "The relative importance of the components of urban growth in Latin America" (1971), p. 230.

and socio-economic contexts.<sup>390</sup> For example, it would not be unreasonable, on purely logical grounds alone, to suppose that where accommodation to urban circumstances is difficult, the age-specific birth rate pattern of migrants may be different from that of urban natives. Problems faced by migrants, such as finding stable employment and establishing a permanent family residence, could be influential factors in decisions to postpone marriage and births until later ages. In a study of San Juan, Puerto Rico, a "crossover" effect was observed. The number of children ever born per 1,000 married women was lower for in-migrants than for urban natives at ages of less than 35, but higher than urban natives after the age of 35.<sup>391</sup> Such a "crossover" in total fertility at an age when one can presume that most child-bearing is complete has also been observed in an analysis of United States census data for 1960.<sup>392</sup> In another study, in Bombay, India, the factor of duration of urban residence was considered, with age controlled. It was found that within each age group the number of children ever born per 100 married mothers was greater in families where the husband had resided within the city for a long period of time than in families where the husband had arrived only recently.<sup>393</sup>

## D. Factors affecting urban-rural population distribution

### 1. OBSERVED CONDITIONS ATTENDING MODERN URBANIZATION

#### (a) Pre-industrial antecedents

182. It has been shown in section C above that the growth of urbanization throughout the world has been uniquely a characteristic of recent history. While a few cities have existed for millennia, it is only within the past two hundred years that they have become so universally apparent. Large urban populations could exist only when and where agricultural productivity had substantially increased beyond the subsistence level, since urban dwellers have not generally produced their own food and have depended upon non-urban populations to generate a surplus.<sup>394</sup> Early societies, with their low levels of technical development and capitalization of agricultural production and their generally small-scale techniques, therefore, were limited in their abilities to support any large urban populations. In addition, technological

limitations prevented the transportation of surpluses to distant areas.<sup>395</sup>

183. Under such conditions, the population was usually distributed more or less in accordance with the productivity of the land.<sup>396</sup> Population was probably most heavily concentrated on lands which could produce large returns with minimum equipment, while other lands were less densely settled. Although a relatively uneven distribution of population resulted, there were few settlements that could be considered as urban.

184. The early cities that existed performed functions that were mainly political. They produced little industrial output and the levels of productivity were low by current standards. Administrative and garrison towns were often created by the Greek, Roman, Chinese and Latin American Empires for the purposes of controlling conquered territories and facilitating the exploitation of their resources, especially foodstuffs.<sup>397</sup> In these early periods an agricultural surplus was often generated by taxing or appropriating a part of the food produced in return for protection. The producer was forced to extract a surplus from the land when otherwise he would have preferred more leisure once the needs of his immediate family were met. As the institutions became formalized, those who provided the protection, those who administered the taxes, and those who supplied the services and equipment necessary for such functions began to reside in more permanent structures within walled towns or "political" cities.<sup>398</sup>

185. The populations of these pre-industrial cities soon became highly dependent upon the economic activities that occurred within, especially trade. Technological improvements, especially in transportation and communications,

<sup>395</sup> Weber, *The Growth of Cities in the Nineteenth Century* . . . (1899; 1963 ed.), p. 163, observes that the existence of cities presupposes a surplus food supply, which in turn requires either very high fertility of the soil or a fairly well advanced agricultural technology and, in either event, convenient means of transportation. "All three conditions were present in the river valleys of the Nile and Euphrates when the first great cities of history arose—Thebes, Memphis, Babylon, and Nineveh. No accurate estimates of the number of their inhabitants exist; but as the Greeks, who had cities of their own with at least 100,000 inhabitants, regarded the ancient cities with wonder, it may safely be said that they were great cities. Similar conditions were present during the period of Roman city civilization, The high perfection to which the arts of agriculture had been brought . . . permitted the existence of a large number of Oriental cities with a population of 100,000 or more in the first century before Christ. Two cities, Rome and Alexandria, probably attained a population of half a million souls each—a number reached by no other cities until the end of the seventeenth century (London and Paris)." On the other hand, Jacobs believes that the generally accepted assumption that the growth of cities required an agricultural surplus is false. She argues that cities could easily have appeared within an early industrial society before the development of agriculture, and that there is little empirical proof that agriculture had to develop first. See her *The Economy of Cities* (1969). While possible in isolated instances, it seems unlikely that large-scale urbanization could have been supported under such conditions.

<sup>396</sup> George, *Introduction à l'étude* . . . (1951), pp. 122-123.

<sup>397</sup> See Sjöberg, *The Preindustrial City* . . . (1960); also his "The rise and fall of cities . . ." (1969).

<sup>398</sup> Boulding, "The death of the city . . ." (1963), pp. 134-135. It is interesting to note that the earliest hieroglyphics referring to a city were composed of a circle with a cross within it, signifying a crossroad surrounded by a wall. Lopez, "The crossroads within the wall" (1963).

<sup>390</sup> A chronologic listing of past studies of the relationship between migration and fertility is provided in Macisco, Bouvier and Renzi, "Migration status, education and fertility . . ." (1969), pp. 183-186.

<sup>391</sup> *Ibid.*, p. 171.

<sup>392</sup> Macisco, Bouvier and Renzi, "Migration status, education and fertility . . ." (1969), pp. 183-186. The possibility of a cohort factor cannot be dismissed however.

<sup>393</sup> El-Badry, "A study of differential fertility in Bombay" (1967), p. 639.

<sup>394</sup> See, for example, Weber, *The Growth of Cities in the Nineteenth Century* . . . (1899; 1963 ed.), pp. 160-169; Gras, *An Introduction to Economic History* (1922); Sjöberg, *The Preindustrial City* . . . (1960); Mumford, *The City in History* . . . (1961), pp. 3-28; Lampard, "Historical aspects of urbanization" (1965); Hauser, "Urbanization—problems of high density living" (1968), pp. 187-189.

not only stimulated increased agricultural productivity, but also made it possible to administer increasingly large and diverse regions.<sup>399</sup>

186. The emergence of these factors during the economic transformations of the Middle Ages changed the basic nature of the urbanization process. As the city itself became more productive, the need for forceful exploitation of farmers declined. The city was thus transformed from a political to an economic centre.<sup>400</sup> The importance of transportation and communication technology became further accentuated. This is most evident in the case of the modern metropolis, which is essentially economic in purpose, and which depends upon trade for its very survival.<sup>401</sup>

187. The process of modern urbanization began with the Industrial Revolution, first in England, from which it spread to the European continent, and, especially after 1850 with the development of the steamship and railway, to the overseas areas of European settlement. This process reflected the changes in economic opportunities which were generated by structural changes in production and consumption. Massive rural-urban migration was the means by which people responded to changing economic opportunities, leading to a drastic redistribution of population.<sup>402</sup> Continually improved methods of production as a consequence of the agrarian and industrial revolutions were associated with the breakdown of relatively self-sufficient local and regional markets and their integration into national, and eventually international, markets. The increased agricultural output permitted an ever larger proportion of the population to engage in non-food producing activities and, especially at the beginning, provided a growing market for the expanding production of the new manufacturing sector.<sup>403</sup> The expansion of manufacturing industries and the services of the related tertiary industries was proportionately much greater than

that of the agricultural sector—among other reasons, because of the relative inelasticity of demand for food products. These changes in the structure of production were accompanied by changes in the demand for labour, one of the principal factors of production. A relatively diminishing need for agricultural labour was matched by correspondingly increased needs in the more rapidly expanding, urban-based sector. Rural-urban migration in this sense represented the adjustment of labour supply, which at the outset was predominantly rural, to the rural-urban shift in labour demand. It is within this economic context that the various push and pull factors under review have exercised their effect.

### (b) *The beginnings of modern urbanization*

#### (i) *Economic determining factors*

188. The main determining factors of the massive rural-urban migration which had its beginnings in northern and western Europe in the nineteenth century were economic. Improvements in agricultural techniques which began in the early eighteenth century resulted in a marked rise in the level of living and in declining mortality,<sup>404</sup> and perhaps also in somewhat higher fertility. Rural population pressure, the combined effect of more rapid population growth<sup>405</sup> and a proportionately smaller demand for agricultural labour resulting from improved agricultural efficiency, at first found an escape outlet in emigration overseas. Late in the eighteenth century in England, incipient industrialization began to offer an alternative outlet in the form of movement from country to town.<sup>406</sup> This alternative was available only on a limited scale to other countries of Western Europe until the second half of the nineteenth century when the urban economy became able to absorb more of the surplus rural population.<sup>407</sup> During this latter period there was a reduced demand for agricultural labour and population pressure became even more intense when the development of the railroad and steamship opened up the rich, virgin prairie lands of North America, Russia, Argentina and Oceania, and made it possible for Europe to import certain agricultural products at lower cost than they could be produced domestically.<sup>408</sup> In this sense, rural-to-urban migration represented one form of adjustment to increasing rural population pressure. This adjustment varied in detail from one country to another. In every instance, however, the main factor of rural-to-urban migration was the shift of employment and income opportunities from agriculture to other activities.

<sup>399</sup> One of the remarkable features of Roman civilization was its advanced state of construction engineering. This was reflected in the extensive irrigation and highway networks that remain in evidence today, which increased the productive and administrative capabilities.

<sup>400</sup> Boulding, "The death of the city . . ." (1963). On the functions of mediaeval cities, see Hoselitz, "The role of cities in the economic growth . . ." (1969), particularly pp. 235-239.

<sup>401</sup> Highly industrialized and urbanized nations such as the United Kingdom produce only part of the food that they consume, obtaining the remainder through trade with countries all over the world.

<sup>402</sup> Kuznets, "Introduction: population redistribution, migration . . ." (1964), p. xxiii. This explanation has been characterized as "the generally accepted theory of the relationship between economic growth and occupational structure". See International Labour Office, *Why Labour Leaves the Land . . .* (1960), p. 189. Weber's explanation in terms of the "economic organization of society" is essentially the same theory. See his *The Growth of Cities in the Nineteenth Century . . .* (1899; 1963 ed.), pp. 157, 209-222. For examples of other migration studies in which use is made of this theory, see Daragan, "Economic development and internal migration" (1967), pp. 487-488; Konstantinov, "Rural-urban migration as a factor . . ." (1967), pp. 499-502; Medina Echavarría and Hauser, "Rapporteurs' report" (1961), pp. 36-37. Davis defined several phases of internal migration which he considered to be not merely responses to economic change, but also necessary for such change. See his "Internal migration and urbanization . . ." (1955).

<sup>403</sup> Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 98-101.

<sup>404</sup> See chapter V, section G; Weber, *The Growth of Cities in the Nineteenth Century . . .* (1899; 1963 ed.), pp. 162-165; Dovring, "The transformation of European agriculture" (1965).

<sup>405</sup> Saville, *Rural Depopulation . . .* (1957), p. 2.

<sup>406</sup> *Ibid.*, p. 5.

<sup>407</sup> Horstmann, "Rural-urban migration . . ." (1967), p. 496; Dovring, "The transformation of European agriculture" (1965), pp. 604-605. Dovring has also noted (pp. 633-634) that the spread of the potato (a crop with a high caloric yield per acre and a high labour input required per acre) in Scandinavia and many parts of the Continent, mostly during the first half of the nineteenth century, permitted a greater rural population density and represented a postponement of a Malthusian check on population growth.

<sup>408</sup> Saville, *Rural Depopulation . . .* (1957), p. 14; Weber, *The Growth of Cities in the Nineteenth Century . . .* (1899; 1963 ed.).

189. In general, the governments of the industrializing countries adopted tariff, taxation, monetary and other policies that promoted trade and manufacturing and strengthened the demand for labour in these sectors.<sup>409</sup> In England the enclosure acts, which resulted in "the consolidation of small farms into large", drove labourers off the land by depriving them of their vital "rights of pasturage for sheep and geese on common lands".<sup>410</sup> With the opening up of the farm lands of the New World, "the agricultural systems of Europe entered upon a highly critical phase".<sup>411</sup> The competition was especially severe in the cultivation of grain. Most countries reacted by converting arable land to the production of dairy produce and meat and by the adoption of mixed farming using labour-intensive methods of production and spreading the labour load over the year so as to absorb the available labour as completely as possible;<sup>412</sup> most countries also put up their tariff barriers.<sup>413</sup> In England, for example, the impact of falling prices was much greater upon the grain farmer than upon the meat and dairy farmer.<sup>414</sup> Notable also in all countries was the divorce of industry from the village and the decline of the rural craftsman and of rural industries in general, in part due to stagnant or declining population, but more significantly to the competition of goods manufactured more cheaply on a large scale in urban centres.<sup>415</sup> Another factor was the tendency towards administrative centralization with the transfer of duties from local to central authorities and of governmental machinery from the small locality to the large city.<sup>416</sup> Migration to a large city was often a complex process with the central city drawing population especially from nearby rural areas and from smaller cities and towns whose population was in turn partly replaced by agricultural migrants from distant rural places.<sup>417</sup>

190. The expansion of labour demand in urban areas was heightened by the slower or even negative rate of natural increase of population in the cities.<sup>418</sup> The growth of employment opportunities was not confined to unskilled

labour in workshops and factories, but embraced also construction, trade and related services with a demand for a wide variety of skills, both manual and white-collar. At this stage of industrial capitalism, most enterprises were small in scale so that the individual worker or employee could often with some degree of realism aspire by frugal living to accumulate enough capital to start his own workshop or business.<sup>419</sup> Furthermore, the deterioration of rural employment opportunities and the corresponding expansion of the urban sector was accentuated by the newly established international division of labour whereby colonial populations and non-industrial independent countries became profitable markets for manufactured goods in exchange for a supply of food products and raw materials.<sup>420</sup> The domestic market did not provide an ample base for the rapid industrial expansion that was taking place at this time. Although wages (and apparently incomes also) were substantially higher in urban centres,<sup>421</sup> this was before the era of the mass consumption economy, and the bulk of the working population in both urban and rural areas did not live at much above the subsistence level.

191. The economic history of the overseas areas of European settlement differed from that of Europe. Such countries as Australia, Canada, New Zealand and the United States of America at first shared with the less developed regions the role of exporters of primary goods, but at the same time they also made rapid strides in industrialization and urbanization. This was accomplished by different means in each instance. In the United States such development became possible because (a) agricultural expansion was based on a relatively wide distribution of land tenure,<sup>422</sup> which permitted the development of a substantial domestic market; and (b) the Government promoted a vigorous policy of industrialization by means of tariff protection against the competition of European manufactured goods. In all four countries, immigrant labour from Europe participated both in the agricultural expansion as well as in the industrial enterprises. As a result of their rapid development, fertility in these countries declined around the turn of the century, as it had in Europe, until it reached a point at which the natural increase of population in rural areas no longer exceeded the rural out-migration to urban

<sup>409</sup> Weber, *The Growth of Cities in the Nineteenth Century*... (1899; 1963 ed.), pp. 213-215.

<sup>410</sup> *Ibid.*, pp. 165-166.

<sup>411</sup> Medina Echavarría and Hauser, "Rapporteurs' report" (1961), p. 40.

<sup>412</sup> Dovring, "The transformation of European agriculture" (1965), pp. 634, 638; International Labour Office, *Why Labour Leaves the Land*... (1960), p. 193; Cole and Deane, "The growth of national incomes" (1965), pp. 12-14.

<sup>413</sup> Youngson, "The opening up of new territories" (1965), pp. 170-174.

<sup>414</sup> Saville, *Rural Depopulation*... (1957), p. 14.

<sup>415</sup> Horstmann, "Rural-urban migration..." (1967), p. 496. See also Saville, *Rural Depopulation*... (1957), pp. 20-30, for an account of the types of craftsmen and small-scale rural industries in England before the centralization of production that accompanied the spread of the factory system and how they gradually withered away.

<sup>416</sup> Weber, *The Growth of Cities in the Nineteenth Century*... (1899; 1963 ed.), p. 215.

<sup>417</sup> According to Weber's analysis of the data from several European countries, only a small proportion of the total in-migrants to large cities came from remote rural places. However, his data seem to indicate that most out-migrants from remote rural areas did not move by stages to the large city. *Ibid.*, pp. 267 and 270.

<sup>418</sup> See section C above.

<sup>419</sup> Bairoch, among others, has examined how this situation favoured the emergence of a capitalist class drawn in no small part from humble social strata and especially from the countryside and from agriculture. The rural origin of textile industrialists was particularly noticeable. Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 118, 205.

<sup>420</sup> Ferns, *Britain and Argentina*... (1960), p. 14; Singer, *International Development: Growth and Change* (1964), p. 168. Bairoch has gathered data on trends in foreign trade for England and France which enable him to argue convincingly that export markets could not have been a very significant factor in the economic growth of these countries prior to the last few decades of the nineteenth century. Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 258-265, 331-340.

<sup>421</sup> See Saville, *Rural Depopulation*... (1957), pp. 13-20, for an examination of urban-rural wage and earnings differentials in England before the First World War.

<sup>422</sup> Except for the cotton industry in the South which was relegated to a subordinate role in that nation's economic growth after the Civil War (1861-1865).

areas. Thus, with the completion of the last phase of the demographic transition, the decline of the rural population became absolute as well as relative.

192. In two Latin American countries—Argentina and Uruguay—economic growth was somewhat parallel to that in the four countries of North America and Oceania mentioned above. Although land ownership was more concentrated than in the United States, immigrant tenant farmers and some immigrant owners participated in the prosperity of economic expansion and a substantial domestic market developed. However, the Government of Argentina, reflecting the interests of large landowners, adhered strictly to its role in the international division of labour and discouraged the manufacture of whatever could be imported from Europe.<sup>423</sup>

## (ii) Socio-cultural determining factors

193. Various factors affecting socio-cultural conditions differentially in rural and urban areas are mentioned in the literature as having had a contributing influence upon rural-urban migration. The conditions most frequently referred to are educational opportunities, health services and conditions, the quality of housing, public service facilities (water supply, gas, electricity, telephone etc.), cultural and recreational opportunities (theatre, movies, libraries, newspapers and other mass media), and social legislation concerning working conditions, public welfare and relief programmes. Many of these differences were in a continuous state of evolution. Generally, however, educational opportunities were inferior in rural areas with the possible exception of village education at the primary level.<sup>424</sup> Although urban centres had usually become self-replacing in the sense of having a positive rate of natural increase, urban health conditions in terms of either infant mortality or life expectancy apparently remained inferior to the rural until well into the twentieth century.<sup>425</sup> In this, as well as in some other respects, conditions in urban areas were often discouraging at first,<sup>426</sup> but they gradually improved and eventually added to the factors of attraction. For those rural residents who were not unskilled manual labourers and especially those who could move at least into lower middle-class urban occupations, the socio-cultural conditions of city life had decidedly more to offer.

<sup>423</sup> Ferns, *Britain and Argentina* . . . (1960); Ferrer, *La economía argentina* . . . (1963), pp. 91-152. The intermediate status of Argentina and Uruguay between the more developed and less developed countries is reflected in Germani's characterization of them as modernized, although insufficiently developed. Germani, *Política y sociedad* . . . (1968), p. 223.

<sup>424</sup> Weber, *The Growth of Cities in the Nineteenth Century* . . . (1899; 1963 ed.), p. 218.

<sup>425</sup> See section C above; also chapter V, section E on rural and urban mortality conditions in the developed countries.

<sup>426</sup> Buchanan and Ellis, commenting upon the appalling conditions associated with the occupational and geographical redistribution of the labour force, observe that "usually the growth of cities was so rapid that overcrowding, bad sanitation and a generally unhealthy environment was inevitable. Moreover, during much of the nineteenth century, governments had no previous experience with such urban concentrations and the social costs they entailed and therefore had no knowledge of how to deal with them". Buchanan and Ellis, *Approaches to Economic Development* (1955), p. 411.

## (iii) Facilitating and precipitating factors

194. In the literature, frequent reference is also found to other factors affecting migration that are less basic and, either implicitly or explicitly, are regarded as facilitating or precipitating factors. One such factor is the freeing of labour from the attachment or bondage to the soil characteristic of most agricultural societies with a heritage of feudalism and with relatively self-sufficient local and provincial markets. The development of industrial capitalism required the free movement of the inputs of production (labour and capital) and its outputs in the national market.<sup>427</sup> Not only did internal taxes and tolls on the movements of goods have to be abolished, but also "medieval restrictions had to be swept away to secure freedom of migration and domicile" in Europe.<sup>428</sup> Technological progress in transportation (first, the construction of canals, then the railroad and later the automobile and the airplane) was described by one writer as an accelerating, rather than an initiating factor.<sup>429</sup> Associated with this were improved communication methods which permitted migrants to share with their kinfolk and friends in the areas of origin information about opportunities and conditions of living in the urban places of destination. This flow of communication between place of origin and place of destination also made possible the formation of organization networks, either on a kinship or entire community basis, which helped migrants find jobs and often offered them temporary shelter until they could get settled.<sup>430</sup> Another facilitating factor was the urban type of education often provided in rural schools which gave children better training for urban occupations than for agricultural work.<sup>431</sup>

<sup>427</sup> Adam Smith observed that "whatever obstructs the free circulation of labour from one employment to another, obstructs that of stock likewise. . . . The obstruction which corporation laws give to the free circulation of labour is common, I believe, to every part of Europe". Smith, *An Inquiry into the Nature* . . . (1776; 1966 ed.), p. 135.

<sup>428</sup> Weber, *The Growth of Cities in the Nineteenth Century* . . . (1899; 1963 ed.), pp. 214-215, notes the modification of the English law of settlement in 1795 and the abolition of serfdom in Prussia in 1808. Gerschenkron sees the rapid industrialization of the 1890s in Russia, where liberation from the soil began with formal emancipation in 1861 and was not really consummated until the Acts of 1906 and 1910, as a refutation of the widely accepted supposition that agrarian reform is a major prerequisite of modern industrialization. Gerschenkron, "Agrarian policies . . ." (1965), pp. 712, 798-799. Several other writers have commented that a migratory movement, once established on a massive scale, moves out of a sort of inertia and imitation similar to the inertia of pre-industrial attachment to the soil. Mortara, "Factors affecting rural-urban migration . . ." (1967), p. 512; Petersen, *Population* (1961), p. 607. In this sense the pioneering efforts of the early migrants facilitated the movement of those who came later.

<sup>429</sup> Saville, *Rural Depopulation* . . . (1957), p. 10.

<sup>430</sup> Germani, "Migration and acculturation" (1964), p. 175; Sjöberg, "Rural-urban balance . . ." (1966), pp. 244-245; Brown, Schwarzweller and Mangalam, "Kentucky mountain migration . . ." (1963).

<sup>431</sup> United Nations, *Report on the World Social Situation* . . . (1957), p. 170; Mortara, "Factors affecting rural-urban migration . . ." (1967), p. 512; Herrick, *Urban Migration* . . . (1965), p. 37.

(i) *The presently more developed countries*

195. Rural-urban migration and especially the movement out of agriculture has continued unabated in western countries in the twentieth century. Beginning around the middle of the nineteenth century in a few countries, although not until the twentieth century in most countries, the agricultural labour force has been declining in absolute numbers as well as in proportion to the total labour force; furthermore, this decline has greatly accelerated in the years following the Second World War.<sup>432</sup> The principal economic factors have continued to be increased agricultural efficiency and the shift in labour demand from agriculture to the secondary and tertiary sectors in the cities.<sup>433</sup> One difference is that the conversion from steam to electric energy has permitted the dispersal of industry to less populated urban areas, or to wider metropolitan regions.<sup>434</sup>

196. In the United States, early internal migration represented a process of dispersion of population towards rural areas of attractive physical resources, but by the 1920s migration trends reflected the concentration of population around a small number of industrial centres.<sup>435</sup> The South was the area of heaviest out-migration, owing to the mechanization of agriculture as well as other conditions affecting farm labour demand in that region.<sup>436</sup> Recent decades have seen an increasing concentration of industry in the coastal areas while the economic basis of the agricultural interior has been deteriorating.<sup>437</sup> Over a long period, internal migration responded positively to decadal swings in economic activity, increasing in periods of prosperity and decreasing during depressions.<sup>438</sup> Studies aimed at distinguishing the influence of differentials in levels of living and income on migration have generally shown a high positive correlation, although during certain periods and for certain types of movements there have been exceptions.<sup>439</sup>

<sup>432</sup> Dovring, "The transformation of European agriculture" (1965), pp. 611-613. Of course the volume of the migratory stream has necessarily shrunk as the rural-agricultural population base has become smaller. See also chapter IX, section D, and chapter XIV, section B.

<sup>433</sup> For a discussion of the factors affecting shifts in the structure of production in the United States, see Kuznets, "Introduction: Population redistribution, migration ..." (1964), pp. xxv-xxvi.

<sup>438</sup> Eldridge and Thomas, *Population Redistribution* ... (1964), particularly pp. 333, 345, 368. See also Thomas and Zachariah, "Some temporal variations in internal migration ..." (1963).

<sup>439</sup> See, for example, Spengler, "Migration within the United States" (1936), pp. 8-9; Bogue, *Components of Population Change* ... (1957), pp. 24-29; and his *The Population of the United States* (1959), pp. 416-417; Eldridge and Thomas, *Population Redistribution* ... (1964), particularly pp. 353, 366-368; Thomas, "Internal migration in the United States ..." (1967), p. 536.

197. During the last decades of the nineteenth and the first decades of the present century, socio-cultural conditions improved markedly with the acquisition of leisure as an item of social living. Social legislation shortened the work day and lengthened the weekend, improved street lighting and sewage disposal made cities safer and healthier places to live in; and facilities for the enjoyment of leisure were developed. Educational opportunities were improved and social security programmes were adopted. Many of these changes were introduced first in the cities, to the relative exclusion of the countryside which then appeared as cultural abysses manifestly backward and outside the mainstream of life.<sup>440</sup> There is reason for thinking that socio-cultural push and pull factors assumed greater importance during this period. Temporary moves from the home community to places offering higher education tended to facilitate long-term migration, as persons once freed from social and family ties were potentially more mobile. Demographic factors also played a role, since rural areas have generally been found to have higher rates of natural increase than urban areas, with the result that the requirements for internal migration generated by shifts in industrial structure have been magnified.<sup>441</sup>

198. Since the Second World War, such developments as rural electrification and the popularization of the automobile have diminished the social and cultural differences between modernized rural areas, small and large cities, and over-crowdedness has detracted from the attractiveness of the great cities.<sup>442</sup> Commuting has severed the hitherto necessary relation between place of work and place of residence, and as a result, residential considerations have been growing in importance at the expense of economic factors, especially in the case of short-distance migration.<sup>443</sup> The lengthening of the

<sup>440</sup> Saville, *Rural Depopulation* ... (1957), pp. 30-37. On some of the changes which occurred in twentieth century cities, see also Hauser, "Urbanization—problems of high density living" (1968), p. 197.

<sup>441</sup> Kuznets, "Introduction: population redistribution, migration ..." (1964), pp. xxvii-xxviii. On the relationship between levels of natural increase and net migration see also Vance, *Research Memorandum* ... (1938), pp. 55, 101; Lee, "Internal migration ..." (1964), p. 125; Thomas, "Internal migration in the United States ..." (1967), p. 534; and Bogue, *The Population of the United States* (1959), p. 403. See also Hamilton, "Population pressure ..." (1956).

<sup>442</sup> Saville, *Rural Depopulation* ... (1957), p. 36; Germani, "Migration and acculturation" (1964), p. 169; International Labour Office, *Why Labour Leaves the Land* ... (1960), pp. 26, 117. Furthermore, government assistance has improved the position of agriculture in some of the advanced countries. Because of price and income support policies to raise farm prices, farmers' incomes are much higher in relation to incomes in other occupations than they were in the interwar years.

<sup>443</sup> In a study of internal migration in the Netherlands during the period 1948-1960, Ter Heide found a ratio of 41 to 24 between the influence of economic and residential factors. Comparing net migration during the periods 1951-1955 and 1956-1960 he found a decline of net out-migration in rural municipalities which he attributed to an increase in commutation among people already resident in rural areas because the flow of workers from agriculture intensified during this period. A somewhat similar explanation appears to account for decreasing net in-migration in large cities. Ter Heide, "Some aspects of internal migration ..." (1968), pp. 149-150.

years of life after retirement, increasing financial security of older persons, and changing family structure are developments believed to be conducive to a greater mobility of the retired population.<sup>444</sup>

199. Two large countries which began their industrialization much later than did the other presently developed countries are the Soviet Union and Japan. Deliberate economic planning has assumed a greater importance in both of these countries than it did in the countries which developed earlier, although the types of planning measures adopted in the two countries have been very dissimilar.<sup>445</sup>

200. Migration has been both a product and a precondition of the development of the Japanese industrial economy.<sup>446</sup> Despite the fact that Japan followed its own distinctive style in developing into a modern urbanized society, the underlying forces which brought a huge volume of migration from rural to urban areas are similar to those observed in Western Europe and the areas of overseas European settlement. The principal determinants of this migration were economic in nature; they included the continuous creation of employment opportunities in urban and metropolitan industries, and the existing disparities of levels of living between urban and rural areas, or between more industrialized and less industrialized prefectures.<sup>447</sup> From the beginning of industrialization in the late nineteenth century, industries were founded in the central regions of the Pacific Seaboard, such as Tokyo, Osaka and Nagoya, which occupied strategic locations in terms of space economy and geography. Other industries were attracted to these cities by the promise of external economies, and a snow-ball effect was generated. The economies of these great cities and their satellites were able to easily absorb the surplus labour force pushed out of the rural areas.<sup>448</sup> The almost constant numbers of the agricultural population, as well as agricultural workers, in the pre-war era<sup>449</sup> showed

that the surplus rural labour force had been siphoned off by the pull of the urban-industrial area.<sup>450</sup>

201. In the Soviet Union, although various kinds of incentives have been offered to persons willing to settle in sparsely populated areas east of the Urals (see section B above), the fact that opportunities are relatively better in cities than in most rural areas has resulted in a large flow of migration to cities from the rural areas.<sup>451</sup> The emphasis in government strategy in the past has not been to stem the flow of migration to all cities, but mostly to restrict the growth of the largest cities.<sup>452</sup> Restrictions have been difficult to implement, however, and it is anticipated that the number of cities of 1 million or more inhabitants will increase considerably during the next decade or so.<sup>453</sup> According to Valantei and Khorev, bans on new enterprises are often circumvented by undertaking new construction under the guise of extending and reconstructing existing enterprises situated in large cities. Administrative restrictions on residence in large cities have also been found to have unintended effects, since they dissuade some pensioners, who might otherwise move away from large cities after their retirement, from leaving, for fear that if they changed their minds, they would be prevented from returning.<sup>454</sup>

#### (ii) *The presently less developed countries*

202. In many of the presently less developed countries there is purported to be a "push" effect exerted upon rural inhabitants to migrate where they might be more productive.<sup>455</sup> There frequently exists an excess of rural population in relation to the land cultivated, resulting in much under-employment. In these circumstances, a decrease in the farm population may not reduce output, but may even increase it by permitting more efficiently organized production through larger-scale capital intensive farming operations.<sup>456</sup> There is often much indebtedness, while there is little cash-earning employment. Where rural poverty and under-employment are severe,

<sup>444</sup> Kuznets, "Introduction: population redistribution, migration..." (1964), p. xxviii.

<sup>445</sup> The Government of Japan, beginning with the Meiji Restoration of 1868, pursued a vigorous, long-range policy of very rapid industrialization. Levy, "Contrasting factors in the modernization..." (1955), p. 527; Allen, "The industrialization of the Far East" (1965), p. 909. Effective economic planning in the Soviet Union began half a century ago. USSR, Tsentralnoe Statisticheskoe Upravlenie pri Sovete Ministrov SSSR, *Strana Sovetov za 50 let...* (1967).

<sup>446</sup> Taeuber, *The Population of Japan* (1958), p. 123.

<sup>447</sup> Saito and Kobayashi, "Sengo ni okeru wagakuni kokunai jinko..." (1967), pp. 188-190, 232-234; Tachi, *Jinko Mondai no Chishiki* (1969), pp. 167-168; Okazaki, *Nihon no Rodoryoku Mondai* (1966), pp. 131-133; Umemura, *Chingin, Koyo, Nogyo* (1961), p. 198.

<sup>448</sup> See, for example, Nojiri, "Nihon ni okeru..." (1954). Compared to conditions in many parts of South Asia at present, the rate of natural increase in Japan was never very high. It was under 1.4 per cent per annum even during the early decades of the twentieth century. Tachi, *Jinko Mondai no Chishiki* (1969), p. 98. Moreover, urban-rural differences in the rate of natural increase have not been very great; between 1920 and 1940 the rate seldom exceeded 16 per thousand in rural areas, while in urban areas it was estimated to be between 10 and 12. See Japan, Institute of Population Problems, *Zenkoku Shibu-gunbu...* (1968), p. 16.

<sup>449</sup> Namiki, "Sengo ni okeru nogyo jinko..." (1958).

<sup>450</sup> Minami, "Rodoryoku no hendo" (1964). Minami showed that rural-urban migration in Japan during this period was closely related to the supply of surplus labour in rural areas and the demand for labour in secondary and tertiary industries in urban areas. He found a significant statistical relationship between the volume and rate of rural-urban migration and the business cycle.

<sup>451</sup> Valantei and Sorokina, *Naselenie, trudovye resursy SSSR...* (1971), pp. 210-216.

<sup>452</sup> See, for example, Khorev, "Kakoi gorod nuzhen?" (1969), and his *Gorodskie poseleniia SSSR...* (1968).

<sup>453</sup> Svetlichny, "Gorod zhdet otveta" (1966). For a discussion of the economic and social factors which will ensure the future population growth of large cities, see Perevedentsev, "Goroda i gody" (1969). Selyunin has observed that it is precisely the restricted cities in the Soviet Union that attract the most new settlers. Selyunin, "Trud nash nasushchnyi" (1967).

<sup>454</sup> Valantei and Khorev, "Problemy gorodov" (1966). Migration to cities where construction of industrial enterprises has been prohibited appears to continue despite restrictions. A table showing the volume of expected migration to eighteen such cities during the period 1966-1980 is shown in Mkrtchyan, "Metodologicheskie voprosy razmeshcheniia proizvoditelnykh sil" (1969).

<sup>455</sup> The "push" effect in these countries is considered by many authors to be of greater importance than the forces of urban attraction. See, for example, Beaujeu-Garnier, "Large overpopulated cities..." (1970), p. 269.

<sup>456</sup> See Leibenstein, *Economic Backwardness and Economic Growth* (1957), pp. 58-76. See also chapter XIII, section C.

there may develop a strong belief that the economic conditions of urban areas are more promising, provoking city-ward migration.<sup>457</sup>

203. Even in those instances in which technological progress in agriculture (such as improved equipment, seeds, fertilizers, and working methods) has increased the productivity of both land and labour, a distortion often occurs in the relationship between the rural and urban sectors. While the improvements eventually reduce the need for agricultural labour and provide an increased output capable of supporting more people, in many contemporary examples the urban economies are not expanding rapidly enough to generate productive employment opportunities on a sufficient scale, and rural-urban migration exceeds the absorptive capacity of the cities.<sup>458</sup>

204. The situation is substantially different from that which accompanied urban growth in the presently developed nations. The urban and rural economies in many developing countries, rather than being related to each other, are often closely identified with activities within the highly industrialized countries.<sup>459</sup> This is reflected in a poorly integrated national economy and excessive urban growth.<sup>460</sup> This outward-looking orientation in many developing countries is a legacy of their colonial history, but even those developing countries which were not subject to colonial administration show many of the same tendencies owing to the fact that the system of international trade was dominated by the major industrial and commercial powers of the time who fostered arrangements designed to gain the greatest commercial advantages for themselves. Major port cities in the less developed countries concentrated on the functions of shipment and handling of exports, mostly raw materials, and imports, mostly finished goods. Industrial processes for the transformation of raw materials appeared in later phases of development, mostly in a subordinate role.<sup>461</sup> Many of these patterns persisted in the less developed countries even after the attainment of political independence, and a "dual economy", characterized by a modern sector including a large capital city on the one hand, and an impoverished rural hinterland on the other, has resulted.<sup>462</sup>

<sup>457</sup> The "push-pull" hypothesis of migration is a classical explanation of the phenomenon and is discussed later in this section.

<sup>458</sup> See the discussion in chapter IX, section E and chapter XIII, section C.

<sup>459</sup> See, for example, Hauser, "Urbanization—problems of high density living" (1968), p. 203.

<sup>460</sup> For a discussion of how the notions of classical economics have affected the structure of under-developed countries see Frank, *Capitalism and Under-development in Latin America* (1967).

<sup>461</sup> A study of the United Nations Economic Commission for Asia and the Far East notes that during the "commercial" phase of Asian urbanization, which can be related to the colonial period, trade cities began to develop along the coasts and gradually became the focal points for the collection, storage, handling and distribution of exports and imports. Later the processing of raw materials from the hinterland was added to the activities of these centres. See "Economic causes and implications of urbanization ..." (1957), pp. 140-141. See also Murphey, "Urbanization in Asia" (1969). For a discussion of similar patterns in Africa see Mobogunje, *Urbanization in Nigeria* (1968), pp. 107-171.

<sup>462</sup> On the concept of "dual economy" see Boeke, *Economics and Economic Policy of Dual Societies* ... (1953). For further discussion see chapter XIII, section D.

205. The economic relationships described above had a profound effect upon the manner in which urbanization progressed, and urban conditions as observed in many developing nations have been described by the controversial term "over-urbanization". This term has often been used to describe a situation where a country has a larger urban population than seems justified by its levels of industrialization.<sup>463</sup> Some writers have objected, however, that this conclusion is based on the experience of the countries which had developed earlier and that western models for development are not necessarily valid for the rest of the world.<sup>464</sup>

206. A comprehensive international study of rural-urban migration undertaken by the International Labour Office pointed to similarities in the determinants of migration in the more developed and less developed countries, but noted markedly different conditions under which these determining factors operate in the two groups. The report stated that "... the factors determining movement are the same in all countries, namely relative incomes in agriculture and other occupations, employment opportunities, and a variety of social and institutional disadvantages affecting agricultural workers and the rural community. 'Push' and 'pull' vary in strength in different conditions but, to a greater or lesser extent the same factors are universally operative."<sup>465</sup> On the other hand, the conditions within which these push and pull factors operate in Africa, Asia and Latin America were found to be basically different from those of North America, Oceania and Western Europe in the past century.<sup>466</sup> The most notable difference is the questionable causal relationship in the developing countries today between change in occupational structure and economic growth. This difference is the basis for the conclusion of certain scholars, as noted above, that many developing countries are "over-urbanized" in relation to their low levels of industrialization.<sup>467</sup>

<sup>463</sup> The term was suggested by Davis and Hertz Golden, "Urbanization and the development of preindustrial areas" (1954). See also Hauser, "Urbanization—problems of high density living" (1968), pp. 203-204; Breese, *Urbanization in Newly Developing Countries* (1966), pp. 134-136. Friedmann and Lackington used "hyperurbanization" to denote a similar concept. See their "Hyperurbanization and national development in Chile ..." (1967). For contrary views see Sovani, "The analysis of 'over-urbanization'" (1964) and Kamerschen, "Further analysis of overurbanization" (1969). See also the discussion of over-urbanization in chapter XIV, section C.

<sup>464</sup> See, for example, Abu-Lughod, "Urbanization in Egypt ..." (1965).

<sup>465</sup> International Labour Office, *Why Labour Leaves the Land* ... (1960), pp. 182-183. See also Kosiński and Prothero, "Migrations and population pressures ..." (1970), p. 252. The findings of the ILO study appear to be consistent with the results of various local studies. For example, Schultz found differential incomes in urban and rural areas to be an important factor in internal migration in Colombia between 1951 and 1964. See his "Rural-urban migration in Colombia" (1971), p. 163. See also Piplai and Majumdar, "Internal migration in India ..." (1969), p. 512.

<sup>466</sup> International Labour Office, *Why Labour Leaves the Land* ... (1960), pp. 182-183.

<sup>467</sup> Germani observed that mass migration may occur even when stimulated only slightly, if at all, by urban industrial growth. Germani, "Migration and acculturation" (1964), p. 160. Medina Echavarría and Hauser speak of "urbanization without economic development". See their "Rapporteurs' report" (1961), p. 37. Herrick suggested "a model in which the urban migration is not

Nevertheless, the International Labour Office survey found the volume of rural-urban movement to be much larger in those countries that were rapidly industrializing and in which the demand for non-agricultural labour was, in fact, increasing.<sup>468</sup>

207. Even in the more industrialized of the less developed countries, migration cityward generally is well in excess of economic growth as there is an insufficient expansion of labour demand. Friedmann and Herrick, for instance, have commented upon continued rural-urban migration despite high levels of urban unemployment in Venezuela and Chile, respectively.<sup>469</sup> These differences, the rural economic stagnation and insufficient expansion of urban demand for labour, have received some attention in the migration literature and various explanations have been proposed. Some writers have suggested the greater relevance in the present-day context of many non-economic causes of dissatisfaction with the rural environment or attraction to the cities.

208. Among the explanations advanced for rural backwardness have been: (a) land tenure systems in which large estates obtain a secure income by extensive use of land for livestock grazing;<sup>470</sup> (b) official economic development policies emphasizing industrialization almost to the exclusion of agriculture;<sup>471</sup> (c) the specialization of agriculture in many of the less developed countries during the second half of the nineteenth century in export crops whose markets in the advanced countries have subsequently ceased to expand and whose profitability has diminished further because of a deterioration in the terms of trade.<sup>472</sup>

209. The inadequate labour-absorptive capacity of industrialization in even the most rapidly developing countries has been explained partly in terms of the highly capital-intensive nature of modern industry in which

such a clear sign of well-being in the economy". Herrick, *Urban Migration* ... (1965), p. 2.

<sup>468</sup> International Labour Office, *Why Labour Leaves the Land* ... (1960), pp. 16-17, 144.

<sup>469</sup> Friedmann, *Regional Development Policy* ... (1966), pp. 32-33; Herrick, *Urban Migration* ... (1965), pp. 69-70. In Friedmann's opinion migration continues until urban unemployment reaches a certain critical level which "appears to depend on the extent of rural misery and is reached in many under-developed economies at about 15 per cent".

<sup>470</sup> Mortara, "Factors affecting rural-urban migration ..." (1967), p. 510; Medina Echavarría and Hauser, "Rapporteurs' report" (1961), p. 35.

<sup>471</sup> Mortara, "Factors affecting rural-urban migration ..." (1967), p. 512; Smith, *Latin American Population Studies* (1960), p. 60; Sjöberg, "Rural-urban balance ..." (1966), p. 246; United Nations, *Report on the World Social Situation: with Special Reference* ... (1961), p. 21; United Nations, *Report on the World Social Situation* ... (1957), p. 171.

<sup>472</sup> Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 187-188; Mortara, "Factors affecting rural-urban migration ..." (1967), p. 510. Bairoch observes (pp. 186-187) that this specialization was usually in industrial (non-alimentary) export crops and involved a type of plantation agriculture whose techniques were not readily transferrable to traditional agriculture which remained technologically backward. Many of these countries used their export surplus to import food products as well as manufactured products.

employment has grown more slowly than output,<sup>473</sup> and partly as a function of the restricted market available for its products<sup>474</sup> so that operation at capacity, in order to take advantage of economies of scale, is not feasible. However, various sources have pointed out that although investment in modern industry is not very productive of employment in manufacturing itself, urban employment expands more as a result of the need for services connected with manufacturing (banking, communications and transportation, advertising, maintenance and repair etc.).<sup>475</sup> In part because of the present structure of international trade, the expansion of manufacturing in developing countries has to contend with the obstacle of limited production for a highly protected and narrowly based domestic market, whereas the industrializing countries of the late nineteenth century, during their peak period of population growth, were able to count on a relatively flourishing rural market and also to tap the markets of their colonies (or expanding frontiers) and of relatively backward countries.<sup>476</sup>

210. Certain aspects of these differences in the relationship of rural-urban migration to economic growth are of special demographic interest. The historical experience of the less developed countries in the integrated world market that emerged in the second half of the nineteenth century has been mentioned as having contributed to cumulative population pressure in several ways. The destructive impact of imported manufactured goods on village crafts and small-scale industries owing to the newly established international division of labour has been often noted, especially with respect to India.<sup>477</sup> Davis has shown how British relations with India initiated

<sup>473</sup> United Nations, *Report on the World Social Situation* ... (1957), p. 126. It has also been noted that the developing countries today, in their efforts to accelerate the process of industrialization, are frequently relying on imported capital equipment and even raw materials. The indirect or secondary creation of employment opportunities under this form of production is much less than in more integrated economies. Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 180-181; Ferrer, *La economía argentina* ... (1963), part 4, pp. 155-235.

<sup>474</sup> Nun, "Superpoblación relativa, ejército industrial ..." (1969), pp. 206-207, 215; Singer, *International Development: Growth and Change* (1964), p. 162-164.

<sup>475</sup> Mortara, "Factors affecting rural-urban migration ..." (1967), p. 511.

<sup>476</sup> A United Nations report observed that "in nineteenth century Europe, industry produced for a world market in which little competition existed; the manufacturers of the newly industrializing countries may find international markets well-stocked with competing goods of the industrialized countries ...". United Nations, *Report on the World Social Situation* ... (1957), p. 129.

<sup>477</sup> Myrdal, *Asian Drama* ... (1968), vol. 2, chap. 25; Allen, "The industrialization of the Far East" (1965), pp. 908-909; Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 174-175; Ferrer, *La economía argentina* ... (1963), part 4, pp. 82-83. The decline of rural crafts and industries in the face of competition from machine-made manufactured goods occurred also in the industrializing countries of the nineteenth century. The crucial difference is that in the present instance the manufactured goods were imported from the industrialized countries. Because there was generally a prolonged "lacuna between the collapse of the older industries and the rise of" new ones (Allen, pp. 908-909 describing India's experience), the place of the eliminated jobs was taken by newly created jobs in other countries. In other words, the rural "push" factor was not being generated to the accompaniment of a corresponding urban "pull" factor.

a decline in mortality and Arriaga's study of historical trends of mortality in Latin America indicates that many if not most of the countries in this region had declining mortality during this period.<sup>478</sup> The greatest demographic significance of this one-sided economic development is that it was not associated with those changes in the social structure which would have laid the groundwork for a decline in fertility. As a consequence of continued high fertility and rapid declines of mortality, population in the less developed regions is now growing at unprecedented rates. In contrast to the situation that prevailed in the advanced countries during the nineteenth century, there is some evidence to suggest that the rate of natural increase may be of comparable magnitude in urban and rural areas.<sup>479</sup> Urban natural increase may thus to a considerable extent satisfy the increased demand for urban manpower created by economic growth.<sup>480</sup> Moreover, the pressure resulting from the natural growth of population is unalleviated by the emigration escape valve that was available to the countries of Western Europe during their phase of maximum population growth.<sup>481</sup> One analyst has found evidence not only of a rural population push factor, but also of an urban population "push-back" factor.<sup>482</sup> Other studies of internal migration in India explain the decline of migration to the cities during the 1951-1961 period mainly in terms of the faster urban rate of natural increase which may have left less room for migrants in the absence of corresponding growth of opportunities.<sup>483</sup> In Latin America the excess population is increasingly being characterized as a "marginal population" accumulating at the peri-urban fringes, and various

studies of this question have been made or are in process.<sup>484</sup>

211. Aside from pressures arising in the rural areas, the urban localities gain in relative attractiveness also for various other reasons. As the countryside in some regions suffers the loss of its non-farm industry and the cities become "more 'modern' in their patterns of consumption than in their patterns of production",<sup>485</sup> society to some extent becomes polarized into a modernized urban sector and a traditional rural sector.<sup>486</sup> The influence of socio-cultural factors of this kind is mentioned especially in the literature on rural-urban migration in Latin America.<sup>487</sup> The proximity to cultural features enjoyed by some in the city, however, constitutes for most migrants a strictly psychological satisfaction. Many of these superior urban conditions are not accessible to migrant workers of little economic skill.<sup>488</sup> But these psychological attractions are seldom fully revealed in sociological surveys. As a rule, most migration surveys indicate that economic factors are salient<sup>489</sup> and writers generally assume that for the majority of migrants socio-cultural factors are secondary or ancillary to the basic economic considerations.<sup>490</sup>

212. With due regard for the many differences within each region, rural-urban migration in Asia, and even more so in Africa, reflects the more retarded character of urbanization and of economic development in these regions as compared with Latin America. Educational development is less advanced,<sup>491</sup> as also are legislative provisions for social security and labour protection.<sup>492</sup> In India, "health conditions, though bad in the villages, are worse in the cities, and the migrants themselves are

<sup>478</sup> Davis, *The Population of India* ... (1951), pp. 38-42; Arriaga, *New Life Tables* ... (1968). Confirmation of mounting population pressure at this time in India and China is found in the emigration movements overseas and to neighbouring countries described in chapter VII. There was also much internal migration in India to the estate regions of the north-east and south-west where the export crops were being produced. Davis, *The Population of India* ... (1951), pp. 114-117.

<sup>479</sup> See the discussion in section C above. See also Arriaga, "Components of city growth ..." (1968); Davis, "The urbanization of the human population" (1965), pp. 48-51; Kuroda, "Internal migration ..." (1967), p. 505; Bose, "Internal migration in India ..." (1967), pp. 483-486.

<sup>480</sup> Contrasting conditions in Europe in the nineteenth century with those in India at present, Mitra emphasized the low rate of natural growth in European cities which was inadequate to meet growing labour demands. See his "Problems of internal migration ..." (1968), pp. 8-9.

<sup>481</sup> Easterlin, "Influences in European overseas emigration ..." (1961), pp. 331-351.

<sup>482</sup> Bose, "Internal migration in India ..." (1967), p. 484.

<sup>483</sup> Rele, "Trends and significance of internal migration ..." (1969), p. 505; Zachariah and Ambannavar, "Population redistribution in India ..." (1967), p. 105. The latter authors also considered that the pattern of India's development programme may have caused a structural change in internal migration, whereby urban-to-urban and rural-to-rural movements assumed greater importance. Mitra cited rural development as a possible contributory factor to the slowing down of urbanization and noted "the new sense of power and destiny that the villager has gained, together with the rise in grain prices and the increasing profitability of agriculture". Mitra, "Internal migration and urbanization ..." (1967), p. 611; and his "Problems of internal migration ..." (1968), p. 6. Brush, on the other hand, cited the restricted opportunities, facilities and amenities which Indian cities have to offer rural migrants. Brush, "Some dimensions of urban population pressure ..." (1970), pp. 300-301.

<sup>484</sup> See, for example, the special issue of *Revista Latinoamericana de Sociologia* (1969) devoted exclusively to the subject of "La marginalidad en América Latina".

<sup>485</sup> United Nations, *Report on the World Social Situation* ... (1957), p. 128. See also Singer, *International Development: Growth and Change* (1964), pp. 61-64; Bairoch, *Révolution industrielle et sous-développement* (1963), pp. 190-191.

<sup>486</sup> See Eisenstadt, *Modernization: Protest and Change* (1966), pp. 86 ff. with special reference to Latin America.

<sup>487</sup> Matos Mar, "Migration ..." (1961), pp. 182, 186-190; Mortara, "Factors affecting rural-urban migration ..." (1967), pp. 511-512; Herrick, *Urban Migration* ... (1965), pp. 35-38; Smith, *Latin American Population Studies* (1960), pp. 59-60. See also International Labour Office, *Why Labour Leaves the Land* ... (1960), pp. 158, 211-212.

<sup>488</sup> United Nations, *Report on the World Social Situation* ... (1957), p. 181.

<sup>489</sup> MacDonald and MacDonald, "Motives and objectives of migration ..." (1968), p. 434; Matos Mar, "Migration ..." (1961), p. 182.

<sup>490</sup> Caldwell observed, for example, that "The bright lights [of the towns] are not the primary cause of Ghanaian rural-urban migration; the primary causes are much more down-to-earth economic facts; but they exert an important supplementary attraction". Caldwell, *African Rural-Urban Migration* ... (1969), p. 210. See also Prothero, "Socio-economic aspects of rural/urban migration in Africa ..." (1965), p. 278.

<sup>491</sup> In Latin America, school enrolment ratios are generally higher than in the African and Asian countries. See, United Nations Educational, Scientific and Cultural Organization, *Statistical Yearbook, 1970* (1971), table 2.5.

<sup>492</sup> United Nations, *Report on the World Social Situation* ... (1957), p. 181.

aware of the contrast".<sup>493</sup> In Latin America, rural-urban migration results in a more stable urban residence, whereas "in Asia and perhaps even more in Africa, many ... villagers ... seek urban employment ... for the express purpose of earning a specific sum of money" after which they return to their rural families.<sup>494</sup> Among the developing countries today, urbanization in Latin America, as compared with Asia and especially Africa, may be said in very general terms to proceed from higher initial levels, relatively lower population pressure on the land and to be characterized by more rapid rates of economic growth.

## 2. GENERAL THEORIES CONCERNING INTERNAL MIGRATION

213. Most scholars who write about migration theories and models recognize the very imperfect state of present-day theoretical and empirical knowledge of the migration phenomenon.<sup>495</sup> There is considerable agreement that the study of migration has been hampered by the grave deficiencies in migration theories which tend to be "time-bound, culture-bound and descriptive bound".<sup>496</sup> To some extent this situation may be attributed to the greater complexity of migration as compared with the other two components of population change, mortality and fertility. Because it involves a change from a place of origin to a place of destination, migration has both a separative and an additive effect and both aspects are relevant to an understanding of why people move. In this sense its complexity is twice that of mortality and fertility which are concerned with the determinants of only one aspect, either the separations (mortality) or the additions (fertility).<sup>497</sup> Furthermore, both births and deaths are clearly identifiable biological phenomena (although influenced by social and other non-biological factors) whereas migration (defined as a "change of residence" across an "administrative boundary") lacks this precision.<sup>498</sup>

214. Owing in part to the predominantly empirical orientation of demographers and in part to the seriousness of data deficiencies, most migration studies have eschewed generalizations and have tended to be factual reports, describing the volume of the different movements revealed by the data and, where possible, the differential characteristics of the migrants. Among those who have attempted to generalize, two more-or-less distinct approaches may be discerned. One of these, mainly situation-oriented in terms of push and pull factors, has taken as its starting-point the differences in characteristics of the places that have experienced net out-migration and of

those with net in-migration in order to arrive at an explanation of why the migratory movements occurred. The other approach has sought to formulate empirical generalizations describing patterns of migration, preferably in the form of mathematical models and valid as universal laws. The objective of this approach has mainly been descriptive, although, as noted below, some scholars have explored its explanatory potentialities.<sup>499</sup> An illustration of the distinction between these two approaches and their utilization is found in Weber's study of nineteenth-century urbanization.<sup>500</sup>

215. Two famous papers by Ravenstein published in 1885 and 1889, both entitled "The laws of migration",<sup>501</sup> are the starting point for the second approach to migration theory involving the formulation of empirical generalizations in regard to patterns of migration.<sup>502</sup> Some of his laws have been challenged or have been discovered to have exceptions.<sup>503</sup> But his observations that migration is preponderantly of short distance, that the volume of migration diminishes as the distance from the centre of absorption increases, and that most long-distance migration proceeds to "the great centres of commerce and industry"<sup>504</sup> gave rise to the fundamental idea underlying the gravity models of Kant and Zipf.<sup>505</sup> According to these, migration is directly proportional to the product of the populations of the places of origin and destination and inversely proportional to the distance between them. On the other hand, Stouffer's well-known model of intervening opportunities denies that there is any necessary relationship between mobility and distance. He formed the hypothesis that the number of persons

<sup>499</sup> Germani, "Migration and acculturation" (1964), pp. 159-160; Bogue, *Principles of Demography* (1969), p. 755; Petersen, *Population* (1961), p. 607; Folger, "Models in migration" (1958), p. 157.

<sup>500</sup> Weber, *The Growth of Cities in the Nineteenth Century ...* (1899; 1963 ed.). The book includes one chapter on the causes of concentration of population which analyses the forces that "act upon men in various ways to produce the necessary shifting of population" (p. 209). A section of the following chapter lays down three laws and discusses another hypothesis on the "nature of the migratory movement" (p. xxii).

<sup>501</sup> Ravenstein, "The laws of migration" (1885 and 1889).

<sup>502</sup> However, the laws Weber presented draw not only upon Ravenstein but also upon the earlier work of Von Mayr who "made the first thorough investigation in the field of internal migration in 1871 ...". Weber, *The Growth of Cities in the Nineteenth Century ...* (1899; 1963 ed.).

<sup>503</sup> For example, it was noted in section B that his law that females predominate among short-distance migrants appears not to be valid in many parts of Africa and Asia. See also Price, "Distance and direction ..." (1948). Weber produces statistics which place in doubt, without entirely disproving, the hypothesis that internal migration proceeds *stapelweise*, i.e., "by stages through village, town, city and metropolis". Weber, *The Growth of Cities in the Nineteenth Century ...* (1899; 1963 ed.).

<sup>504</sup> For a concise statement of Ravenstein's laws based on a selected arrangement of quotations from the 1885 and 1889 papers referred to above, see Lee, "A theory of migration" (1966), p. 48. A further discussion can be found in Macisco and Pryor, "A reappraisal of Ravenstein's 'laws' of migration ..." (1963). Heberle found support for one of Ravenstein's laws in the finding of an inverse correlation between the rate of mobility and size of city in Germany. Heberle, "Migratory mobility ..." (1955), p. 532. See also Heberle and Meyer, *Die Grossstädte ...* (1937).

<sup>505</sup> Pred, *The External Relations of Cities ...* (1962), p. 6; Kant, "Den inre omflyttningen ..." (1946), pp. 83-124; Zipf, "The  $P_1 P_2 / D$  hypothesis ..." (1946).

<sup>493</sup> International Labour Office, *Why Labour Leaves the Land ...* (1960), p. 128.

<sup>494</sup> United Nations, *Report on the World Social Situation ...* (1957), p. 130. See also Caldwell, *African Rural-Urban Migration ...* (1969), particularly chapter 8.

<sup>495</sup> Germani, "Migration and acculturation" (1964), p. 167.

<sup>496</sup> Mangalam and Schwarzweller, "General theory in the study of migration ..." (1968), p. 4.

<sup>497</sup> Bogue, "Discussion ..." (1958), p. 170.

<sup>498</sup> Some of the limitations and ambiguities of this twofold criterion for defining migration are noted in section B above.

migrating a given distance is directly proportional to the number of opportunities at the place of destination and indirectly proportional to the number of intervening opportunities.<sup>508</sup> Various tests have been made by the Zipf and Kant models and the Stouffer model or variants of these models and high correlations between expected and observed migrants have been reported.<sup>507</sup>

216. Laws and models of this kind suffer from the handicap that they tend to describe rather than to explain;<sup>508</sup> nor do they take into account all the diverse circumstances under which migration can occur; also, because they "are incomplete as far as migration factors are concerned, nobody would suggest that they might be used for population projections".<sup>509</sup> Ter Heide has reviewed many of the efforts that have been made to overcome these handicaps so as to make the models more useful. One partial solution has been the use of parameters whose values are dependent on situational factors. Other scholars have qualified the meaning of the factors, distance and population size, in the Zipf-Kant model and then proposed appropriate modifications.<sup>510</sup> Some have experimented with more elaborate mathematical models, involving, for example, stochastic process analyses with Markov chain techniques.<sup>511</sup>

<sup>508</sup> Stouffer, "Intervening opportunities ..." (1940); see also his "Intervening opportunities ..." (1960); Porter, "Approach to migration ..." (1956).

<sup>507</sup> Folger, "Some aspects of migration ..." (1953); Hägerstrand, "Migration and area ..." (1957); Anderson, "Intermetropolitan migration ..." (1955); Agersnap, "Studier over indre Vandringer ..." (1952); Lövgren, "The geographical mobility of labour ..." (1956); Bright and Thomas, "Interstate migration and intervening opportunities" (1941); Isbell, "Internal migration in Sweden ..." (1956); Strodbeck, "Equal opportunity intervals" (1949). For references to other tests see Ter Heide, "Migration models and their significance ..." (1963), pp. 58 and 65; Folger, "Models in migration" (1958), pp. 156-157; and Pred, *The External Relations of Cities* ... (1962), pp. 61 and 63.

<sup>508</sup> According to Pred, *The External Relations of Cities* ... (1962), p. 63, Stouffer's formulation of his intervening opportunities hypothesis was intended to include explanatory variables such as employment possibilities, but this operational definition of opportunities in terms of migrants into an area, in the opinion of many, has circumvented this objective. See Folger, "Models in migration" (1958), p. 158; Lowry, *Migration and Metropolitan Growth* ... (1966), pp. 9-10.

<sup>509</sup> Ter Heide, "Migration models and their significance ..." (1963), p. 71.

<sup>510</sup> Migration may be influenced, for example, not only by sheer geographical distance but also by technical distance in terms of communication and transportation facilities and by social distance in terms of cultural, linguistic and religious differences between places of origin and destination. Ter Heide reports that one aspect of technical distance has been studied in Denmark by Agersnap and that Somermeijer included a social distance factor in a migration model applied to the Netherlands. Others such as Miller, Dodd, Stewart, Isard and Somermeijer have proposed that weights be attached to the population figures in the formula on the basis of relevant differences in their characteristics. Ter Heide, "Migration models and their significance ..." (1963).

<sup>511</sup> Muhsam, "Toward a formal theory of internal migration" (1963); Myers, McGinnis and Masnick, "The duration of residence approach ..." (1967), pp. 121-126; Morrison, "Duration of residence and prospective migration ..." (1967), pp. 553-561. Rogers, *Matrix Analysis of Interregional Population Growth* ... (1968); Tarver and Gurley, "A stochastic analysis of geographic mobility ..." (1965); Kamiya, "Korekara no jinko bumpu ..." (1963); Shimizu, "Waga kuni ni okeru jinko ..." (1964).

217. Somermeijer made a major improvement in the Zipf-Kant model by introducing explanatory "attractiveness factors", each of them with different values in the place of origin and in the place of destination.<sup>512</sup> This innovation enables the model to describe both net and gross migration instead of only the gross migration between two places; in principle (providing appropriate weights can be assigned) it also permits the incorporation of all the explanatory push-pull factors supplied by the situation-oriented approach; it assumes that each factor influences a different class of migrant and allows for different subjective values for different persons within the class of migrants influenced by a given factor.<sup>513</sup> Lowry, acknowledging his indebtedness to Somermeijer, applied a model with nine independent variables to the analysis of internal migration in the United States.<sup>514</sup> Numerous studies conducted in Japan have investigated the importance of disparities in income and employment opportunities between the more urban industrial areas and the more rural agricultural areas as factors explaining internal migration.<sup>515</sup>

218. In the situation-oriented approach to migration theory, explanation has been the chief objective and the push-pull hypothesis has dominated the mode of thinking.<sup>516</sup> In this type of analysis, migration is considered to be "the outcome of the interplay and balance of expulsive forces ... and of attractive forces" in the places of origin and destination.<sup>517</sup> The push-pull hypothesis has proved to be a useful device for listing all the factors affecting a given migratory movement,<sup>518</sup> and has produced lucid and convincing expositions of the underlying factors in

<sup>512</sup> Somermeijer, "Een analyse van de binnenlandse migratie ..." (1961).

<sup>513</sup> Ter Heide, "Migration models and their significance ..." (1963), pp. 57-64, 67-69. Others working with models have also commented on the need to take into account the difference between the objective factors affecting migration and the potential migrants' perception of these factors. Folger, "Models in migration" (1958), p. 162; Muhsam, "Discussion ..." (1958), pp. 169-170.

<sup>514</sup> Lowry, "Migration and metropolitan growth ..." (1966), p. 11 ff. Also of interest is the model tested by Sahota with interstate migration data from the 1950 Brazilian census. See his "An economic analysis ..." (1969), pp. 73-88. See also Greenwood, "An analysis of the determinants of geographic labor mobility ..." (1969); Sjaastad, "The relationship between migration and income ..." (1960).

<sup>515</sup> See for example, Umemura, *Chingin, Koyo, Nogyo* (1961), pp. 203-205; Nishikawa, *Chiiki-kan Rodo Ido* ... (1966), pp. 227-239; Kanekiyo, *Hito no Ugoki* ... (1970), pp. 110-112; Okazaki, *Nihon no Rodoryoku Mondai* (1966), pp. 132-133; Tachi, "Kokunai jinko ido no kino" (1967), and his "Regional income disparity and internal migration ..." (1964), pp. 186-204; Tachi and Misawa, "Nihon ni okeru kokunai ..." (1969), pp. 1-19; Suzuki, "Rodoryoku no chiiki-kan ido" (1968); Kono and Shio, *Inter-Prefectural Migration in Japan* ... (1965). Some of these studies took into account the factor of distance, as well as demographic and social factors which were considered to function as intervening variables which might modify the direct relationship between economic factors and migration.

<sup>516</sup> Mangalam and Schwarzweller, "General theory in the study of migration ..." (1968), p. 8.

<sup>517</sup> Germani, "Migration and acculturation" (1964), p. 159.

<sup>518</sup> For examples of such inventories, see Mortara, "Factors affecting rural-urban migration ..." (1967); Smith, *Latin American Population Studies* (1960), pp. 59-60; and Bogue, "Internal migration" (1959), pp. 499-501.

migration.<sup>519</sup> The approach in and by itself, however, does not lead to any theory and some students of migration have questioned the adequacy of its basic concepts. The force of accumulated push and pull factors can be so overwhelming that it neglects to make clear "why . . . some migrate and some not".<sup>520</sup> The use of Lee's conceptual framework<sup>521</sup> which incorporates push and pull factors at both the origin and destination would overcome this limitation. Another difficulty with push-pull analysis emerges when an attempt is made to characterize the combined effect of all the factors as predominantly either push or pull.<sup>522</sup> Some scholars have avoided this kind of difficulty by observing that many push and pull factors can be mated into pairs, each pair representing two different values of one single variable.<sup>523</sup> Following this line of reasoning some have concluded that the push-pull dimension is a subjective characteristic of migration. Whether the individual migrant thinks of himself as being pushed by the poorer job, health, educational, and other conditions in his rural habitat or is attracted by the better urban conditions depends in part on his evaluation, and may well be different before and after the fact of migration.<sup>524</sup> While personal reasons and individual motivations are important during the pioneer phases of a migratory movement, they are of little interest during the mass or social movement phase which is largely sustained by imitation and inertia.<sup>525</sup> Nevertheless, under circumstances of rapid change taking place only at the origin or only at the destination, a movement might more clearly and legitimately be distinguished as push or pull.

219. The greatest challenge to migration theorists is the organization of all hypothetically relevant factors into one coherent theoretical framework that will specify their interaction with each other in empirically testable form and thereby serve as a guide to future research.

<sup>519</sup> See, for example, Weber, *The Growth of Cities in the Nineteenth Century* . . . (1899; 1963 ed.), chap. 3; Saville, *Rural Depopulation* . . . (1957), chap. 1; and International Labour Office, *Why Labour Leaves the Land* . . . (1960).

<sup>520</sup> Petersen, *Population* (1961), p. 607.

<sup>521</sup> Lee, "A theory of migration" (1966), pp. 49-51. See chapter VII, section B for a further discussion of this framework.

<sup>522</sup> For example, a number of studies have concluded that rural-urban migration in the less developed countries today is activated primarily by push, whereas in the more advanced countries the pull factors have been stronger. Germani, "Migration and acculturation" (1964), p. 160; McGee, *The Southeast Asian City* . . . (1967), pp. 84-85; Sjöberg, "Rural-urban balance . . ." (1966), p. 243.

<sup>523</sup> Thus Herrick unifies the push and pull hypotheses of lower rural and higher urban income into "one in which urban migration is a function of expected rural-urban income differences." Herrick, *Urban Migration* . . . (1965), p. 14. Similarly, Kuznets and Thomas speak of differential economic opportunities. See their "Internal migration and economic growth" (1958). Todaro devised a model for analysing the determinants of urban labour supply which takes into account differential expected real earnings in urban and rural employment, after allowance is made for the probability of finding an urban job. See his "A model of labor migration . . ." (1969); see also Harris and Todaro, "Migration, unemployment and development . . ." (1970).

<sup>524</sup> Sjöberg, "Rural-urban balance . . ." (1966), p. 243.

<sup>525</sup> Mortara, "Factors affecting rural-urban migration . . ." (1967), p. 512; Petersen, *Population* (1961), p. 608. See section B for a further discussion of the pioneer and mass phases of migratory movements.

Generally speaking, the more elaborate frameworks remain on the drawing-board because of data deficiencies and other difficulties in their application; analytical systems which have been designed for use with a specific body of data have necessarily had to sacrifice rigour and elegance of formulation.<sup>526</sup> Because of the existence of many diverse types of migration, some scholars have abandoned the search for universally valid generalizations about migration in preference for the construction of migration typologies,<sup>527</sup> as a necessary preliminary step in the development of migration theory.

220. Among the theoretical frameworks which have been formulated for migration analysis, those of the economists Schultz and Sjaastad consider internal migration in terms of costs and returns on investments in human capital. The costs of the investment, such as moving costs, earnings foregone while searching and training for a new job and psychic costs such as homesickness, must be compared with the returns, such as expected better earnings etc.<sup>528</sup> Petersen, a sociologist, has urged that an attempt be made "to distinguish among underlying causes, facilitative environment, precipitants and motives".<sup>529</sup> Germani devised a sociological framework that identifies three levels of analysis: an objective level and two subjective levels, the normative and psychosocial levels.<sup>530</sup> His framework is principally programmatic and he uses it to indicate the kind of data a researcher should look for in a rural-urban migration study. In view of the complexity of the conceptualization of the objective and subjective components of migration motivation, and the design of surveys investigating them in depth, it is understandable that most migration studies and surveys have in the past pursued more limited aims.

<sup>526</sup> Weber's analysis published in 1899 still remains highly pertinent. See his *The Growth of Cities in the Nineteenth Century* . . . (1899; 1963 ed.), pp. 157, 209-222. For Weber the principal cause of migration is the economic (or structural) forces comprised under the term "economic organization of society" to which population distribution adjusts following the line of least resistance. After tracing the structural evolution of rural and urban centres, he introduces a group of "secondary or individual causes" classified into economic, political (with five sub-categories), and social (with six sub-categories).

<sup>527</sup> Petersen, *Population* (1961), p. 607. Petersen's typology distinguishes "innovating" from "conservative" migration on one dimension, and five broad classes of migrants' level of aspiration on the other dimension. Heberle's typology also uses two dimensions: the social relationships of the migrants and differences in socio-cultural systems between areas of origin and of destination. Heberle, "Types of migration" (1956), p. 1. Another typology that is basic to any discussion of factors affecting migration is that which distinguishes, on the one hand, between those persons who make the decision to migrate and, on the other hand, those persons whose migration is merely derivative from a decision made by the head of the family. Shryock designated these two kinds of migration respectively as "primary migration" and "secondary migration". Shryock, *Population Mobility* . . . (1964), pp. 403-409.

<sup>528</sup> For a summary of much of their work, see Schultz, "Reflections on investment in man" (1962) and Sjaastad, "The costs and returns of human migration" (1962). The brief description presented here is taken in part from Herrick, *Urban Migration* . . . (1965), pp. 18-20, and in part from Sahota, "An economic analysis . . ." (1969), pp. 74-75. This kind of model is clearly appropriate to countries with market economies, such as the United States, and not to socialist economies, such as the Soviet Union.

<sup>529</sup> Petersen, *Population* (1961), pp. 607-608.

<sup>530</sup> Germani, "Migration and acculturation" (1964), pp. 160-163.

### 3. THE ECONOMIC FUNCTIONS OF CITIES

221. The most commonly used approach to the study of urban economic functions is the economic base concept.<sup>531</sup> While there remains a considerable controversy over both the actual meaning of the "economic base" and its analytical validity, it remains one of the fundamental tools for urban economic analysis.<sup>532</sup> As it is generally used, this concept relies upon the distinction between those activities which are essential to urban growth and those which exist primarily to support these activities. Accordingly, the "basic" or "city-forming" activities involve those functions that relate to the processing or trading of goods or the provision of services or capital for residents or establishments located outside the urban area. "Non-basic", "service", "city-serving", or "city-filling" activities comprise the complement to the economic base.<sup>533</sup> Consequently, basic activities, by serving as the urban equivalent to the national "export" sector, are considered to be the key to the levels and growth of urban employment, income and population.<sup>534</sup>

222. Methodological difficulties have hampered the effectiveness of the economic base approach,<sup>535</sup> since most activities are neither purely basic nor totally non-basic in their function. For example, the manufacturer of a product may be producing some of his output for local consumption and some of it for export. Since data

<sup>531</sup> The nature of the theory of economic base was first explicitly stated in Weimer and Hoyt, *Principles of Urban Real Estate* (1939). For a comprehensive discussion of the development, uses, and shortcomings of economic base theory, see Pfouts, ed., *The Techniques of Urban Economic Analysis* (1960); especially the articles by Andrews, "Mechanics of the urban economic base ..." (1960); Alexander, "The basic-nonbasic concept of urban economic functions" (1960); Blumenfeld, "The economic base of the metropolis" (1960); and Tiebout, "The urban economic base reconsidered" (1960). See also Mattila and Thompson, "The measurement of the economic base ..." (1961); Stewart, "Economic base dynamics" (1959); Ullman and Dacey, "The minimum requirements approach ..." (1960); Tiebout, *The Community Economic Base Study* (1962); Hoover, *An Introduction to Regional Economics* (1971), pp. 221-224; Richardson, *Regional Economics* ... (1969), pp. 165-170.

<sup>532</sup> For a comprehensive discussion of the problems of terminology, see Andrews, "Mechanics of the urban economic base ..." (1960), pp. 39-50. Pfouts, ed., *The Techniques of Urban Economic Analysis* (1960), pp. 213-358, delineates the theoretical objections to the economic base theory. See also Isard, *Methods of Regional Analysis* ... (1960), pp. 199-205.

<sup>533</sup> An early statement of this distinction was made by Nussbaum, *A History of the Economic Institutions of Modern Europe* ... (1933), p. 36: "The principal elements of the town were those who are able by power or wealth to command a means of subsistence from elsewhere, a king who can tax, a landlord to whom dues are paid, a merchant who makes profits outside the town, a student who is supported by his parents. These are 'town builders'. After them come what we call the 'town fillers', those who serve the needs of the 'town builders'; the shoemaker who makes the king's shoes, the jeweller who depends on the purchases of the merchant's wife, the landlady from whom the student rents his room."

<sup>534</sup> Ferguson, "Statics, dynamics, and the economic base" (1960), notes that in its static form the economic base hypothesis "states that residentiary employment, income, and population can be explained and predicted by reference to employment in basic activities", and in its dynamic form "the rate of change in residentiary employment, income, or population is functionally dependent on the level of employment in basic activities".

<sup>535</sup> For a discussion of the technical and conceptual difficulties of economic base studies, see Isard, *Methods of Regional Analysis* ... (1960), pp. 194-205.

are rarely available in such detail, an accurate identification of the economic base is not easily achieved. In Andrews's view, one of the reasons that the analytical tools for economic base identification have as yet been insufficiently refined is that most of the work in this area has been undertaken as part of a larger project, and measures of expediency have frequently been adopted in view of the variety of problems to be dealt with.<sup>536</sup>

223. The gauge most commonly used to measure the economic base is the number of people employed, tabulated by industry, since, in most countries, employment data are relatively easy to obtain. Other less frequently used alternatives include total payrolls, income payments and "value added" by activity.<sup>537</sup> All of these approaches suffer from conceptual and technical difficulties, and some authors have concluded that the best theoretical alternatives to employment data are empirically impracticable.<sup>538</sup> Various indices utilizing employment data have been constructed to identify the urban economic base, the most common being the ratio of an industry's share in local employment to its share of national employment, or the ratio of a locality's share of national employment in a particular industry to the locality's share of total national employment.<sup>539</sup>

224. Other techniques, as well as economic base studies, have been used to construct classification schemes of urban functions. Frequently, the principal functions of cities have been identified on the basis of industrial or occupational employment data. Rather complex indices have sometimes been adopted which take account of the fact that few cities are characterized by any single activity and many carry on several functions which may constitute distinguishing features. Many of the classification schemes consider social and demographic, as well as economic characteristics.<sup>540</sup>

225. Harris and Ullman have suggested the following classification of urban functions: (1) central-place cities, which perform centralized services, such as retail trade and political administration, for the adjacent areas,

<sup>536</sup> Andrews, "Mechanics of the urban economic base ..." (1960), pp. 95-96.

<sup>537</sup> Isard, *Methods of Regional Analysis* ... (1960), pp. 194-195. For a discussion of the benefits of using "value added", see Leven, "Measuring the economic base" (1956).

<sup>538</sup> Mattila and Thompson, "The measurement of the economic base ..." (1961), p. 332.

<sup>539</sup> For a discussion of these and other indices, see *ibid.*, p. 333 ff.

<sup>540</sup> Arousseau, in an early classification, identified six major functional types of cities. See his "The distribution of population ..." (1921). The following are among the many other classifications which have been developed: Ogburn, *Social Characteristics of Cities* (1937); Harris, "A functional classification of cities ..." (1943); Kneeder, "Functional types of cities" (1945); Jones, "Economic classification of cities and metropolitan areas" (1953); Bergel, *Urban Sociology* (1955), pp. 150-152; Duncan and Reiss, *Social Characteristics of Urban and Rural Communities* ... (1956); Nelson, "A service classification of American cities" (1955); and Pownall, "The functions of New Zealand towns" (1961). A number of studies have used factor analysis in the development of classifications of cities involving a large number of variables. See Price, "Factor analysis in the study of metropolitan centers" (1942); Moser and Scott, *British Towns* (1961); and Hadden and Borgatta, *American Cities* ... (1965).

variously called by geographers and economists as service areas, hinterlands, or urban fields etc.; (2) transport cities, which owe their economic base primarily to their location with respect to the transport network, including railway centres and ports; and (3) specialized function cities, performing one service such as mining, manufacturing, or recreation for large areas.<sup>541</sup>

#### 4. THE LOCATION OF ECONOMIC ACTIVITIES

226. It has been noted that "the locations and functions of cities are so closely related that a full explanation of one requires an explanation of the other".<sup>542</sup> Since the distribution of population is highly dependent upon the distribution of economic activities,<sup>543</sup> any meaningful discussion of the process of urbanization must consider the principles governing their location. This has been the objective of both the classical and modern location theorists, who have dealt with such problems as the locational equilibrium of each firm or the possibility of a general equilibrium of all firm locations. The discussion of the principles of location generally follows a theoretical approach emphasizing the efficiency of each economic unit of activity as the basis for analysis.

227. Of those activities which account for the growth of major cities, industry is generally the most important. Alfred Weber, in his classic work on industrial location, notes that "the location of industries forms the 'substance' (I do not say the cause) of the large agglomerations of people today".<sup>544</sup> His analysis, along with the later works of Lösch, Hoover and Isard, has provided the basis for most explorations into the factors influencing the location of industry.<sup>545</sup>

228. The influence on the location of industries of space relationships such as the distance from sources of raw materials and markets for finished products, and the availability of means of transport, is discussed in section A above. It was also noted that there is a tendency for each type of economic activity to be linked to other types so that a concentration develops in a particular locality. Once the infrastructure required by industries is provided—such as power supplies, communications networks, transportation facilities, and administrative services—there exist factors which encourage the location of additional industry in the same area. These might be broadly classified as "external economies", and include all of those requirements of industry which are not characteristic of an individual firm's production function but which have significant importance in the reduction of costs.<sup>546</sup> By locating near to already existing trans-

portation or communications facilities, for example, a firm can save itself the cost of providing them at its own expense. The prior existence of an industrial base creates an impetus for further industrialization, and, consequently, urban concentration.<sup>547</sup>

229. Concentration is also characterized by several external diseconomies. These do not normally become apparent until the city has grown very large and they include such factors as excessive transportation costs due to congestion, high land costs because of demand for centrally located property, higher production costs resulting from expensive treatment of polluted air or water etc. Factories located away from other activities, for example, are normally able to disregard such costs, but when they are situated in an urbanized area they usually cannot do so. The air and water effluence of industrial processes creates many costs which are imposed upon society as a whole in the form of pollution and possibly poor health. Individual firms do not ordinarily enter such costs into their accounts. If they did, the advantages of urban locations would eventually be visibly lessened, and many activities would tend to be relocated in other areas.<sup>548</sup>

230. Optimally, urban growth should begin to diminish when the marginal costs to the community begin to outweigh the marginal benefits.<sup>549</sup> The full range of social costs and benefits are not capable of being quantified, however, and this prevents the implementation of such a policy. Nor can the ultimate effect of time and technological change be fully comprehended. In most market economies individual firms are not required to internalize external social costs and individual firms tend to oppose legislation that would oblige them to do so.<sup>550</sup> Furthermore, some authors believe that *entrepreneurs* tend to overemphasize the advantages of urban locations and consequently often place themselves in big cities though, on strictly economic grounds, this is not always rational.<sup>551</sup> Of course, the presence of cultural amenities which can be enjoyed in major cities may be among the non-economic incentives for such location. As noted

<sup>547</sup> It has been observed that "the economic significance of cities lies in the external economies that they provide". See Tsuru, "The economic significance of cities" (1963). Lampard is more explicit: "It is precisely because urban sites offer an array of 'scale'-type economies almost regardless of actual plant-size that concentration endures. For example, better transfer facilities, broader and more flexible labor markets, numerous auxiliary business services like banking, insurance, brokerage, utilities, or fire and police protection. To these may be added increasing returns to larger operations, various economies of integration (used here in the sense of control), bulk purchase and handling, complementary factor requirements, greater density and frequency of customers: in short, most of the advantages of scale-economy and greater specialization." See his "The history of cities in the economically advanced areas" (1955), pp. 95-96.

<sup>548</sup> Such forces of deglomeration were recognized by Alfred Weber. See his *Theory of the Location of Industries* (1929), especially p. 132.

<sup>549</sup> See United Nations, *Urbanization: Development Policies and Planning* ... (1968), p. 75.

<sup>550</sup> Thus, there is great resistance to efforts to promote programmes of pollution control in which the producer bears the costs.

<sup>551</sup> Hirschman, *The Strategy of Economic Development* (1958), p. 185.

<sup>541</sup> Harris and Ullman, "The nature of cities" (1957).

<sup>542</sup> Duncan *et al.*, *Metropolis and Region* (1960), p. 31.

<sup>543</sup> See the discussion in section A above.

<sup>544</sup> Weber, *Theory of the Location of Industries* (1929), p. 6.

<sup>545</sup> Lösch, *The Economics of Location* (1954); Hoover, *The Location of Economic Activity* (1948); and Isard, *Location and Space Economy* ... (1956).

<sup>546</sup> Isard, in *Methods of Regional Analysis* ... (1960), pp. 404-405, calls such economies of location, "spatial-juxtaposition economies" and divides them into "localization economies", which are obtained when plants of like character (generally within a given industry) congregate at one site, and "urbanization economies", which are defined as economies which emerge when unlike plants congregate around one site.

earlier, some writers have argued that under conditions of socialist central planning the distribution of industrial locations can become economically more rational.<sup>552</sup>

## 5. CENTRAL PLACE THEORY

231. Many non-industrial urban activities must be centrally located in relation to the market areas they serve. For the most part, these are tertiary activities involving little use of raw material but mainly the distribution of goods and services: wholesale and retail trade and administrative, financial and personal services. These activities are found in varying degrees in cities, towns and villages of all sizes and their distribution has been observed to correspond closely to the number, size and spacing of populated centres. These functions, therefore, are called "central-place" activities, or functions, and the places in which they are concentrated are called central places.

232. The development of the concept of central places is generally attributed to Christaller.<sup>553</sup> Lösch later included it in his more comprehensive work on the location of economic activities.<sup>554</sup> In Christaller's view, "the geography of settlements is a part of economic geography" and therefore must draw upon economic theory in order to explain the character of towns.<sup>555</sup> His underlying assumption was that the basic function of a city, town, or village is that of a regional centre to provide services and distribute goods to that region—in other words, to serve as a central place. By concentrating upon the factors influencing the location of economic activities on a uniform plain, Christaller and Lösch provide an explanation of why, even in the absence of any significant geographic differentiation, there should arise a hierarchy of urban places. Significantly, Christaller's scheme has been widely regarded as a "theoretical framework for the study of the distribution of settlements".<sup>556</sup>

233. The analysis is based upon the notion that those activities which serve a surrounding population vary greatly in the minimum purchasing power needed for their support.<sup>557</sup> This minimum sales volume is a "condition of entry", or threshold, for the existence of any business establishment.<sup>558</sup> Corresponding to this threshold is some minimum number of consuming units, depending upon the distribution of population within the

region, its characteristic income distribution, its consumption patterns, and the cost and price of the central good or service. The smallest ring circumscribing the central place that contains the needed number of consuming units is a commodity's "real range". Also associated with the good or service is an "ideal range", defined by its economic distance which Christaller describes as "the farthest distance the dispersed population is willing to go in order to buy a good offered at a place—the central place."<sup>559</sup> The number of central places that exist reflects the difference between the ideal and the real ranges. So long as the real range is smaller than the ideal range, the market is capable of supporting the same activity at other places within the region, thus tending to eliminate all surplus profit.<sup>560</sup> At equilibrium, when the ideal and real ranges have been made equal, a network of hexagonal market areas surrounding the central places tends to result.<sup>561</sup>

234. Such a network can be shown theoretically to exist for every central place activity. Since each of them is characterized by a different threshold and range, the hexagonal market areas for each are of different size. If each of these activities is considered in relation to the same extent of land, then some of the points will serve as central places for many of the activities and many of them will only be central places for the more ubiquitous of them, possessing relatively small market areas. The functions of the former group of places—"central places of a higher order"—extend over larger regions encompassing the "central places of a lower and of the lowest order."<sup>562</sup> The regions associated with the central places are similarly defined as complementary regions of a higher order and complementary regions of a lower order.<sup>563</sup>

235. One of the principal advantages of central place theory, in contrast to economic base or industrial location studies, is that it treats the city or region in relation to a hierarchy of other related cities or regions, whereas most other studies are mainly concerned with each individual city or region under consideration. Philbrick has hypothesized a sevenfold hierarchy of nested functions corresponding to seven nested orders of areal units of organization.<sup>564</sup> Within the hinterland of each central place of a given order are a finite number of establishments of the

<sup>552</sup> George, *Introduction à l'étude ...* (1951), pp. 127-143; and Balzak, Vasyutin and Feigin, eds., *Economic Geography ...* (1949), pp. 109-110, 130-132, 167-196. See also section A.

<sup>553</sup> Christaller, *Central Places in Southern Germany* (1966). This work was originally published in German in 1933.

<sup>554</sup> Lösch, *The Economics of Location* (1954).

<sup>555</sup> Christaller, *Central Places in Southern Germany* (1966), p. 31. Christaller expressed the hope that his contribution might be regarded as "the theory of location of the urban trades and institutions, to correspond with von Thünen's theory of location of agricultural production and Alfred Weber's theory of location of industries ..." *Ibid.*, p. 7. See von Thünen, *Der isolierte Staat ...* (1826; 1875 ed.), regarded as one of the early important works on location theory. For a concise summary of the theory, see Chisholm, *Rural Settlement and Land Use* (1967), pp. 21-35. See also Weber, *Theory of the Location of Industries* (1929).

<sup>556</sup> Ullman, "A theory of location for cities" (1959), p. 203.

<sup>557</sup> Berry and Garrison, "A note on central place theory ..." (1958).

<sup>558</sup> Mayer, "A survey of urban geography" (1965), p. 90.

<sup>559</sup> Christaller, *Central Places in Southern Germany* (1966), p. 22. The economic distance itself is determined—with respect to goods rather than services—by (1) freight, insurance and storage costs, and (2) time and loss of weight or space in transit; with respect to passenger travel, the economic distance is determined by (1) the cost of transportation, (2) the time required, and (3) the discomfort of travel.

<sup>560</sup> Lösch, *The Economics of Location* (1954), p. 109. The argument is similar to the results of product differentiation as discussed by Chamberlin, *The Theory of Monopolistic Competition* (1933) and Robinson, *The Economics of Imperfect Competition* (1933).

<sup>561</sup> Christaller, *Central Places in Southern Germany* (1966); Lösch, *The Economics of Location* (1954), pp. 109-123.

<sup>562</sup> Christaller, *Central Places in Southern Germany* (1966), p. 17.

<sup>563</sup> *Ibid.*, p. 21.

<sup>564</sup> Philbrick, "Areal functional organization in regional geography" (1957); and Philbrick, "Principles of areal functional organization in regional human geography" (1957).

next lower order. This study emphasizes that "associated with a statistically regular hierarchy of cities must be a statistically regular hierarchy of commodity flows as characterized by both average length and volume of flow. Therefore it is to be expected that the structure of the internal economy of cities will differ according to order in hierarchy. To each order of city will correspond a different set of activities producing for export." This implies that the growth of a hierarchy of regions implies changing economic base and basic-service ratios for these regions.<sup>565</sup>

236. As is the case with most theory, however, the critical assumptions upon which central place theory depends are never obtained in reality. Differences in the natural factor endowments exist throughout geographic space: resources vary in type, quality, and quantity; variation in the accessibility of different locations results from topographical features such as rivers, lakes, mountains, deserts, swamps; the population is not initially uniformly distributed over the land etc. Consequently, it is unlikely that the hypothesized distribution of central places, and hence urban locations, ever exists in reality.

237. Despite the possible impact of such distorting factors, however, the conceptual framework provided by central place theory appears to be generally valid and improved methodology can be expected in this area in the future.<sup>566</sup> While they do not constitute proof of its validity, a number of studies have indicated that the central place hierarchy does seem to exist in cases where the strict assumptions underlying the theoretical framework are approximated.<sup>567</sup> This is most nearly the case in agricultural regions with little industrial development.

## 6. "LAWS" OF CITY-SIZE DISTRIBUTION

238. The spatial interrelationships of economic activities, especially as suggested by Christaller and Lösch, define an intricate network of urban places distributed over space. This, in turn, implies a hierarchy consisting of many small villages and towns fairly uniformly dispersed

<sup>565</sup> Isard, *Methods of Regional Analysis* ... (1960), p. 227. Also see Friedmann, "Locational aspects of economic development" (1956); Lampard, "The history of cities in the economically advanced areas" (1955); Stolper, "Spatial order and the economic growth of cities ..." (1955).

<sup>566</sup> One technique which is being investigated is the adoption of the concept of entropy to measure the order of the hierarchy. See Medvedkov, "The concept of entropy in settlement pattern analysis" (1967) and Fano, "Organization, city size distributions and central places" (1968). Another approach is through topological analysis. See Medvedkov, "An application of topology in central place analysis" (1967).

<sup>567</sup> Among the studies that have considered this problem are: Smailes, "The urban hierarchy in England and Wales" (1944); Bracey, "Towns as rural service centers ..." (1953); Brush, "The hierarchy of central places ..." (1963); Brush and Bracey, "Rural service centers in ..." (1955); Carruthers, "A classification of service centers ..." (1957); Berry and Garrison, "A note on central place theory ..." (1958); Berry and Garrison, "The functional bases of the central place hierarchy" (1958). Central place theory has also been discussed in relation to the situations in Nigeria, China, and the USSR. See Mobogunje, *Urbanization in Nigeria* (1968); Skinner, "Marketing and social structure in rural China" (1964); and Kovalev, "Razvitiye seti gorodskikh poselenii ..." (1954).

over the landscape and of fewer urban places in each successively larger size class. This hierarchy has often been referred to as a "system of cities", implying that it is a reflection of their functional and spatial interdependence.<sup>568</sup> Its apparent regularity has led to numerous attempts to describe and quantify it and to explore the reasons for its occurrence.

239. The most commonly discussed empirical rule involves a class of skewed distributions suggested by Pareto's inverse exponential law of income distribution when applied to the populations of cities. This might be expressed as  $RS^a = 10^4$ , where  $S$  is the number of inhabitants in a given city,  $R$  is the number of towns with  $S$  or more inhabitants (the rank of the town), and  $A$  and  $a$  are parameters.<sup>569</sup> An important sub-case of this relationship is known as the rank-size rule. According to Zipf, the size of a city varies inversely with its size-rank in an order running from the largest to the smallest in the group of cities under consideration. This rule is further specified to the effect that a city's rank in a national "system" of cities multiplied by its size tends to be a constant, which is equal to the size of the largest city.<sup>570</sup> The number of cities, together with the fraction of the population living in the largest cities, depends on the strength of "unification".<sup>571</sup> His analysis includes an attempt to show how changes in the conditions surrounding economic activities make for the ascendancy of either the "force of unification" or the "force of diversification" and consequently for a redistribution of the population among the communities comprising a nation. This redistribution tends to proceed in accordance with the rank-size rule and its corollaries.<sup>572</sup>

240. Lotka, who was one of the earliest scholars to observe the statistical regularity that existed in the distribution of population among cities of different sizes, noted that "it may be left an open question how much

<sup>568</sup> See Hoover, "The concept of a system of cities ..." (1955); and Berry, "Cities as systems within systems of cities" (1964).

<sup>569</sup> Singer, "The 'courbe des populations' ..." (1936), p. 254. Perhaps the first attempt to formulate in terms of a "law" the distribution of population among cities of varying size was that of Auerbach, "Das Gesetz der Bevölkerungskonzentration" (1913).

<sup>570</sup> Stewart states Zipf's rank-size rule as follows:  $R^n S_R = M$ . Here  $M$  and  $n$  are constants,  $R$  is the rank of the city in question, and  $S$  stands for the number of people who live in the  $R$ th city in the group. The constant  $M$  is equal in size to the population of the largest city, while the exponent  $n$  equals unity except in those countries which are less advanced or unevenly developed and which have an exponent less than unity. Stewart, "Empirical mathematical rules concerning ..." (1947), pp. 462-468. According to Stewart: "the rank-size rule represents an equilibrium among competing cities", *ibid.*, p. 469.

<sup>571</sup> Let  $P$  represent the population of the largest community in a group of  $n$  communities; and  $P.S_n$ , the total population living in the  $n$  communities. Then

$$P.S_n = \frac{P}{1^p} + \frac{P}{2^p} + \frac{P}{3^p} + \dots + \frac{P}{n^p}$$

"The exponent,  $p$ , will increase and  $n$  will decrease, under the increasing relative magnitude of the force of unification." Zipf, *Human Behavior* ... (1949), p. 366.

<sup>572</sup> Zipf, *Human Behavior* ... (1949), chaps. 9 and 10; and his *National Unity and Disunity* (1941), chap. 3. On applications to a given "system of cities" see Madden, "On some indications of stability in the growth of cities ..." (1956).

TABLE VI.14. SIZE-OF-PLACE STRUCTURE FOR THE WORLD, 1950 AND 1960,  
FOR PLACES WITH 125,000 OR MORE INHABITANTS

Size-class (thousands)	Population in cities (thousands)		Number of cities	
	1950	1960	1950	1960
Total .....	383,339	566,909	757	1,071
8,000 and over .....	22,724	34,751	2	3
4,000-8,000 .....	47,004	76,136	9	13
2,000-4,000 .....	38,937	70,523	15	27
1,000-2,000 .....	72,970	100,798	53	71
500-1,000 .....	73,023	98,107	108	138
250-500 .....	63,180	91,727	189	268

significance is to be attached to this empirical formula".<sup>573</sup> Simon and Rashevsky have both expressed interest in the mathematics of the relationships, but have offered little in the way of explanations for their existence.<sup>574</sup> Berry, who made numerous tests of the rank-size rule, concluded that the existence of log-normality, a more generalized form of the rank-size relationship, is principally due to the interaction of many contributory factors to the growth of the urban system rather than to a few dominant forces.<sup>575</sup>

241. Both Lösch and Hoover have observed that the size distribution of cities in a central place scheme should closely follow a Pareto distribution.<sup>576</sup> If a Pareto distribution of urban places exists in actuality, it would seem that it should perhaps be attributed to the rational location of economic activities. In such a distribution, if size-of-place categories are selected so that the upper and lower limits of each size group represent a doubling (or some other constant multiple) of the next lower size class (e.g., 125-250, 250-500, 500-1,000 etc.), then the amount of population in each size group will tend to be equal to the amount of population in the other size groups.<sup>577</sup> Correspondingly, the number of cities in each progressively larger size category tends to be roughly one-half the number in the next lower size category,<sup>578</sup> or at least it can be said that the number of cities in each size category varies inversely with the size of city.<sup>579</sup> In literature

concerned with the distribution of the population by localities of diverse size, this is generally referred to as the "rank-size rule".

242. In a strictly empirical study, Davis found that the 1950 and 1960 size-of-place structure among cities of the world with 125,000 or more inhabitants could be described, with some exceptions, as roughly consistent with the characteristics described above. Some of his statistics are summarized in table VI.14.<sup>580</sup> It must be emphasized, however, that these observations are based only on the combined world-wide data. The patterns for individual countries and regions vary considerably, especially in small countries.

243. Beckmann has concluded that "the empirical rank-size rule ... is compatible with the ideas on hierarchies of market areas and their central cities as developed by Lösch and other location theorists".<sup>581</sup> It might be noted, however, that although a Pareto distribution might be compatible with the central place scheme, an empirical fit of the Pareto curve hardly validates central place theory. While such curves may provide an excellent fit to the size distribution of the largest cities, the largest cities of a country rarely have locational and functional characteristics that can be accounted for by a strict central place rationale.<sup>582</sup>

244. If the rank-size rule or some variation of it is the result of the rational location of economic activity, this concept might be usefully applied in planning for industrial and economic development. Berry has warned, how-

<sup>573</sup> Lotka, *Elements of Physical Biology* (1925), p. 307.

<sup>574</sup> Simon, *Models of Man* ... (1957); Rashevsky, *Mathematical Biology of Social Behavior* (1959).

<sup>575</sup> Berry, "City size distributions and economic development" (1961). See also his "Research frontiers in urban geography" (1965); and Mayer, "A survey of urban geography" (1965).

<sup>576</sup> Lösch, *The Economics of Location* (1954), pp. 433-436; Hoover, "The concept of a system of cities" (1954).

<sup>577</sup> This is true in the most widely used models which generally make use of the simple assumption of a unity gradient. Other gradients have also been taken into consideration by which numbers of population in successive size groups tend to increase or diminish at a constant rate.

<sup>578</sup> If the class size limits are not in a ratio of one to two, then some other fraction will result.

<sup>579</sup> Plotted on a double logarithmic scale with size rank as one co-ordinate and amount of population as the other co-ordinate the theoretical distribution of individual cities appears as a straight line at an angle of 45 degrees. If the gradient is not unity then the slope of the straight line would be at some different angle.

<sup>580</sup> Davis, *World Urbanization, 1950-1970* ... vol. 2 (1972), pp. 17-28. The characteristics of the upper open-ended category of 8 million or more inhabitants are rather accidental because such cities are very few, and none of them can be considered as the world's chief centre.

<sup>581</sup> Beckmann, "City hierarchies and the distribution of city size" (1958). Paar, in "City hierarchies and the distribution of city size ..." (1969), criticized Beckmann's formulation, and maintained that a correct formulation would have led him to conclude that city hierarchies are not compatible with the rank-size rule. Beckmann and McPherson, "City size distribution in a central place hierarchy ..." (1970), again assert that the central place model is consistent with the rank-size rule.

<sup>582</sup> This has been shown for the United States by Duncan, "Population distribution and community structure" (1957), p. 365; and by Schnore and Varley, "Some concomitants of metropolitan size" (1955).

ever, that at the present time there is insufficient evidence to support such a conclusion.<sup>583</sup> None the less, it seems clear from the experience of many nations that the spatial relationship of the various elements of the economy is an extremely important factor influencing the over-all process of national development. Vapnarsky, for example, shows how the structure of city sizes within Argentina has been affected by strong economic relationships with other nations and weak internal linkages. During its colonial period, there was a tendency towards heavy concentration in the national capital and an obvious lack of middle-size cities. As the economy achieved greater internal integration, the urban structure reflected this in a movement towards the norm indicated by the rank-size rule.<sup>584</sup> Within this context, it must be concluded that the structure as well as the level of urbanization is an important consideration.

### E. Policies and programmes affecting urban and rural population distribution

245. A number of types of policy strategies and programmes have come into evidence with respect to urban and rural population distribution in response to the special problems that have to be faced in the current development of urban and rural areas. In this section, the types of problems prevailing in urban and rural areas are briefly summarized and some illustrations are given of policy strategies that have been formulated in response to prevailing conditions.

246. Problems of rural poverty have always existed—until recently the world habitat was mostly rural and it was technologically not yet significantly developed. For the bulk of the population living conditions superior to mere subsistence were hardly attainable. Rural settlement patterns were closely tied to conditions of soil fertility and climate. Three circumstances are new with regard to the present condition of rural areas. First, there is an unprecedented overcrowding of rural population in many of the developing nations where fertility rates are still high and urban employments have not yet sufficiently developed to absorb the surplus rural population. Secondly, and conversely, in the more developed nations many rural areas suffer problems of depopulation.<sup>585</sup> For instance, such a densely settled nation as Japan has experienced problems with regard to rural depopulation.

<sup>583</sup> Berry, "City size distributions and economic development" (1964). See also the discussion in Richardson, *Regional Economics* (1969), pp. 183-184.

<sup>584</sup> Vapnarsky, "On rank-size distributions of cities ..." (1969).

<sup>585</sup> For discussions of rural depopulation and its demographic and socio-economic consequences in France and selected areas of the United States, see Locoh, "La population des ménages agricoles ..." (1970); and Loomis and Beegle, *Rural Sociology* ... (1957). Weber, in *The Growth of Cities in the Nineteenth Century* ... (1899; 1963 ed.), p. 230, notes that instances of rural depopulation in France due to rural-to-urban migration can be traced back in history at least as far as the writings of Quesnay and other eighteenth century physiocrats. Gravier, *Paris et le désert français* (1947), p. 28, observes that the majority of rural cantons in France had already reached their maximum, or near maximum, population size by the census of 1851. In cantons which remained rural, an average population decrease of 25 per cent was registered between 1851 and 1936.

Thus, between 1960 and 1965, 27 out of 46 prefectures in Japan lost population, and smaller cities experienced declines during the same period while larger cities increased greatly.<sup>586</sup>

247. Thirdly, the spatial distributions of agricultural activities and settlements have come increasingly to be influenced by the urban settlement patterns rather than soil fertility. The intensity of agriculture is greatest near large cities and declines with distance from cities even though the soil quality close to large cities is not necessarily better than that in less accessible areas.<sup>587</sup>

248. Modern cities differ from ancient cities chiefly in scale and in the degree of integration of their economic functions. One reason why the great cities of the ancient world could not attain a very large size was that they had neither the lateral nor the vertical transportation capabilities of modern cities. Rome was one of the large cities of the ancient world. As the population of imperial Rome increased, the common people were crowded together in ever-increasing congestion. Apartment houses rose to six or eight floors.<sup>588</sup> The inhabitants had to carry out their varied functions within feasible walking distance. The streets were very narrow. Vehicular traffic within the city was prohibited during day-time. Thus, the population potential of the ancient cities was limited as compared with modern possibilities.

249. The modern city is favoured by various new forms of transportation. Vast networks of highways and train tracks, some of them underground, facilitate the movement of both passengers and freight within large metropolitan agglomerations and between them. Large systems of satellite cities have arisen.<sup>589</sup> Moreover, the capacity for concentration of population in the central metropolis has been increased by the development of high-rise buildings in which vertical transportation is provided by elevators.<sup>590</sup> Some of the occupancy in high-rise buildings is not residential, but rather a concentration of daytime office workers.

250. The variety of experience in different nations, at different levels of development and under varied circumstances has led to a wide spectrum of planning strategies.

<sup>586</sup> Japan, Bureau of Statistics, *Showa 40-nen Kokusei Chosa* ... (1970), pp. 6-25, 236-237 and 252-253. Rural depopulation in Japan became intense after 1955. Prior to 1955, only a few prefectures suffered population losses.

<sup>587</sup> Hathaway, Beegle and Bryant, *People of Rural America* (1968) and also Duncan *et al.*, *Metropolis and Region* (1960), pp. 180-196 and 557-559. In a correlation analysis (p. 190), the authors found a negative relationship between an index of soil quality and rural-farm population density. See also von Thünen, *Der isolierte Staat* ... (1826; 1875 ed.).

<sup>588</sup> Hilberseimer, *The Nature of Cities* ... (1955), p. 70.

<sup>589</sup> Schnore has written extensively on the subject of metropolitan decentralization in the United States. See, for example, *The Urban Scene* ... (1965); *Class and Race in Cities and Suburbs* (1972); "Municipal annexations ..." (1961); "Metropolitan development in the United Kingdom" (1962); "On the spatial structure of cities in the two Americas" (1965); Schnore and Petersen, "Urban and metropolitan development ..." (1958); and Schnore and Klaff, "Suburbanization in the sixties ..." (1972).

<sup>590</sup> According to Gottmann, the first passenger elevator officially recorded was installed in 1857 in a not very high building in New York City. Gottmann, "The skyscraper amid the sprawl" (1967), pp. 127-128.

A systematic review of these policies is clearly beyond the scope of the chapter. An attempt is made, however, to cite a number of examples out of the diversity of opinion and practice.<sup>591</sup>

251. The discussion below is organized under the following headings: (1) return of rural migrants, (2) rural development, (3) decentralization of industry, (4) construction of new towns, (5) development of growth poles, and (6) redevelopment of the big city. These headings represent different policy measures which have been adopted to deal with population excesses in urban areas resulting from rural-urban migration. But policy systems actually in existence cannot be so simply classified. Some combination of several types of policy is followed in many countries. Often theoretically diverse policies are emphasized among different regions of the same nation where different circumstances prevail. For example, there may be policies for the simultaneous development of both new towns and existing growth centres within the same country. While new towns are theoretically quite different from growth centres, they are often empirically indistinguishable.

252. Administrative and legislative measures directly affecting rural-urban migration have been introduced in few countries only, but indirect measures which can encourage or discourage migratory flows are widely applied. Aside from legislation ensuring orderly development and growth of cities and other settlements, several Governments provide cities and local governments with technical and financial assistance and create special organizations or departmental units responsible for various aspects of urban development. Eventually, widely ramified systems concerned with urban and regional planning can result.

253. A good example of legislation in this area is provided by the United Kingdom, where legislation regarding city planning began as early as 1848, being incorporated in the Public Health Act of that date. The Royal Commission on the Distribution of the Industrial Population, appointed in 1937, examined the factors affecting the geographic distribution of industry, its probable change in the future, and the desirability of remedial measures.<sup>592</sup> The findings of that Commission were eventually reflected in the Distribution of Industry Act<sup>593</sup> and to some extent in other legislative acts regarding town and country planning which also have a profound meaning for the migration and redistribution of population.<sup>594</sup>

254. Similar indirect legislative measures have been introduced in many other countries.<sup>595</sup> On the basis of such acts, regional and master plans are prepared for selected areas and cities, which in more distinctive ways

set forth population policies for the regions under consideration. Another good example is the Regional Plan of the Paris region, which recommends the limitation of population growth in the region to 100,000 a year.<sup>596</sup> This recommendation was approved by the Government.<sup>597</sup> The French Government had earlier adopted a policy of decentralization of industry, which was at least partly aimed at easing the population pressure on the region of Paris.<sup>598</sup>

## 1. RETURN OF RURAL MIGRANTS

255. Among the most direct measures adopted by some countries to stem urbanization has been the attempt to dissuade rural migrants from going to urban centres, or to organize their return to the villages. Both the economic and social costs of maintaining surplus labour are much greater in the cities than in the countryside. Examples of such action occurred in the presently modernized countries at earlier stages of development. The extension of Paris beyond certain limits was prohibited by law in 1549, 1554, 1560, 1563, 1564, and 1672.<sup>599</sup> In the time of the later Tudors and Stuarts, proclamation after proclamation was issued forbidding the erection of new houses in London and enjoining the country people to return to their homes.<sup>600</sup> Similar proclamations are currently being issued in Africa. Often the jobless are forcibly removed from the cities.<sup>601</sup>

256. The economic and social disadvantages of the mammoth urban aggregation have often been debated, and it has sometimes been suggested that the population of metropolitan areas should be restricted by law and migration stopped by police action. But police measures are difficult to enforce where migration movements are motivated by economic necessity.<sup>602</sup> In general, policies of direct control over internal redistribution of population (by restricting the right of migrants to travel and settle in the cities or by forcing them to return to the country) have not been considered either feasible or desirable in the countries with market economies.<sup>603</sup>

<sup>596</sup> France, Ministère de la construction, *Plan d'aménagement et d'organisation générale de la région parisienne* (1960), p. 102.

<sup>598</sup> France, Ministère du logement et de la construction, "Décret N° 55-36 du 5 janvier 1955 tendant à favoriser une meilleure répartition des industries ..." (1955).

<sup>599</sup> Weber, *The Growth of Cities in the Nineteenth Century ...* (1899; 1963 ed.), p. 454.

<sup>600</sup> *Ibid.*

<sup>601</sup> Hance, *Population, Migration, and Urbanization ...* (1970), pp. 277-278. In Niger, for example, a 1962 law specified that all unemployed urban youths must either perform some service or return to their villages. Moreover, the police were reported to have rounded up such youth in Niamey and sent them back to the country. *Ibid.* and Thompson, "Niger" (1966), p. 178.

<sup>602</sup> Koenigsberger, "Regional planning in Asia" (1959), p. 118.

<sup>603</sup> Medina Echavarría and Hauser, "Rapporteurs' report" (1961), pp. 25-26, noted that the development of urbanization in the advanced countries was haphazard and regulated only by spontaneous market forces. On the effectiveness of controls, see Ponsioen, "An analysis of—and a policy regarding—rural migration ..." (1967), p. 520.

<sup>591</sup> A collection of articles describing planning policies in many different areas of the world appears in United Nations, *Planning of Metropolitan Areas and New Towns* (1969).

<sup>592</sup> United Kingdom, Royal Commission on the Distribution of the Industrial Population, *Report* (1940), pp. vii-viii.

<sup>593</sup> United Kingdom, "Distribution of Industry Act" (1945).

<sup>594</sup> United Kingdom, "New Towns Act" (1946); "Town and Country Planning Act" (1944) and (1947).

<sup>595</sup> For example, Poland, "Ustawa z dnia 31 stycznia 1961 r. o planowaniu przestrzennym" (1961).

257. Perhaps the best known examples of regulated migratory movements are provided by centrally planned economies, where the migration of population from rural localities to towns is controlled by the State in the interest of the whole nation and follows a plan.<sup>604</sup> The acute shortage of dwellings as the result of wartime destruction in many of these countries is an added justification for such policies. The public management of dwellings and the compulsory registration of in-migrants and out-migrants are fairly good measures of control and ensure the effectiveness of these policies.

258. A restriction of migration to nearly all the large cities exists in Poland and was introduced shortly after the Second World War. While succeeding in slowing down the stream of migrants to cities which were the subject of limitation, this policy failed to prevent an undesirable, chaotic growth of many settlements and towns in suburban zones. As a result, to obviate further excessive immigration to those towns and settlements, the Government in 1966 extended restrictions on admitting in-migrants to another twenty-six cities adjacent to Warsaw and other urban settlements.<sup>605</sup>

259. An active policy of preventing the influx of peasants into the cities exists in China. A wide variety of measures have been employed, including, for example, the transfer of the surplus population of cities to the countryside and to "hilly areas" to engage in agriculture, forestry and other projects requiring the massive use of labour;<sup>606</sup> requirements of prompt registration by peasants and rural migrants upon entering cities;<sup>607</sup> instructions to agricultural producers' co-operatives to facilitate the readjustment of returned migrants to rural life; and also ideological education in villages to help the rural population appreciate the importance of agricultural production.<sup>608</sup> Critical housing shortages in the cities and the heavy demands for provisions and accommodations were among the reasons cited for the need to control urban population growth.<sup>609</sup> A directive issued by the State Council in 1955 concerning the establishment of a permanent population registration system placed restrictions on rural-urban migration.<sup>610</sup> Again, to prevent the urban population from swelling, a joint directive of the State Council and the Central Committee of the Communist Party was issued on 18 December 1957, which instructed the authorities concerned that they should stop the rural out-flow, turn back those peasants on the road or repatriate those who had already migrated

to the cities.<sup>611</sup> Furthermore, the Household and Population Registration Regulation promulgated by the Standing Committee of the All-China People's Congress on 9 January 1958 defined the conditions under which citizens living in rural areas may move to urban areas.<sup>612</sup> According to Chen, after the Great Leap Forward campaign began in 1958, migration to urban areas was again heavy in response to the opening up of industrial employment opportunities, but when economic conditions became less favourable, the Government took steps to return recent migrants to the villages; especially large numbers were returned to the countryside within a few months in 1961.<sup>613</sup>

260. In December 1968, Mao Tse-Tung called upon educated youths to return to the countryside to be re-educated by the poor and lower-middle peasants. Graduates of urban secondary schools and universities who had not been accepted by the next higher educational institutions, or had not been assigned to a post in industry, educational institutions, or other urban service units were urged to accept rural posts. In contrast with some other programmes in which urbanites are required to spend short tours of duty in the countryside, these youths are expected to settle in a rural village for life.<sup>614</sup>

## 2. RURAL DEVELOPMENT

261. In many countries where urban congestion has become conspicuous, the suggestion has been made that the urban problems might be eased by means of a programme of rural development. By improving rural living conditions and expanding rural and small-town employment, it is thought, the motivation for city-ward migration may lessen and, as a result, cities may grow at a more leisurely pace. There is, however, little evidence that rural development policies have been instituted in very many countries with precisely this aim in mind.<sup>615</sup> However, in Japan following the Second World War, a number of programmes were initiated to develop areas not densely populated where there was sufficient land and natural resources to build up both agricultural and industrial capacity. In practice, these policies were mainly directed towards utilization of relatively abundant land for more agricultural production. Two major programmes, "The post-war Hokkaido development programme" and "The development programmes for specially designated areas", emphasized the intensive development of areas, particularly in the northern regions of Japan, which had a potential for providing an abundance of food, minerals and electric power resources.<sup>616</sup>

<sup>604</sup> Konstantinov, "Rural-urban migration as a factor . . ." (1967), p. 499.

<sup>605</sup> Poland, "Rozporządzenie Rady Ministrów z dnia 11 stycznia 1966 . . ." (1966), p. 57. A list of conditions under which new in-migrants may be admitted is given.

<sup>612</sup> All-China People's Congress, Standing Committee, ninety-first session, "Household and population registration regulation . . ." (1958).

<sup>613</sup> Chen, "Overurbanization, rustication . . ." (1972), pp. 372-373. Other stringent measures adopted have included a food rationing system for urban non-agricultural residents and prohibitions against the recruitment of peasant-immigrants by urban plants and firms. *Ibid.*

<sup>614</sup> Chen, "Overurbanization, rustication . . ." (1972), pp. 365-367.

<sup>615</sup> Medina Echavarría and Hauser, "Rapporteurs' report" (1961), p. 69.

<sup>616</sup> Ito and Sakamoto, *Toshika Jidai no Nihon Keizai* (1967), pp. 181-190.

262. Rural policies adopted in many other countries may have had the incidental effect of slowing down migration to urban areas, though observations are too few to permit generalizations. Some agricultural development measures, such as the introduction of more efficient farming methods, may accelerate out-migration by reducing the demand for labour, while, on the other hand, land settlement projects in sparsely populated rural regions would appear to be more likely to ease urban population growth, since they could provide an outlet for inhabitants of densely settled rural regions and thus an alternative to migration to the cities. The Gal Oya project in Ceylon,<sup>617</sup> the subsidized migration to Mindanao in the Philippines,<sup>618</sup> the transmigration policy in Indonesia,<sup>619</sup> and the development of virgin lands in the Soviet Union<sup>620</sup> are projects of this type.

263. Whereas mechanization in agriculture tends to reduce the needed work force, there are certain forms of agricultural rationalization where even an increased work force may be maintained. Examples are multiple cropping of the same land area, bookkeeping and related activities in connexion with rural co-operatives and agricultural reform, warehousing, local food processing (also tobacco curing, leather tanning etc.), the generation of additional agricultural income upon which local social services may be maintained, and occupations related to the repair and maintenance of improved agricultural machinery. Still, in the majority of situations agricultural improvements alone will probably not by themselves effectively counteract the migratory tendency towards urban areas. Moreover, some local social improvements, notably education (with curricula usually biased by an urban orientation) can have the effect of intensifying urbanward migration by causing potential migrants to feel better prepared to earn their living in urbanized regions.<sup>621</sup>

264. In industrially advanced countries, especially the densely inhabited ones, rural developments such as schools, rural electrification, postal, police and fire-prevention services, the local availability of radio and newspapers, the nearness of hospitals and medical services and so forth have brought about living conditions which are no longer so categorically distinct from those in towns and cities as they used to be. These developments, to which may be added the movement of city inhabitants to rural areas in the city's surroundings, the widespread availability of motorized transport, and the general nearness of at least small towns to most rural communities, bring about

an "urbanization"<sup>622</sup> of rural regions where further development may well serve to diminish the rural exodus. These conditions will be found less frequently in sparsely settled countries (where distances from the nearest town are often considerable), and rarely in the less developed countries.

265. For the reasons stated, it is not surprising that a positive policy of rural development for easing the pressure on cities has hardly ever been systematically implemented. The nearest approximations may be either land settlement schemes—though these encounter numerous other problems—or the development of a wide and sufficiently dense network of small towns in proximity to the rural settlements.

### 3. DECENTRALIZATION OF INDUSTRY

266. A number of Governments have taken steps to discourage the further concentration and development of industries in crowded city areas through various regulations affecting the location of industrial units and through the creation around cities of zones allocated for industry. In Pakistan, government policy has encouraged investment, which contributes directly to the building up of infrastructure in rural areas, and priority has been given to industries directly based on agriculture.<sup>623</sup>

267. In India, the third five-year plan specifies that, in so far as possible, new industries should be established away from large, congested cities and in determining new industrial sites, the need for achieving a better regional balance in development should be kept in view.<sup>624</sup> China has actively pursued a policy of transfer of population from old urban centres to new towns (e.g. in the sparsely populated north-western province of Shansi) which are expected to develop into dynamic points of industrial growth and thereby ease the urbanization problems of the older metropolitan centres. A number of new industrial cities are reported to have sprung up in the interior of China during the past ten years as a consequence of this policy.<sup>625</sup>

268. Very active policies of decentralization and deconcentration of industry are applied in such countries as Hungary,<sup>626</sup> Poland<sup>627</sup> and the Soviet Union.<sup>628</sup> For example, in Poland, in addition to the employment limits set for industrial plants in big urban centres and the

<sup>622</sup> i.e., the attainment of a degree of "urbanism" in the sociological and cultural meaning of the word, though not necessarily in the form of settlement.

<sup>623</sup> United Nations, Economic Commission for Asia and the Far East, *Report of the Expert Working Group on Problems of Internal Migration and Urbanization* ... (1967), p. 44.

<sup>624</sup> India, Planning Commission, *Third Five Year Plan* (1961), pp. 144, 148.

<sup>625</sup> See, for example, New China News Agency, "Construction of cities along Szechwan-Sikang, Sikang-Tsinghai and Sikang-Tibet highways" (1953); New China News Agency, "Great achievement in city construction in China" (1956); and New China News Agency, "Building construction grows in cities" (1956).

<sup>617</sup> See the description in Koenigsberger, "Regional planning in Asia" (1959), p. 121.

<sup>618</sup> The Governments' efforts at giving desired direction to migration are said not to have been particularly successful, however. United Nations, Economic Commission for Asia and the Far East, *Report of the Expert Working Group on Problems of Internal Migration and Urbanization* ... (1967), pp. 46-47.

<sup>619</sup> *Ibid.*, p. 45.

<sup>620</sup> Konstantinov, "Rural-urban migration as a factor ..." (1967), p. 503.

<sup>621</sup> Caldwell has noted, for example, that in Ghana the imported educational system, with its content oriented towards advanced societies, appears to prepare persons only for life in the towns. Caldwell, "Determinants of rural-urban migration ..." (1968), p. 369.

required licensing of new ones, some existing plants or certain of their branches have been transferred from Warsaw to quite distant small cities in rural regions.

269. The decentralization of industry and the construction of new cities are very often based on regional development plans. It should be made clear, however, that due to the complexity of regional plans, their role as a tool in an internal migration policy may vary, depending on the kind of plan. As a rule, regional plans for metropolitan areas or already heavily industrialized areas are aimed at checking the flow of migrants and at the decongestion of cities, whereas regional plans like multi-purpose river valley plans or depressed areas regional plans create favourable conditions for an influx of migrants or a slackening of emigration.<sup>629</sup> Typical of the first group is the regional plan for Paris,<sup>630</sup> the Randstad Plan in Holland,<sup>631</sup> the regional plan of the Upper Silesian Industrial District in Poland;<sup>632</sup> on the other hand, the Regional Plan for Southern Italy,<sup>633</sup> and the Guyana Programme in Venezuela, are examples of the second type of regional plan. As a tool of internal migration policy, the latter programme is helping to relieve population pressure in areas that have limited prospects for development, in addition to diverting some of the flow of migrants from the central region of Venezuela.<sup>634</sup>

#### 4. CONSTRUCTION OF NEW TOWNS

270. One of the recently much advocated measures to check migration to large cities and metropolitan areas is the building of new urban settlements. The new towns type of policy is associated with the development of small, insulated urban settlements which are self-sufficient with respect to employment, shopping, community facilities etc.<sup>635</sup> Quite logically such activities are generally connected with policies of decentralization of industry. The idea of new towns developed in Britain as a reaction against the nineteenth-century metropolis. Later with the enactment of the New Towns Act by Parliament in 1946, the building of new comprehensively planned cities was undertaken as a measure to curb the growth of London, to provide a more effective pattern and method for metropolitan growth,<sup>636</sup> and to prevent the depopulation of the rural areas.<sup>637</sup> New towns have been or are being built in other countries as well. Partly to arrest movement to large cities of Western Holland, there has been established the new city of Emmen in north-east Holland. To slow the growth of Mexico City, a new town, Ciudad Industrial Bernardino de Sahagún, is being built by the Mexican

Government some sixty miles away. Also the construction of Santo Tomé de Guyana in Venezuela, located about 400 miles from Caracas is expected to relieve some of the pressure of migrants on Caracas.<sup>638</sup>

271. New towns, as a measure to relieve demographic pressure on large cities or to deconcentrate their population, are a prominent feature of planning in the Soviet Union and in Poland. A well-known example in Poland is the new town Nowe Tychy, designed to decrease population pressure on cities of the Upper Silesia Conurbation. Nowe Tychy reached 60,000 inhabitants in 1964 as against the projected figure of 120,000. In the Soviet Union a regional scheme for the Moscow Metropolitan Area provides for some twenty new towns (satellites) with a total of one million inhabitants.<sup>639</sup>

#### 5. DEVELOPMENT OF GROWTH POLES

272. One widely discussed policy with regard to population settlement patterns is based on the growth-pole theory. A large volume of literature devoted to this subject has appeared recently,<sup>640</sup> but unfortunately the term "growth pole" has been used with at least two distinctly different meanings.<sup>641</sup> Inasmuch as the subject of this chapter pertains to spatial distribution and migrations of population, the term is used here to refer to geographic nodes which are attractive for industrial development and population settlement.

273. Growth poles are cities, already existing or planned with the design to grow large enough to serve as "counter-magnets" to continued economic expansion and population settlement in very large cities. Growth-pole cities may be suburban satellite cities within commuting distance of a major metropolis, or they may be developed in isolated regions where it is desired to establish a nucleus for a new regional industrial complex.<sup>642</sup>

274. Like numerous other planners, Friedmann has stressed the benefits to be expected for the combined

<sup>638</sup> Rodwin, "Economic problems in developing new towns ..." (1969), pp. 153, 155.

<sup>639</sup> Malisz, "Physical planning for the development of new towns" (1969), p. 206-207.

<sup>640</sup> An extensive bibliography of English and French literature devoted to growth poles and the related concepts of external economies, agglomeration, optimum size, and certain aspects of regional planning appears in Darwent, "Growth poles and growth centers ..." (1969), pp. 26-31. See also the collection of articles reprinted in Boudeville, ed., *L'espace et les pôles de croissance* (1968).

<sup>641</sup> The term was initially popularized by François Perroux. See his "Note sur la notion de 'pôle de croissance'" (1955); "La firme motrice dans une région et la région motrice" (1961), and "Economic space ..." (1950). The term growth pole is often used to describe the polarity of certain firms or industries in an abstract "economic space", rather than in geographic space. Perroux's theory was of this type. Many recent authors, however (especially planners), have used the term to refer to the polarity of certain geographic nodes which offer sufficient external economies to be relatively more attractive to population and industry than other locations. The range of variation in usage of the term "growth pole" is reviewed in Darwent, "Growth poles and growth centers ..." (1969).

<sup>642</sup> George, *La ville* ... (1952), pp. 215-216, has contrasted the past development experience of pre-existing European cities with that of new cities founded by Europeans in their various colonies (such as Montreal, Chicago, Buenos Aires and Melbourne).

<sup>629</sup> See also the discussion in chapter XVI, section D.

<sup>630</sup> France, Ministère de la construction, *Plan d'aménagement et d'organisation générale de la région parisienne* (1960).

<sup>633</sup> Ginsburg, "Regional planning in Europe" (1969), pp. 137-138.

<sup>634</sup> Friedmann, *Regional Development Policy* ... (1966), chap. 8.

<sup>635</sup> Rodwin, "Economic problems in developing new towns ..." (1969), p. 149.

<sup>636</sup> *Ibid.*

<sup>637</sup> Robson, "New towns in Britain" (1969), p. 168.

functioning of a country's economy by means of growth pole organization of urban settlements. He argues that accelerated urban growth is essential for economic development.<sup>643</sup> During the early phases of economic development, modernization must necessarily be associated with growth in the largest cities. The initial industrial innovations and experiments by small independent *entrepreneurs* could not occur in the absence of external economies available only in cities of significant size.<sup>644</sup> Essential external benefits to the consumer population are also available only in larger cities—such benefits as superior education, more complete libraries and museums, more effective and readily accessible health and medical services etc.<sup>645</sup> However, as the total size of city population increases, the necessity for extreme urban nodality decreases. The initial nodes of urban development become overwhelmingly large and it becomes expedient to consider the planned development of alternative nodes or “poles” of population settlement. To succeed, these growth poles must be large enough to provide the necessary external economies, but small enough to avoid excessive overcrowding of population and industry.<sup>646</sup> Friedmann advocates a policy of accelerated urbanization combined with “concentrated decentralization”.<sup>647</sup>

275. The growth-pole strategy has been applied in many areas of the world. According to Gokhman and Karpov, ideas similar to the growth-pole theory with regard to territorial development were used in the early five-year plans in the USSR.<sup>648</sup> Emphasis has been placed on the planned development of small towns linked with large cities by production, cultural and other ties—that is, “satellite cities”.<sup>649</sup> Recent planning in France has been devoted to the development of seven or eight major regional growth poles designed to reduce the primacy of Paris.<sup>650</sup> During the 1960s, the Japanese government

undertook the establishment of fifteen key industrial centres at strategic sites located in relatively remote prefectures and also promoted the development of medium-size cities up to a million population in these areas. The Government's aims were clearly at proliferating national sub-centres outside the megalopolitan belt on the Pacific Seaboard which can attract a substantial portion of migrants who might otherwise have tended towards Tokyo, Osaka-Kobe and Nagoya.<sup>651</sup> The outcome of these national programmes will not be known for some time to come. According to Ito, however, there have already been some indications of regional convergence in labour productivity and in *per capita* income.<sup>652</sup> Recent slackening in the in-migration into the three metropolitan areas of Tokyo, Osaka-Kobe and Nagoya on the Pacific Seaboard<sup>653</sup> may have been influenced at least partially by the effective formulation and execution of these programmes.

276. As yet there have been few applications of the growth-pole theory in the less developed regions. Hance observed, for example, that there are very few African countries that can afford the luxury of subsidizing the development of new towns or new poles of growth, but he lists roughly fifty existing cities which may have some potential as growth poles.<sup>654</sup> A scheme has been developed for the possible future application of the growth-pole theory in India.<sup>655</sup>

## 6. REDEVELOPMENT OF THE BIG CITY

277. Satellite cities need a centripetal focus—a centre that organizes and co-ordinates the activities within the entire network of economically specialized cities. Already in ancient times, the great cities controlled the economic and political systems of whole empires. In modernized industrial societies the role of the great cities as organizational centres for vast regions of population settlement and economic activity is indispensable. But the ever-increasing size and congestion in the great cities brings ever-increasing social problems. These problems represent the most challenging frontiers for social, economic, architectural, and physical planning innovation.

278. Even if the great cities were not an economic necessity, they would be a spatial necessity. Since the present population of the world is large and increasing, the reduction of *per capita* space available makes some

<sup>643</sup> Friedmann, “The strategy of deliberate urbanization” (1968). Friedmann's earlier contributions are reviewed in Darwent, “Growth poles and growth centers . . .” (1969). See also Hirschman, *The Strategy of Economic Development* (1958).

<sup>644</sup> Jacobs, *The Economy of Cities* (1969).

<sup>645</sup> Although the lack of medical facilities in rural and small-town areas of even modernized nations has often been described as problematical, the lack of medical facilities in the rural areas (relative to urban areas) is especially extreme in developing countries. Arriaga, “Components of city growth . . .” (1968).

<sup>646</sup> Advocates of the growth-pole theory have claimed sizes from 10,000 to 1,000,000 to be optimum. Darwent, “Growth poles and growth centers . . .” (1969), p. 24. The wide range of opinion may arise partly from the fact that in some instances the discussion of growth poles refers to new satellite cities within a metropolitan region, while in other instances it relates to the development of polarity for a metropolitan centre in a poorly developed region.

<sup>647</sup> Friedmann, “The strategy of deliberate urbanization” (1968).

<sup>648</sup> Gokhman and Karpov, “Growth poles and growth centres” (1970), p. 193. The authors note that these ideas were expressed most explicitly by N. N. Kolosovsky and his followers in their writings on industrial territorial complexes. Reference is made on p. 196 of the article to Kolosovsky, *Teoriia ekonomicheskogo raionirovaniia* (1969).

<sup>649</sup> See, for example, several articles published in Davidovich and Khorev, eds., *Goroda-sputniki* . . . (1961).

<sup>650</sup> Growth centres in France, and also in Bulgaria, are described in Bernard, *Les pôles et centres de croissance* . . . (1969). Plans for development of such regional centres (often called *equilibrium metropolises*) as alternative counter-magnets to the Paris region are described in Antoine and Weill, “Les métropoles et leur région”

(1968); Rodwin, *Nations and Cities* . . . (1970), pp. 193-199; and France, Press Information Department of the Embassy, *France: Town and Country Environment Planning* (1965), pp. 14-16. The planned development of several suburban growth poles within the Paris region is described in Hall, *The World Cities* (1966), pp. 89-92.

<sup>651</sup> Various judicial and financial privileges and conveniences were conferred to attract investment by big business. These included a large amount of special grants, funds, and subsidies, and enterprises were promised financial incentives such as tax exemptions and favourable low interest loans. Ito and Sakamoto, *Toshika Jidai no Nihon Keizai* (1967), p. 193; Tachi, Hama and Okazaki, *Mirai no Nihon Jinko* (1970), pp. 58-59; Ito, *Toshika Jidai no Kaihatsu Seisaku* (1971), pp. 52-54 and 127-131.

<sup>652</sup> Ito, *Toshika Jidai no Kaihatsu Seisaku* (1971), pp. 77-83.

<sup>654</sup> Hance, *Population, Migration and Urbanization* . . . (1970), pp. 235-236.

<sup>655</sup> Misra, Prakasarao and Sundaram, *Growth Poles and Growth Centres in Regional Development and Planning in India* (1970).

degree of population concentration inevitable. The problem of spatial congestion varies in different areas of the world, depending on existing densities. Many Western European planners have argued that the optimum population of a city might be about 100,000 or 200,000. Gottmann argues that in Western European nations such as Belgium, France, the Netherlands, and the United Kingdom, there would be little if any agricultural space remaining if the population of these countries were to be dispersed into urban units of 100,000 or 200,000.<sup>656</sup> The Soviet Union, on the other hand, is a more spacious country, although it has much territory which is more or less uninhabitable. According to Lyashchenko, while the Soviet Union will never be threatened with shortage of land to house urban residents, a danger of land shortage exists as a result of increasing industrial construction. As a remedy, he advocated a decisive shift to new production technology consisting of vertical, rather than horizontal, production lines.<sup>657</sup> Such industrial concentration would appear to call for the further agglomeration of population in large cities as a need for a spatially concentrated labour force would arise.<sup>658</sup>

279. Kenneth Schneider has emphasized the need for development of three-dimensional space.<sup>659</sup> Space, as opposed to land, can be expanded through the use of architectural techniques. Schneider argues that the massive low-density horizontal organization of metropolitan space, which has resulted from the use of the automobile, has caused a wide sprawl of population settlement which has resulted in a certain degree of social isolation. "The non-driving half of the population is deprived of normal intercourse with society."<sup>660</sup> Often it is economically irrational to provide adequate public transportation facilities in low-density suburban settlements. Furthermore, the highway arteries themselves consume so much land that the population density becomes even lower.

<sup>656</sup> Gottmann takes issue with a school of French and Belgian architects and urbanists led by Bardet who advocate 200,000 as the optimum size for all cities. He states: "Now, France is not a densely populated country by West European standards, but if the 200,000 figure was adopted as a ceiling for city growth, most of the country would be urbanized; and, with a 100,000 limit, all of it; for the rural areas left between the urbanized districts would just be narrow strips in which the need for intensive agricultural production would probably preclude the undue wanderings of city dwellers. Such a solution applied to the Netherlands, Belgium and Britain, with their much higher average densities, would mean covering their territories with a kind of dispersed city network, within which the specialization of each would cause an incredibly dense traffic between all of them. Thus the generalized 'small-town' solution, even on a modern scale, is bound to produce more congestion and more frustration than ever." See Gottmann, "Urban sprawl..." (1967), p. 11.

<sup>657</sup> Lyashchenko, "Zemlia i gorod" (1967).

<sup>658</sup> The desirability of large cities is a much-debated question in the Soviet Union. For articles which criticize on economic and social grounds existing policy to restrict the growth of large cities see, for example, Baranov, "Bolshoi gorod, ego segodnia i zavtra" (1967); Perevedentsev, "Goroda i gody" (1969), and his "Kakoi gorod vygoden?" (1967). Other authors, however, argue that small and medium-size cities should be restricted. Khorev, "Kakoi gorod nuzhen?" (1969), and his *Gorodskie poseleniia SSSR*... (1968), especially pp. 95-214.

<sup>659</sup> Schneider, "The destruction of urban space" (1970).

<sup>660</sup> *Ibid.*, p. 66. According to Hawley, *Urban Society*... (1971), p. 146, the introduction of the automobile increased the local area within an hour's travel distance from the city centre from about 100 to 2,000 square miles.

280. In the Soviet Union, where private automobile ownership is less common than in many modernized nations,<sup>661</sup> urban sprawl has resulted in overloading of public transportation facilities and severe commuting strains on the part of workers who must commute either to a central city or another suburb. It is said that cities of the USSR far outrank the cities of other countries in passenger loads.<sup>662</sup>

281. Schneider has suggested that various related functions can be vertically organized in order to gain once more the horizontal space needed to make unobstructed pedestrian movement feasible.<sup>663</sup> If more population and economic activities were located in high-rise structures, there would also be more land for parks and other recreation areas essential for the well-being of the urban resident.<sup>664</sup> By concentrating more people in a smaller area of horizontal space, one would assume that high-rise structures could also be a means of relieving the pressures of urban sprawl, provided that they are effectively designed for human convenience.<sup>665</sup>

282. While evidence in favour of redevelopment of existing major metropolitan centres, even at heavy expense, appears to be clearly established in modernized nations, it is not so clear what policy alternatives should be adopted in some of the smaller developing countries where a single giant city, the so-called "primate city",

<sup>661</sup> Statistics shown in one source indicate that in 1960 there were 333 inhabitants per car in the Soviet Union, whereas there were less than 25 inhabitants per car in other European countries listed and only 3 in the United States. See Barzanti, *The Underdeveloped Areas*... (1965), p. 408.

<sup>662</sup> Sukholutsky, "Gorod i transport, ili otritsatelnye storony dostoinstva" (1968). Many commuters to Moscow spend an hour and a half or two hours (and sometimes even more) en route to work every day from the suburbs, and some come from suburbs 100 or more km away. Perevedentsev, "Goroda i gody" (1969).

<sup>663</sup> Schneider, "The destruction of urban space" (1970); Doxiadis has also written about the necessity for providing smaller territorial units of human pedestrian scale within the larger units of metropolitan organization. Doxiadis, *Ekistics: An Introduction to the Science of Human Settlements* (1968). The arguments are summarized in his "Ekistics, the science of human settlements" (1970) and in numerous articles which have appeared in the journal *Ekistics* which he edits. Svetlichny also stresses the need for preserving possibilities for pedestrian movement within a highly developed mass transportation system. See his article entitled "Gorod zhdët otveta" (1966). In a similar vein, Schneider visualizes a "metropolis of concentrated communities" containing high rise, multi-purpose structures and punctuated by broad expanses of open spaces between communities. Schneider, "The architecture of urban space" (1971), p. 50.

<sup>664</sup> A number of visionary models for efficient use of three-dimensional space (underground as well as overhead) have been developed, some of them involving designs for cities of as many as 50,000,000 inhabitants. See, for example, Driazgov, "Krizis plenokhnykh gorodov i trëkhmernyi gorod budushchego" (1968). See also Arsène-Henry, "La ville de l'an 2000" (1972); and Brugmann *et al.*, *The Ultimate Highrise* (1971). Lyashchenko has also described various models for the future in his "Zemlia i gorod" (1967).

<sup>665</sup> Not everyone agrees with the anti-sprawl view. Fagin writes: "... the kind of urban flow we've had is not necessarily bad, even though on an aerial photograph it may not appear at all orderly. After all, most of the people living in the urban amoeba's little feet do not judge life there by whether there is a neat exterior geometric shape. The question of how they do judge life has to do with the conditions they experience within the metropolis, not its bounding form. There is not yet proof that high density and centrality are conducive to the better life..." See Fagin, "Sprawl and planning" (1967), p. 153.

exists without a network of satellite cities. One of the more extreme examples is Thailand. In 1967, the population of Greater Bangkok was estimated to be 2,600,000—32 times as large as the population of the second largest city of Chiangmai.<sup>666</sup> The degree of primacy in Bangkok is increasing, rather than decreasing. In 1947, it was only 21 times as large as Chiangmai and in 1960, it was 27 times as large as Chiangmai. Whether it is better to allow Bangkok to grow at the expense of other cities or whether it is economically a sound idea to promote industrial activities and settlement in other locations is a complex problem to which there is no simple answer. Certainly, each such case will have to be evaluated in terms of the individual situation at hand, many factors being taken into account.

283. Perhaps the emergence of a modern territorial organization of population settlement in systems of satellite cities will have to await the emergence of a modernized industrial system—one in which activities are organized by large enterprises. In countries where industrial firms have grown large, many internal economies are possible: a big firm can absorb within it all the needed specialists. The firm is then enabled to move to satellite cities or new

outlying industrial parks where space is less expensive and wages are lower. This process, as it occurs in New York City, has been described by Raymond Vernon<sup>667</sup> and later by Jane Jacobs.<sup>668</sup>

284. Where a high degree of primacy exists in developing countries, the situation may be quite different. Technological improvements may not be introduced rapidly, firms may not grow in size or seek outlying locations. In such cases, policies designed to relocate industries away from the great cities must be carefully considered from the point of view of economic feasibility.

285. Because of land shortage, high local costs and the technical standards necessitated, redevelopment of a big city is an expensive and time-consuming operation. The need for redevelopment creates periodic financial crises even in highly developed countries, but much more acute problems in some of the less developed countries, where the fastest city growth is occurring and financial means for renewal are particularly limited.

## INTERNATIONAL MIGRATION

1. Various aspects of migration and population redistribution occurring within national boundaries have been discussed in the preceding chapter. Population movements which cross national boundaries merit special treatment because such movements are usually regulated by legal provisions and policies of the countries involved. Moreover, a country's net migration balance, being one of the components of its population growth, must be assessed in any analysis of population growth trends.

2. Migrations across international boundaries, whether voluntary or forced upon peoples by famine, conquest or other disasters, are known to be as old as history, but there was little precise information on the size and nature of such movements before the nineteenth century. Even today, very little is known about the volume of some intracontinental movements, such as those of African populations, though the directions of the main movements have been charted. There are also some startling gaps in the migration statistics of the most advanced countries; thus, Canada keeps no emigration statistics and the United Kingdom, until recently, kept no statistics relating to international movements by air.

3. Migration statistics are prepared primarily for national purposes, and international comparability is often difficult to achieve.<sup>1</sup> While international standards have been recommended for the collection of migration statistics,<sup>2</sup> no compilation of comparable data on a world-wide basis has yet been possible.<sup>3</sup> In fact, even among European countries and countries in which European migrants have settled, few have adopted international standards.<sup>4</sup> Analysis of international migration must therefore be based in part on statistics of passengers on ships and aircraft, statistics of work permits, and data from population censuses, rather than on migration statistics as such.<sup>5</sup> Sometimes only the net migratory balance can be calculated for a particular country, the far greater gross movements both in and out of the country

never having been tabulated. In other instances, the data collected pertain to movements in one direction only and, hence, the net balance of movements is unknown. There are also difficulties in differentiating between long-term migration and changes of residence of relatively short duration, and it is only recently that attempts have been made to establish a common terminology.<sup>6</sup>

4. The forces which impel people to migrate across international boundaries are often similar to those discussed in the preceding chapter which bring about internal movements. Many international movements proceed from rural areas in one country to urban areas in another, thereby displaying some of the features of rural to urban migration within a country. The economic and social effects of both types of migration are also often similar, as might be expected in view of the artificiality of distinctions based on national boundaries. Movements which constitute international migration in a continent of many small nations, such as Africa, are in many respects the equivalent of internal movements in countries of vast size and geographical variety, such as India or the USSR, where distances covered and differences in topology and environment may sometimes be even greater than those involved in international movements. Because of the considerable diversity of international migrations, it is often convenient for analytical purposes to distinguish transoceanic or intercontinental movements from those occurring within continents.

5. The chapter first summarizes the principal migratory trends of recent times in different regions of the world. It then discusses the economic and other factors which have influenced migratory streams, including also government policies in this field. The final sections of the chapter are devoted respectively to the demographic, economic and social effects of migration.

## A. Migration trends in recent times

## 1. INTERNATIONAL MIGRATIONS OF EUROPEANS

6. It is an outstanding fact in the history of international migrations that certain large regions, notably the Americas and Oceania, have remained virtually a preserve for migrants originating from Europe. In most of the coun-

<sup>1</sup> For a general discussion of the problems of improving migration statistics, see Thomas, *International Migration and Economic Development* ... (1961), pp. 19-24; United Nations, *Problems of Migration Statistics* (1949).

<sup>2</sup> United Nations, *International Migration Statistics* ... (1953).

<sup>3</sup> United Nations, "A survey of intercontinental migration in the post-war period" (1955), vol. 2, p. 261.

<sup>4</sup> Intergovernmental Committee for European Migration, Joint Statistical Project on European Migration, *A Decade of Post-World War II European Migration* ... (1959), pp. 3-5.

<sup>5</sup> Some important advances have been made in the utilization of population census data for analysing migration trends. See, for example, Kuznets and Rubin, *Immigration and the Foreign Born* (1954); Keyfitz, "The growth of Canadian population" (1950); McDougall, "Immigration into Canada ..." (1961).

<sup>6</sup> Permanent or long-term immigrants are for international purposes defined as those intending to remain for more than one year; temporary or short-term immigrants are non-residents intending to take up a remunerated occupation for one year or less. See United Nations, *International Migration Statistics* ... (1953), p. 17.

tries of overseas settlement, legislation was enacted to exclude immigrants from Asia, particularly from East Asia, soon after such migrants began to appear in significant numbers. Hence, a potentially large migration of Asians to these areas was prevented from developing.

7. It has been estimated that more than 60 million Europeans had emigrated overseas from the beginning of colonization movements up to the outbreak of the Second World War.<sup>7</sup> In the post-war period, between 1946 and 1963, there was a gross movement out of Europe of about 10 million people, with a net loss of 7 or 8 million.<sup>8</sup> The main features of European migrations since the Napoleonic Wars have been:<sup>9</sup>

(a) The major role of the British Isles (the United Kingdom and Ireland) as a source of overseas emigration throughout the whole period, with the number of emigrants averaging more than 150,000 annually between 1846 and 1963;

(b) The much less steady, although considerable, contribution of Germany, with the last four decades of the nineteenth century as the peak period;

(c) The large size of the total migratory flow from Europe in the fifteen years before the First World War, mainly as a result of a new outpouring from Southern and Eastern Europe, including Russia. During this period, the average annual emigration from Europe as a whole was well in excess of one million persons, a figure not reached before or since;

(d) The decline of overseas European migration between the world wars, arising partly as a result of restrictions on immigration by the overseas countries of settlement, but aggravated by the repercussions of the world depression of the early 1930s, which sent some movements into reverse. From 1921 to 1939 the average annual number of emigrants overseas was about 375,000;

(e) The large-scale compulsory transfers of population in Europe at the end of the world wars, and particularly after the Second World War, followed by the substantial recovery of gross voluntary emigration to levels much above those of the interwar period, though well below those of the years immediately preceding the First World War;

(f) The post-war increase in international migration within Europe, which has resulted in complicated patterns of migration, with many European countries, such as the Federal Republic of Germany, the Netherlands and the United Kingdom, not only sending emigrants abroad, but also drawing immigrants in from other parts of Europe and from abroad.

#### (a) Overseas emigration of Europeans to 1940

8. From 1820 to 1940 some 32.6 million migrants went to the United States from Europe.<sup>10</sup> Up to and including the 1880s the great majority of the migrants to the United States came from the British Isles and Germany, with sizable numbers also from Scandinavia; after 1880, immigration from Southern and Eastern Europe assumed greater importance, and between 1890 and 1920 the numbers coming from these regions exceeded by a considerable margin the numbers from Western and Northern Europe.<sup>11</sup> Over the whole 121-year period, Germany provided over 6 million immigrants, and Italy, Ireland, Great Britain and Austria-Hungary each between 4 and 5 million.<sup>12</sup>

9. Other parts of the American continent took most of the remainder of Europe's emigrants.<sup>13</sup> Some 6.7 million emigrants appear to have gone to Canada between 1851 and 1941, with 4.6 million arriving between 1901 and 1931, but included in these totals are a large number coming from the United States.<sup>14</sup> The number of emigrants from Canada was also very high, however, falling not far short of the number of immigrants during this ninety-year period; most of the emigrants went to the United States.<sup>15</sup>

10. From about 1880, immigrants began to enter Latin America in large numbers, the bulk coming from Southern Europe. One estimate places immigration to Argentina between 1857 and 1940 at 6.6 million, and that to Brazil between 1821 and 1940 at 4.7 million, the great majority

<sup>10</sup> Taeuber and Taeuber, *The Changing Population ...* (1958), pp. 53, 57. Official records of the number of immigrants were not kept prior to 1819, but estimates suggest that less than a quarter of a million immigrants entered the United States from 1790 to 1819. *Ibid.*, pp. 50-51.

<sup>11</sup> *Ibid.*, pp. 55-61. For a history of emigration from the British Isles, see Carrothers, *Emigration from the British Isles ...* (1929); Ireland, Commission on Emigration and other Population Problems, 1948-1954, *Reports* (1955), chap. 7; Walshaw, *Migration to and from ...* (1941); Shepperson, *British Emigration to North America ...* (1957). See also Burgdörfer, "Migration across the frontiers ..." (1931); Thomas, *Social and Economic Aspects ...* (1941); Ratti, "Italian migration movements ..." (1931).

<sup>12</sup> Taeuber and Taeuber, *The Changing Population ...* (1958), p. 56. Among the most significant of the many sociological and historical studies of the great transatlantic migration, which supplement the essentially statistical studies, are Hansen, *The Atlantic Migration ...* (1940); Foerster, *The Italian Emigration ...* (1919); Handlin, *Boston's Immigrants, 1790-1865 ...* (1941); Thomas and Znaniecki, *The Polish Peasant ...* (1958).

<sup>13</sup> Isaac has calculated that of a total of about 60 million European emigrants, nearly 60 per cent went to the United States, 11 per cent to Argentina, about 8 1/2 per cent to Canada, 7 1/2 per cent to Brazil, 5 per cent to Australia, 1 1/2 per cent to South Africa, and 1 per cent to New Zealand. These figures appear to refer to the period from about 1815 to 1932. See Isaac, *Economics of Migration* (1947), p. 62.

<sup>14</sup> See Keyfitz, "The growth of Canadian population" (1950), p. 48. During the period from 1908 to 1920, when about 2.5 million immigrants entered Canada, more than a third were from the United States, and over three-fourths of these were United States citizens. Ferenczi, "Introduction and notes" (1929), p. 366; Coats and Maclean, *The American-born in Canada ...* (1943), p. 50.

<sup>15</sup> Keyfitz, "The growth of Canadian population" (1950). See also Coats and Maclean, *The American-born in Canada ...* (1943); Truesdell, *The Canadian Born in the United States ...* (1943).

<sup>7</sup> Kirk, *Europe's Population ...* (1946), pp. 72-73.

<sup>8</sup> Data for the early part of the post-war period are given in International Labour Office, *International Migration ...* (1959), pp. 167-168. These figures have been supplemented by information for more recent years collected by the United Nations Statistical Office, or appearing in national publications.

<sup>9</sup> The estimates presented in this summary have been compiled mainly from Kirk, *Europe's Population ...* (1946), p. 279; International Labour Office, *International Migration ...* (1959); and national sources.

of these immigrants having arrived between 1881 and 1930.<sup>16</sup>

11. Another significant stream of Europe's migrants went to the British colonies and dominions, particularly Australia, New Zealand and South Africa.<sup>17</sup> Australia and New Zealand together appear to have absorbed about 2.3 million settlers in the period 1801-1935, most of them from the British Isles.<sup>18</sup>

12. Throughout much of the nineteenth century there was a high degree of complementarity between the sending and receiving countries. The settlement of the immigrants on the land was facilitated by land grants, and assisted passage schemes were in operation in Australia and New Zealand (see section B.2 below). A variety of factors, such as the decrease of the size of farms through inheritance or other reasons, as in southern Germany, Austria and Norway,<sup>19</sup> the consolidation of small holdings, as in England,<sup>20</sup> and increasing productivity, all tended to create surpluses of rural labour within Europe. The most acute pressures occurred in Ireland where absentee land-holding, rapid population increase and the potato famine of 1847 brought the people to destitution.<sup>21</sup>

13. By the latter part of the nineteenth century the heyday of land settlement was over in the United States. Investments in North America and the British colonies in particular, both from domestic capital and from foreign lending, especially from Britain, were going increasingly into railways, manufacturing and urban housing. There were temporary set-backs in the immigrant countries following excessive borrowings or withdrawals of overseas investments, but generally the economic factors favouring the New World were overwhelming. The high productivity of overseas farming, especially in the United States, was outstripping that of the European farmer, thus bringing a crisis to agriculture throughout Europe and thereby creating a further "push" factor making for increased emigration. These economic factors were operating at a

time when many of the European populations were reaching their maximum rates of natural growth, around 1 per cent per year.<sup>22</sup> These were the conditions behind the great outflows from the 1880s to the outbreak of the First World War. The great bulk of the immigrants, especially from continental Europe, continued to come from the peasantry, but they now found employment in railway construction, in mines and in the growing industries, rather than in rural occupations.

14. The war of 1914-1918 ushered in many changes which were to militate against international migration. The United States Quota Act of 1921 and the Immigration Act of 1924 severely restricted immigration, particularly that coming from Southern and Eastern Europe.<sup>23</sup> As a result of the general deterioration of economic conditions, British emigration to other parts of the Empire also decreased during the 1920s, despite the Empire Settlement Act of 1922 which aimed to maintain the flow of people from the United Kingdom.<sup>24</sup> In the ten years 1922-1931, over 400,000 emigrants were assisted under the scheme, most of them going to Australia and Canada.<sup>25</sup> The main attraction for British emigrants during this period continued to be North America, but the flow was less than half that of the 1880s.<sup>26</sup>

15. Southern Europeans, deflected from the United States after 1924, continued to find some outlet to Latin America, but opportunities were restricted by systems of land tenure which prevented most of the settlers from acquiring cheap land and by the inadequacy of domestic capital for the development of transport and productive plant. Many of the immigrants went to urban areas, where the attractions were limited because of low wages, inadequate housing and, frequently, political instability.<sup>27</sup>

16. The war had also brought a marked change in the pattern of international investments, with capital now flowing from the United States into Europe, and particularly Germany,<sup>28</sup> thus tending to decrease the incentives for emigration overseas. The collapse of the boom in the American economy and the onset of the world depression by 1930 virtually brought European overseas emigration to a halt until after the Second World War. Economic factors were undoubtedly the most important determinants operating in the 1930s to restrict the flows of international migration, but these were backed by immigration

<sup>16</sup> United Nations, *Economic Survey of Latin America, 1948* (1949), pp. 155-157. For other estimates of immigration into Latin American countries, see the following United Nations publications: *Immigration in Brazil* (1950), p. 64; *Immigration in Chile* (1950), table 62. See also Avila, "Brazil" (1958).

<sup>17</sup> See, for example, the following studies of immigration to these countries: Borrie, "Immigration" (1958); Forsyth, *The Myth of Open Spaces ...* (1942); Phillips and Wood, eds., *The Peopling of Australia* (1928); Cruickshank, "New Zealand—external migration" (1931); Carrothers, *Emigration from the British Isles ...* (1929); Robertson, "South Africa" (1958).

<sup>18</sup> Landry, *Traité de démographie* (1949), p. 471; Kirk, *Europe's Population ...* (1946), p. 90. Estimates for South Africa are more difficult to compile, since no records of immigration and emigration as such were kept before 1924. Katzen, "South-African immigration ..." (1963), p. 183. Some estimates for earlier years are given in Davie, *World Immigration ...* (1947), p. 437, but the author believed them to have little validity.

<sup>28</sup> Thomas, *Migration and Economic Growth ...* (1954), p. 200.

restrictions in the receiving countries and by controls on emigration imposed by certain Governments within Europe.<sup>29</sup>

17. The majority of studies produced during the 1930s and early 1940s concluded that there was not likely to be a revival of emigration from Northern and Central Europe, since population decline was projected as the inevitable result of prevailing fertility levels.<sup>30</sup> The response in some European countries to this new demographic situation was to institute pro-natalist social and economic policies.<sup>31</sup> In such circumstances, the overseas receiving countries might have turned for their immigrants to Southern and Eastern Europe where population growth was still relatively rapid, had it not been for the fact that they were at the time struggling to achieve reasonably full employment of their existing populations and were thus unwilling to encourage new inflows.

(b) *Political transfers of European populations after the Second World War*

18. The largest international movements of population ever experienced within Europe—numbering in the tens of millions—occurred during and immediately after the Second World War. During the period when Germany had gained a temporary military dominance over major portions of Europe, large numbers of ethnic Germans residing in countries of Eastern and South-eastern Europe were “repatriated” in line with government policy. Other appreciable ethnic exchanges also took place during the war, as between Poland and the Soviet Union, Romania and Hungary, and Bulgaria and Romania. Running into many millions were the displacements of non-German nationals to participate in the German war effort, and the displacement of other persons, the great majority of them Jews, as a consequence of Nazi racist policies. It has not been possible to measure even with a crude degree of accuracy the gross volume of these movements back and forth across the face of Europe during the chaotic war years, but several detailed studies have dealt with various aspects of the subject.<sup>32</sup>

19. In Western Europe, numerically the most important category of post-war transfers consisted of German populations living mainly in the areas east of the Oder-Neisse line previously administered as part of Germany, and in Czechoslovakia, Hungary and Poland, who had to return within the new German boundaries in accordance with article XIII of the Potsdam Agreement of August 1945.<sup>33</sup>

20. By September 1950, there were over nine million national refugees in Western Germany (with a total population then of 47.7 million), and by 1957 this number had increased to over twelve million. Between 1950 and

1957 there appears to have been a net immigration of approximately 1.6 million from Eastern Germany alone. This massive input to Western Germany exceeded war losses, though the latter had been considerable. While the refugees had higher proportions in the young- and working-age groups than did the remainder of the population, the population structure of Western Germany was still far from “normal” by 1950.<sup>34</sup> About three and a half million German nationals had been transferred to Eastern Germany by October 1946, but this refugee influx was offset by emigration, resulting in a net decline in the population after 1948, and in an imbalance of the sexes even more marked than that of Western Germany.<sup>35</sup>

21. Quite massive movements also occurred elsewhere. Boundary changes led to the transfer in 1945 and 1946 of about 50,000 Lithuanians, 30,000 Byelorussians and 420,000 Ukrainians from the new Poland, and 1.5 million Poles and Jews into that country. In addition, between 1945 and 1948 at least half a million Poles returned to Poland from the Soviet Union, and in 1946-1948 a further 1.5 million were repatriated from elsewhere, mostly from Germany.<sup>36</sup>

22. Other substantial movements in Central, Eastern and Southern Europe included the transfer of 100,000 persons from Czechoslovakia to Hungary, the repatriation of about 100,000 persons from Germany and the Soviet Union to Czechoslovakia, the repatriation of about 130,000 Hungarian displaced persons, and in 1950 and 1951 the expulsion of 150,000 persons from Bulgaria and their resettlement in Turkey, mainly on land abandoned by the Greeks between 1922 and 1928.<sup>37</sup>

23. The countries most affected by these post-war transfers were Poland, Czechoslovakia and Germany. As a result of both war casualties and transfers of population and land, Poland and Czechoslovakia lost population, much of it highly skilled; this hampered reconstruction after the war. By contrast, the mass transfer of German expellees into Germany at first created acute problems of labour surpluses at a time when there was little capital to stimulate investment. However, by 1950, the unemployment rate among expellees in Western Germany had fallen below 7 per cent, and more than one million expellees were employed in such vital industries as metallurgy, engineering, manufacturing and construction. Thus, despite initial hardship, the influx of expellees gave the country the work force essential for economic reconstruction.<sup>38</sup>

<sup>33</sup> See Schechtman, *Post-war Population Transfers* ... (1962).

24. Between mid-1947 and the end of 1951, the International Refugee Organization also resettled over one million displaced persons, of whom 720,000 originated from Western Germany, 145,000 from Austria, and small numbers from other countries of Europe and the Middle and Far East. The main areas of resettlement were the United States (330,000), Australia (180,000), Israel (130,000), Canada (120,000) and the United Kingdom (85,000), with smaller numbers going to France, Argentina, Brazil and other countries.<sup>39</sup> This displaced person resettlement was undertaken for humanitarian reasons at a time when there was still considerable skepticism in some of the traditional receiving countries concerning the absorptive capacities of their economies. The Australian Government, for example, began with a cautious target of only 12,000 displaced persons a year, but the numbers were increased as the economy proved hungry for new workers.<sup>40</sup> In Canada, too, and to a smaller extent in the Latin American countries, the displaced persons prepared the way for larger flows of non-refugee immigrants.

#### (c) Post-war emigration from Europe<sup>41</sup>

25. From 1946 until 1964 there appears to have been an average annual gross outflow from Europe to overseas countries of close to 600,000 persons. The main sending countries were as follows:

*Gross overseas  
emigration,  
1946-1964  
(in thousands)*

United Kingdom .....	2,648
Italy .....	1,851
Federal Republic of Germany .....	1,683
Netherlands .....	785
Spain .....	815
Portugal .....	498

26. These figures can be taken only as approximations of gross movements overseas, since the statistics are subject to many shortcomings.<sup>42</sup> Moreover, it is important to note that some of the main sending countries were at the same time major receiving countries both from overseas and from intracontinental movements. So far as overseas migration alone is concerned, the greatest loss seems to have been sustained by Italy, which received back about one fourth of the gross overseas outflow, leaving a net loss of about 1.4 million. Statistics for the United Kingdom show an inflow from overseas of about 1.4 million

between 1946 and 1964, more than half the gross outflow, which still, however, left a net loss of about 1.2 million. Owing to a large movement from Netherlands territories overseas and from Indonesia, gross immigration to the Netherlands from non-European countries during this period amounted to 87 per cent of the gross overseas outflow. Estimated return movements were also considerable in the case of some of the other countries. So far as overseas movements are concerned, the inflows have tended to rise since about 1958, while the outflows from major sending countries declined.

#### (d) The overseas receiving countries of European emigrants<sup>43</sup>

27. The main overseas receiving countries for European emigrants since the Second World War have been the United States, Canada, Australia, New Zealand, South Africa, Israel and some of the countries of Latin America. The United States has retained its role as the leading immigrant country, receiving between 1946 and 1964 approximately 4.7 million immigrants, of whom some 2.4 million were from Europe and most of the remainder from other countries of the Americas. Immigrants to the United States from Latin America, who had numbered about 60,000 annually during the 1950s, numbered more than 100,000 per year in the 1960s and surpassed in number immigrants coming from Europe.<sup>44</sup> Emigration of aliens amounted to about 25,000 annually in the post-war period until reporting was discontinued in the late 1950s.<sup>45</sup> Thus, the loss through emigration was apparently slight, but substantial as the net inflow has been, it constitutes a small fraction of the average annual increase of about 2.8 million in the United States population during this period. Changes in immigration legislation enacted in 1965 are discussed in section B.

28. Canada received about 2,350,000 immigrants between 1946 and 1964, 85 per cent of them from Europe; the principal sending countries from Europe were the United Kingdom, Italy, the Federal Republic of Germany and the Netherlands. As Canada does not maintain statistics of emigrants, figures for net migration are difficult to determine, but it has been estimated that emigration to Europe did not exceed 150,000 (or about 10 per cent of the gross inflow) between 1946 and 1957, while emigration to the United States was larger in volume.<sup>46</sup> As seen in section B, new immigration regulations adopted in 1962 made sweeping changes in regard to unsponsored

<sup>39</sup> International Labour Office, *International Migration* ... (1959), pp. 50-51.

<sup>40</sup> Holborn, *The International Refugee Organization* ... (1956), pp. 394-396. See also Appleyard, "The economics of immigration into Australia" (1967).

<sup>41</sup> Data presented in this section were taken from International Labour Office, *International Migration* ... (1959); national statistical sources; and from the files of the Statistical Office of the United Nations.

<sup>42</sup> For example, statistics for the United Kingdom before 1964 refer only to persons departing for a year or more by long sea routes. In 1964 an International Passenger Survey, which included air travel, gave a figure for overseas emigration which was almost double the 1963 figure.

<sup>43</sup> Unless otherwise indicated, sources for data presented in this section are: International Labour Office, *International Migration* ... (1959); national statistical publications; and the files of the Statistical Office of the United Nations.

<sup>44</sup> United States, Bureau of the Census, *Statistical Abstract of the United States, 1967* (1967), p. 96.

<sup>45</sup> Akers, "Immigration data and national population ..." (1967), p. 267.

<sup>46</sup> International Labour Office, *International Migration* ... (1959), pp. 152-153, 191-192. Gross emigration to all areas was estimated at over 400,000 for the period 1946-1954. Timlin, "Canada" (1958), p. 150. For the 1951-1961 intercensal period, it has been calculated that about 400,000 foreign-born persons emigrated, compared with an immigration of 1.5 million. Pankhurst, "Migration between Canada ..." (1966), p. 56.

immigrants, setting requirements only as to skill or training. The basic objective of the new regulations was to remove any suggestion of discrimination on grounds of race or citizenship and to ensure that the new immigrants should have the skills required by the Canadian economy.<sup>47</sup> The proportion of all immigrants coming from Europe had already dropped to less than three-quarters in the early 1960s before the new legislation went into effect, and it showed little change in the next few years. On the other hand, there was a noticeable rise in 1964 and 1965 in the proportion of immigrants from Asia; about 4 per cent were from Asia in 1960-1963, 6 per cent in 1964, and 8 per cent in 1965.

29. Until 1966, Australian policy restricted immigration for permanent settlement almost wholly to Europeans; but within the European flow, there have been marked changes in the post-war period, as compared with pre-war patterns, partly as a result of changes in the provisions for State-assisted immigration (see section B.2 below). About half of the total of slightly more than two million persons arriving in Australia between October 1945 and March 1964, and intending to stay for twelve months or more, received passage assistance; of those receiving assistance, about half were non-British. The Italians, numbering about 272,000, dominated the non-British flow, other important groups being the Dutch (135,000), Greeks (112,000) and Germans (98,000).<sup>48</sup> Over the period from January 1945 to the end of 1964 there were more than 700,000 "long-term and permanent departures", compared to 2.2 million arrivals in the same category, thus leaving a net immigration of about 1.5 million.

30. British immigrants have dominated the post-war intake of both New Zealand and South Africa. New Zealand, with a net gain from migration of 246,000 between April 1946 and March 1965, has placed less emphasis than Australia on recruitment and sponsorship, and the only substantial supply of immigrants coming from countries other than the United Kingdom and Australia has come from the Netherlands. From 1946 to 1964, about 58 per cent of the total number of European immigrants to South Africa came from the United Kingdom, the other main European contributions coming from the Netherlands and the Federal Republic of Germany. A feature of South African international migration during the post-war period has been a two-way movement between South Africa and Rhodesia, the net movement varying in accordance with political conditions in the two countries. Migration trends in South Africa are more fully discussed in section A.3 below.

31. Israel, with three fifths of its Jewish population foreign-born at the end of 1964, is the classic example in the contemporary world of an immigrant country. The greatest movement into Israel occurred between 1948 and 1951, the period of the "ingathering of the exiles", when 690,000 Jewish persons, about half of them from Europe (340,000), but sizable numbers also from

Asia (240,000) and Africa (90,000), moved into the country. Of the number coming from Europe, more than two thirds were from Poland and Romania. From the date of the country's independence in May 1948, through to the end of 1964, total immigration had reached about 1.2 million. As discussed in section A.2, very large numbers of Palestinian Arabs left Israel after the founding of that State. The circumstances of Israel were unique in recent migrations, in that the building of a new nation rather than the growth of an established country was involved.

32. The records of European emigrant countries indicate a net migration of over one million persons from Europe to Latin America between 1950 and 1964; since the mid-1950s the annual figures have been declining, and the net gain became negligible before the end of the period. Return migration was apparently high, amounting perhaps to one-third of the gross immigration.<sup>49</sup> All but a small number of European immigrants to Latin America came from three countries of Southern Europe: Italy, Portugal and Spain. By the early 1960s more Italian migrants were returning to Italy from Latin America than were emigrating there. While Spain continued to show a loss, on balance, of migrants to Latin America, the number of Spaniards emigrating to other European countries was about four times the number going to Latin America in 1960-1963.<sup>50</sup> Owing to the high rate of natural increase, immigration has not been numerically important as a supplement to population growth in most countries of Latin America in the post-war period. The principal receiving countries have been Argentina, Brazil and Venezuela, but in relation to population size, the volume of immigration has been important only in Venezuela and, to a lesser extent, in Argentina.<sup>51</sup> Uruguay received a sizable number of European immigrants in relation to her population size, but outflows to other countries, particularly Argentina, appear to be partly unrecorded.<sup>52</sup> Small-scale selective immigration is highly desired by Latin American countries in order to supply necessary skills. Unfortunately, these countries have become in recent years less attractive economically to possible European emigrants, owing to the more rapidly rising standards of living in other immigrant countries and in Europe itself.<sup>53</sup>

#### (e) Immigration into European countries

33. In France, immigration had already begun to exceed emigration by the 1870s, and after 1920 the gaps left by casualties in the First World War were filled by a massive immigration primarily of Italians, Poles and

<sup>47</sup> Fairclough, "Social implications of the new ..." (1962), pp. 61-62.

<sup>48</sup> For a detailed study of Southern European settlement in Australia, see Price, *Southern Europeans in Australia* (1963).

<sup>49</sup> These estimates differ somewhat from the statistics of the countries of immigration, which are believed to be less reliable. For data derived from the latter source, see, for example, International Labour Office, *International Migration* ... (1959), pp. 193-198; Pan American Union, *Immigration in Latin America* (1964), p. 10. See also Neiva, "International migrations ..." (1965), p. 128.

<sup>52</sup> United Nations, *World Population Prospects* ... (1966), p. 114.

<sup>53</sup> Neiva, "International migrations ..." (1965), p. 128.

Spaniards, but also including Algerians, Tunisians and Moroccans, residents of French colonies being able to enter France without restriction.<sup>54</sup> Net immigration averaged about 200,000 persons annually from 1921 to 1931, but showed a negative balance during the depression.<sup>55</sup> The inflow was resumed on a large scale after the Second World War, the intake of permanent immigrant workers and their families from 1946 to 1964 being about one and a half million.<sup>56</sup> The Italians were preponderant in the earlier years of this period,<sup>57</sup> but in the early 1960s Spain and later Portugal supplanted Italy as the main source of migrants, with Morocco becoming an important source by 1963-1964.<sup>58</sup> In addition, there has been a sizable two-way movement between Algeria and France of Algerian Moslems, many of them workers, during this period, with a net balance in France's favour.<sup>59</sup>

34. While France had more than one million of the total of over 3 million foreign workers from Europe and other continents estimated to have been employed in continental Western European countries in 1964,<sup>60</sup> in recent years the Federal Republic of Germany and Switzerland have had an even stronger attraction for migrants. Switzerland has absorbed a steady inflow of foreign labour since the Second World War, as a result of rapid economic expansion and the slow growth of the indigenous labour force. This inflow is to some extent seasonal, the summer figures being much higher than the winter figures. In February 1964 there were over half a million foreign workers registered in Switzerland, compared with an average of only about 100,000 in February of the years 1949-1951. Foreign workers constituted almost a quarter of the total labour force of Switzerland in 1964—a much higher proportion than in any of the other European countries of immigration.<sup>61</sup> Over a quarter of these workers were employed in construction, and about one fifth in the metals and machinery industry in 1964. Italians made up about two thirds of the total foreign labour force at that time.<sup>62</sup>

35. The Federal Republic of Germany, which showed a substantial net loss on overseas movements during the years following the war, recouped this loss through immigration received from other European countries. In addition to the 9.4 million refugees who had entered the country by September 1950, and the continued inflow from Eastern Germany and the former east German provin-

ces,<sup>63</sup> in the 1960s there was a very large immigration of foreign workers, mainly from Italy, Greece, Spain, Turkey and Yugoslavia.<sup>64</sup> In September 1964 there were about one million foreign workers in the Federal Republic of Germany, compared to only about 130,000 in the middle of 1958. Nearly one third of these workers in 1964 were Italians.<sup>65</sup>

36. Belgium and Sweden have also received a sizable immigration during the post-war period, the latter mainly from other Scandinavian countries.<sup>66</sup> Although both government and private sources in the Netherlands had deliberately assisted and encouraged emigration overseas after 1945,<sup>67</sup> the total gross outflow to overseas as well as Continental destinations from 1946 to 1964 of more than a million was almost entirely offset by a return from Netherlands overseas territories and Indonesia of about half a million, and by an inflow of another half-million from all other sources.<sup>68</sup>

37. Since the Second World War the United Kingdom has received substantial numbers of immigrants both from continental Europe and from overseas.<sup>69</sup> Between 1946 and 1957 nearly half a million continental Europeans, most of them workers, were admitted to the United Kingdom, and the net recorded balance of immigration from the Republic of Ireland was 318,000.<sup>70</sup> Between the mid-1950s and 1962 there was a flood of non-European immigration into the United Kingdom from the West Indies, particularly Jamaica, from India and Pakistan and, to a much smaller extent, from West Africa.<sup>71</sup> This flow was stemmed (but not stopped) by the Commonwealth Immigrants Act of 1962 (see section B.2 below). Nevertheless, by September 1964 there were estimated to be 800,000 immigrants from the new Commonwealth countries (i.e., excluding Australia, Canada and New

<sup>63</sup> Wander, "Migration and the German economy" (1958).

SOURCE: Compiled from data in United Nations, *Demographic Yearbook*, 1965 ... (1966); ..., 1966 ... (1967); ..., 1967 ... (1968).

<sup>a</sup> Net migration has been calculated by subtracting natural increase (i.e., the excess of births over deaths) from the total population increase during the period.

<sup>b</sup> Unofficial estimate since official 1960 estimate was not revised for 1961 census results.

<sup>c</sup> Figures relate to December 1950 and December 1960 census dates and changes between these dates.

<sup>d</sup> For midyear 1951. Official estimate for midyear 1950 is out of line with 1961 census result.

<sup>e</sup> Excluding countries with less than 200,000 population in 1960.

Zealand) in the United Kingdom.<sup>72</sup> Despite the poor quality of existing migration data for the United Kingdom, which makes precise assessment impossible, it appears that there was a reversal of the traditional migratory flows and that in the latter 1950s, the United Kingdom became a country of net immigration.<sup>73</sup>

38. In view of the shortcomings of migration statistics, the net effect of migratory movements in European countries may be calculated more accurately by comparing the total population at or around two census dates and the balance of births and deaths between these dates. Derived in this manner, the net product of all movements, overseas as well as intracontinental for the 1950-1960 decade, is shown for the major countries of Europe in table VII.1 above.

39. As seen in this table, there was heavy net out-migration from both Eastern and Southern Europe, while Western Europe showed a net gain of 3.9 million. The net loss to Europe as a whole through emigration amounted to 2.6 million between 1950 and 1960. In contrast, Europe in the 1960s became a continent of net immigration. This reversal, which occurred despite continued out-migration to North America and Oceania, was made possible by the repatriation of close to one million Europeans from former overseas colonies during 1960-1966, and by the already mentioned substantial intake of workers from Asia, North Africa and the West Indies. Two countries which had experienced net emigration in the 1950s—the Netherlands and the United Kingdom—recorded net gains through migration in the 1960s.<sup>74</sup> Prosperous economic conditions and a shortage of labour in industrialized countries of Western Europe in the 1960s also drew many intra-European migrants, mainly from the countries of Southern Europe. Migrants have been attracted to a widening geographical area within Europe, and the movements across international boundaries have been accompanied by internal flows toward the centres of industrial development.<sup>75</sup> The countries of Western Europe have been successful in competing with some of the traditional overseas receiving countries for migrants from Southern Europe. This emigrant market may now be diminishing, and it is likely that in the future, as in the recent past, net migration will be the product of complicated intra-European and overseas flows.<sup>76</sup>

## 2. INTERNATIONAL MIGRATIONS OF ASIANS

40. Within Asia during the last one hundred years the principal countries of immigration have included Manchuria and certain countries of South and South-East Asia. The immigrants have come mainly from China, India and Japan, and to a smaller extent from Korea.<sup>77</sup> The Chinese are to be found in all countries of South-East Asia,<sup>78</sup> while the Indians are in considerable numbers in Burma, Ceylon and Malaysia, where they were drawn primarily by the demand for plantation labour during the latter part of the nineteenth and early twentieth centuries.<sup>79</sup>

41. The total number of Asians living outside their own countries before the Second World War has been estimated at between 10 and 20 million.<sup>80</sup> The Chinese and Indian migrant communities are now for the most part settled in their countries of adoption. With restrictions on the recruitment of unskilled labour in the emigrant countries and on new immigration in the receiving countries (see section B.2), all of which have rapidly growing populations, the amount of migration in the post-war period, apart from refugee population transfers and post-war repatriation of Japanese and Koreans, has been small.<sup>81</sup>

42. By far the largest post-war Asian civilian population transfer occurred between India and Pakistan following partition. In 1951, there were about 7.2 million refugees in Pakistan and a similar number in India. Although the numbers involved in these movements were the same on both sides, the geographical distribution of population in each country was to some extent altered. In West Bengal in India the incoming Hindus were three or four times the number of emigrating Moslems. On the other hand, immigrants to the Punjab in India fell far short of compensating for the number of Moslems who left. In relation to total population, the concentrations of refugees were greatest in Karachi Federal District in Pakistan and in Delhi state in India. According to available

<sup>77</sup> United Nations, "International migrations in the Far East ..." (1951), pp. 14-15.

<sup>78</sup> Estimates of their number vary. See, for example, Purcell, *The Chinese in Southeast Asia* (1965), p. 3; Hayase, "Overseas Chinese in southeast Asia" (1965), p. 580.

<sup>79</sup> Indian migrants were mostly labourers on rubber and tin estates in Malaya, and on coffee and tea estates in Ceylon, though there was also a small migration of traders and money-lenders. Sundaram, "Effects of emigration ..." (1955), p. 230. See also Kondapi, *Indians Overseas ...* (1951), pp. 29-52; Mukerjee, *Le migrazioni asiatiche ...* (1936); Davis, *The Population of India and Pakistan* (1951), pp. 99-106; Pillai, *Labour in Southeast Asia ...* (1947), pp. 73-75, 123-130, 143-144; Jacoby, *Agrarian Unrest in Southeast Asia* (1961), pp. 9, 90-92; Silcock, "Migration problems of the Far East" (1958), p. 262.

<sup>80</sup> United Nations, *Report of the Secretary-General on the Allocation of Functions ...* (1948), p. 90. The figures refer to "nationals" and thus probably include some persons born in the country to which their parents or grandparents had migrated. For studies of Japanese emigration, see Ishii, *Population Pressure ...* (1937), pp. 188-206; Ichihashi, "International migration of the Japanese" (1931). For summaries of Korean emigration, see Taeuber and Barclay, "Korea and the Koreans ..." (1950); Population Index, "Korea in transition ..." (1944), pp. 233-234.

<sup>81</sup> United Nations, "International migrations in the Far East ..." (1951).

official statistics, between 1951 and 1956, about 1.5 million Hindus moved from Pakistan into eastern India, 500,000 Moslems from west Bengal into east Bengal in Pakistan, and a further 650,000 from India into West Pakistan. These movements affected mainly the partitioned States of Bengal and the Punjab.<sup>82</sup>

43. Another significant population shift arising from the war and its immediate aftermath was the transfer of over 5 million civilian and military Japanese back to Japan by the end of 1946; by 1956, the figures had risen to 6.3 million. These repatriates greatly exceeded in number the 1.2 million foreigners who departed from Japan between 1945 and 1950. Net immigration from these movements amounted to about 5 million, which was about half the increase in Japan's population between 1945 and 1950.<sup>83</sup>

44. An important refugee transfer arose from the partition of Palestine in 1947. At the end of 1948, all but about 110,000 of 860,000 Palestinian Arabs had left the present boundaries of Israel for surrounding territories, particularly Jordan, the Gaza area, Lebanon and Syria. Some of these subsequently moved back into Israel, but the majority remained to become the core of the 960,000 refugees who were in the care of the United Nations Relief and Works Agency for Palestine Refugees in the Near East by 1950.<sup>84</sup> By the middle of 1965, the number of refugees registered with the Agency had risen to 1,280,823, about half of whom were under eighteen years of age.<sup>85</sup>

45. A major Asian immigration, when considered in relation to the population size of the receiving country, has been from China to Hong Kong. According to the 1961 census of Hong Kong, about 1.6 million persons, or over half of the population of 3.1 million, were born outside Hong Kong. About half of the immigrants were estimated to have arrived before September 1949.<sup>86</sup> Kuwait is another country where immigrants constitute a large proportion of the total population.<sup>87</sup>

46. In the post-war period, which has seen the establishment of many independent States in Asia, barriers have been raised against immigration in some countries, and earlier immigrants have in some cases been repatriated. Almost 100,000 Chinese were repatriated from Indonesia in 1961.<sup>88</sup> Indian migration into Ceylon and

Burma has been restricted, and both Indian and Chinese migrations have virtually ceased in Malaysia.<sup>89</sup>

47. The migration of Asians to other continents has been on a relatively small scale in modern times, largely because of restrictions imposed by potential receiving countries. Nevertheless, the political and social significance of such movements as did occur has been considerable. One of the important movements from Asia between the middle of the nineteenth century and the First World War, was of recruited and indentured labour.<sup>90</sup> The resulting Asian communities (mainly of Indian origin) in countries such as Fiji, Mauritius, Trinidad and Tobago and Guyana are either locally in the majority or form substantial minorities.<sup>91</sup> Originally recruited to work as indentured labourers in South Africa, many Indians remained after the completion of their indenture to become small farmers and merchants.<sup>92</sup> There was also a migration of Indian labourers, artisans, clerks and small traders to East Africa.<sup>93</sup> There have been modest movements of Japanese migrants to the United States, beginning late in the nineteenth century, and to Brazil in the twentieth century.<sup>94</sup> About 20,000 Japanese migrated to Brazil during 1946-1957, and over 30,000, most of them spouses or children of United States citizens, migrated to the United States.<sup>95</sup> Numerically, the largest migration from Asia to other continents during the post-war period was that from India and Pakistan to the United Kingdom.<sup>96</sup> Qualitatively, the most important post-war Asian migration has been the outflow of indigenous, professionally trained personnel and other skilled manpower, which has been parallel, but in the reverse direction, to the movement of technical assistance experts and other highly qualified persons from the richer countries of Europe and America.

### 3. INTERNATIONAL MIGRATION IN AFRICA

48. Since the abolition of the slave trade in the nineteenth century, few Africans have left the continent for permanent residence abroad. Intracontinental migration has been a much more common phenomenon, following the acquisition of territories by European Governments and the introduction of a market economy requiring wage labour. The labour requirements of European agricultural, mining and industrial enterprises in Africa often

<sup>82</sup> International Labour Office, *International Migration* . . . (1959), pp. 108-120. A different assessment of recent migration balances between India and Pakistan has been arrived at by Visaria. Working with census data for the two countries, he estimated a net immigration of 1.32 million into India from Pakistan during the 1951-1961 intercensal period. Visaria, "Mortality and fertility in India, 1951-1961" (1969), p. 113.

<sup>95</sup> International Labour Office, *International Migration* . . . (1959), pp. 206-207.

<sup>96</sup> Data from the British Home Office show that between 1955 and midyear 1962 there was a net immigration of close to 145,000 persons from India and Pakistan. Davison, *Black British* . . . (1966), p. 3.

could not be met on a local basis or even within the country concerned.<sup>97</sup> Moreover, native farmers, particularly in West Africa, have also employed migrant labourers from other countries on a large scale to assist in the seasonal peak periods of agricultural work.<sup>98</sup> This intra-continental movement has tended to be primarily one of male workers moving temporarily out of tribal areas for employment, with periodic return movements to tribal homes, although in recent years there is evidence of more extensive family emigration, particularly in West Africa.<sup>99</sup> Statistical data are too meagre to measure with any degree of accuracy the flows of international migrations within Africa. It has been said that, as a conservative estimate, at least five million people are involved each year in migrant labour movements in Africa south of the Sahara.<sup>100</sup> Not all of these movements, of course, involve the crossing of international boundaries.

49. While some migrations have been of the traditional type of nomadic pastoralists, they have been increasingly the consequence of three factors: the poor land resources available to African tribes, the accelerating rate of population growth, and the attraction of wage labour in areas of relatively rapid economic growth. Recruitment of wage labour encouraged the temporary migration of male workers, but as wages were too low to allow these workers to transplant their families to their places of employment, they tended to return frequently to their tribal areas. African society, therefore, came to depend largely upon two types of economic activity: subsistence agriculture at the base, and industrial employment outside the base as a means of increasing cash income. The complement of this situation was that employers came to rely upon an apparently inexhaustible supply of unskilled labour to supplement the European capital, *entrepreneurs* and skilled manpower that were associated with European immigration.<sup>101</sup>

50. The directions of migration are known with greater certainty than the numbers involved.<sup>102</sup> In Central and Eastern Africa, the main movements have been towards the south. The two chief immigrant areas for labour have been the Republic of South Africa and Rhodesia. The 1960 census of South Africa enumerated about 580,000 Africans who had been born in other countries, mainly Lesotho (Basutoland), 197,000; Mozambique, 161,000; the former Federation of Rhodesia and Nyasa-

land, 96,000 (two thirds of these were from Malawi); Botswana (Bechuanaland), 59,000; and Swaziland, 39,000.<sup>103</sup> The large number of persons from Lesotho (Basutoland) present in South Africa is one of the striking features of interterritorial migration in this region. Nearly one fifth of the population of Basutoland was reported to be absent from the country at the 1956 census, the majority of the absentees having migrated to work in South African mines.<sup>104</sup> Country-of-birth data for Rhodesia in 1962 show that there were 200,000 Africans from Malawi, 118,000 from Angola and Mozambique, and about 70,000 from Zambia.<sup>105</sup> In 1963, Zambia had about 65,000 Africans from Malawi, about 60,000 from Angola and over 50,000 from Rhodesia.<sup>106</sup> Migration patterns in Eastern, Central and Southern Africa are more complicated than in the West. For example, Tanzania and Uganda have taken immigrants from Burundi and Rwanda, but they have also lost workers elsewhere.<sup>107</sup> Cotton-growing areas of Buganda in Uganda, farms in the highlands of Kenya, sisal estates in Tanzania, the copperbelt in Katanga (the Democratic Republic of the Congo) and Zambia, and the gold mines of the Witwatersrand in South Africa have been the chief centres attracting migrants from poorer areas.<sup>108</sup> Organized schemes of labour recruitment have played an important role in drawing workers to South Africa, but the success of these schemes has been affected by the South African Government's policy of *apartheid* (see also section B.2 below).

51. In Western Africa the movement of Africans has been to the south and west, particularly into Ghana where mining and agriculture are largely dependent upon extra-territorial labour. The number of foreigners entering Ghana temporarily or permanently rose from 108,000 in 1938 to 392,000 in 1953.<sup>109</sup> The census of Ghana in 1960 showed that one in twelve of the population was foreign-born and more than one in eight was of foreign ancestry. The most important sources of the foreign workers have been Togo, Upper Volta and Nigeria. This immigration has concentrated more and more in urban areas; almost one third of males aged 25-44 years in Accra in 1960 were foreign-born.<sup>110</sup> While migrants have more frequently been accompanied by their families in recent years, it is estimated that only about one fifth brought relatives with them in the first instance.<sup>111</sup>

<sup>97</sup> For example, see Hailey, *An African Survey ...* (1957), pp. 1270-1271.

<sup>98</sup> In West Africa, African farmers used hired labour from early in the century. Berg, "The economics of the migrant labor system" (1965), pp. 163, 174. This practice is also common in Uganda. See Southall, "Population movements in East Africa" (1961), pp. 177-178.

<sup>99</sup> Oblath, "International migrations in Africa ..." (1963), p. 8. With respect to Ghana, see Caldwell, "Migration and urbanization" (1967), pp. 113-121. This has also been noted with reference to migration into South Africa. Hailey, *An African Survey ...* (1957), p. 1431.

<sup>108</sup> Prothero, *Migrants and Malaria* (1965), p. 44; Smith and Blacker, *Population Characteristics ...* (1963), pp. 27-30. See also Mitchell, "Wage labour and African population ..." (1961).

<sup>109</sup> International Labour Office, "Inter-territorial migrations ..." (1957), p. 306.

<sup>110</sup> Caldwell, "Population: general characteristics" (1967), pp. 25-27.

<sup>111</sup> Caldwell, "Migration and urbanization" (1967), pp. 117-118.

52. Political upheavals in Africa have also added considerably to the international movements of Africans. The disturbances preceding Algerian independence brought about a sizable exodus of Algerians who sought refuge in neighbouring Tunisia and Morocco; over 180,000 of these refugees were repatriated in May-July 1962.<sup>112</sup> In March 1964, there were 153,000 refugees from Rwanda in Burundi, the Democratic Republic of the Congo, Tanzania and Uganda, and about the same number of refugees from Angola were found in the Democratic Republic of the Congo.<sup>113</sup> Other movements on a smaller scale have occurred among some West African countries following their attainment of independence.<sup>114</sup>

53. The general pattern of the international migration of Africans during this century is thus one of very considerable movements, to be numbered in millions of persons,<sup>115</sup> across political boundaries which may bear little relation to ethnic or cultural zones.<sup>116</sup> The system of African migration has provided an important safety valve against the pressure of population on scarce resources. However, certain social ills, such as the disruption of family life resulting from detribalization, and extremely low wages, are often associated with it.<sup>117</sup> Moreover, the system sometimes led to a pattern in which a majority of the able-bodied men might be away for a substantial part of their adult life, a situation which some analysts believe contributed to economic and social stagnation in the home communities.<sup>118</sup> The establishment of new States, opposition to policies which associate migration with segregation and restrictions upon economic and social rights, and the emphasis upon economic development plans within each new nation are tending to restrict movements across national boundaries (see section B.2 below) and to accentuate internal movements from rural to urban areas, a trend particularly apparent in the Rhodesian copper belt and in the coastal towns of Ghana.

54. So far as intercontinental migration is concerned, the most important movement involving Africa from the middle of the nineteenth to the middle of the twentieth century was the immigration of European settlers.<sup>119</sup> From an estimated population of 135,000 in 1835,<sup>120</sup> the European population in Africa had increased to approximately 6 million by 1960; about 3 million were in the Republic of South Africa, over 1.5 million in

North Africa, and over 200,000 in Rhodesia.<sup>121</sup> Kenya, Tanzania, Uganda and Zambia have received immigrants chiefly from Great Britain,<sup>122</sup> but the number of Europeans settled in these countries is small in comparison with the countries mentioned earlier.

55. In South Africa the white population at the 1960 census consisted of 1.8 million persons whose home language (that is, the language spoken most commonly at home) was Afrikaans and 1.2 million whose home language was English. The Afrikaners are for the most part descended from a small number of early settlers, mostly Dutch and German. British immigration on a large scale took place in the late nineteenth and early twentieth centuries. Following the Anglo-Boer War there was a brief spurt in immigration, which then subsided owing to a period of economic depression. Immigration picked up again during the prosperous 1920s, when many persons arrived from Germany and the Netherlands, as well as from such Eastern European countries as Lithuania, Poland and Latvia. The Quota Act passed in 1930 severely restricted immigration from Eastern Europe however. Immigration declined to a very low level, and was exceeded by emigration during the war years. Between 1946 and 1964 over 250,000 immigrants from Europe entered South Africa, nearly three fifths of them from the United Kingdom. In 1961, new measures to recruit settlers were followed by a sharp upward trend in immigration, and the Government's goal of attracting 30,000 white immigrants annually was surpassed by 1963. The appeal for new immigrants was answered, not so much by migrants coming directly from Europe, as by white migrants from other parts of Africa; in 1961-1963 over half of the white immigrants to South Africa came from the African continent, mostly from the Rhodesias and Kenya as a result of political uncertainties in those countries. On the other hand, emigration to the Rhodesias, which had accounted for a large proportion of all emigration from South Africa, fell off considerably after 1957.<sup>123</sup>

56. The immediate post-war years also saw sizable movements of migrants from the United Kingdom into the Rhodesias, and of Europeans into other African territories, for example Portuguese into Angola and Mozambique, Belgians into the Congo, and French into the territories of French West Africa,<sup>124</sup> but Europeans later left in large numbers after some of these areas had achieved independence. Probably over one million

<sup>120</sup> Kuczynski, *Population Movements* (1936), p. 91.

<sup>121</sup> Data compiled from the United Nations, *Demographic Yearbook*, 1963 ... (1964); and ———, *Demographic Yearbook*, 1964 ... (1965). The estimate of 6 million includes over a million Europeans living in Algeria at the time of the 1960 population census, but this figure was greatly reduced after independence.

<sup>122</sup> Kuczynski, *Demographic Survey of the British Colonial Empire*, vol. 2 ... (1949), p. 103; International Labour Office, *International Migration* ... (1959), p. 200.

<sup>123</sup> Trends in white immigration to South Africa are discussed in Marquard, *The Peoples and Policies* ... (1962); Robertson, "South Africa" (1958); and Katzen, "South-African immigration ..." (1963). Statistics for recent years are from South Africa, Bureau of Statistics, *Statistics of Immigrants* ... (1965). See also United Nations, *Demographic Yearbook*, 1963 ... (1964), table 10.

<sup>124</sup> International Labour Office, *International Migration* ... (1959), pp. 198-200.

Europeans left North Africa. It is estimated that only about 110,000 Europeans out of about one million remained in Algeria after that country attained independence.<sup>125</sup> In the United Arab Republic also, many nationals of European countries left after the Suez crisis in 1956.<sup>126</sup>

57. In addition to those who came as indentured labourers, there was a sizable unassisted migration of Indians to East Africa,<sup>127</sup> as mentioned in section A.2 above. In the East African countries of Kenya, Tanzania and Uganda, Indians constitute the largest non-native population group, outnumbering the Europeans in a ratio of about 4.5 to 1 in 1964.<sup>128</sup>

## B. Factors affecting international migration

### 1. ECONOMIC, SOCIAL AND OTHER FACTORS

58. Most analyses of the factors affecting migratory movements have been concerned with the relation between the volume of migration and economic, social, political and other conditions prevailing in the areas of immigration and emigration. They have thus been aimed at identifying the circumstances which make certain areas attractive to migrants and those which cause other areas to experience out-migration. Inquiries into individual motivations for migration have been fewer, and it has been pointed out that migrants are often themselves unaware of their real motives for migrating.<sup>129</sup> Recently, some writers have stressed the need for examining the migration process as a whole in order to illuminate the complex interactions of economic, social, cultural and psychological factors which have often provided the motivating forces in migrations.<sup>130</sup>

59. A few recent surveys carried out by sociologists and social psychologists have attempted to evaluate the importance of various factors in shaping individuals' decisions to migrate. Thus, an inquiry among Dutch emigrants in the mid-1950s suggested that while economic motives were frequently present, they could not be considered predominant, and that social and psychological factors also played a major role.<sup>131</sup> Other studies

identified the following among the factors which influenced migratory behaviour: degree of attachment to cultural patterns in the home country, previous residence abroad, presence of relatives in the country of destination, and a general feeling of discontent.<sup>132</sup> Certain personality traits associated with a high propensity to migrate were also identified, among them great vitality, strong self-assertion, an active personality and individualistic attitude.<sup>133</sup> It has been pointed out that whatever the motivation of the initial emigrants from a given geographic area or kin-group, chain migration frequently continues to move other members of the group by co-operative efforts which cut across economic factors.<sup>134</sup>

60. In attempting to formulate a theoretical framework for migration, Lee summarized the factors which enter into decisions of individuals to migrate under four categories: (a) factors associated with the area of origin; (b) factors associated with the area of destination; (c) intervening obstacles; and (d) personal factors. He pointed out the subjective nature of the assessment of positive and negative factors in the areas of origin and destination on the part of prospective migrants in view of their imperfect knowledge, particularly of the area of intended migration.<sup>135</sup> While improved communications have diminished the importance of the latter factor, it is still of some consequence, particularly in the developing countries.

61. The important role that social and cultural factors have played in determining the volume and direction of migrations cannot be denied. Emotional attachments to a community, culture, language, political or social institutions, or to a way of life, have at various times deterred people from moving from their native lands, or determined the choice of their new country. Such considerations account in large part for the fact that much of the emigration from the United Kingdom has been directed to the British Commonwealth during recent decades.<sup>136</sup> In like manner, Spanish and Portuguese emigrants have been drawn to Latin America, and Irish emigrants to the United States, because of the similarity in language and traditions.<sup>137</sup> Increases in emigration

<sup>125</sup> McDonald, "The repatriation ..." (1965), p. 148.

<sup>136</sup> See, for example, figures for 1946-1957 given in International Labour Office, *International Migration ...* (1959), pp. 170-172.

<sup>137</sup> Forsyth, *The Myth of Open Spaces ...* (1942), p. 48. But cultural affinities of the immigrant with his adopted country have not always prevented a substantial return movement, for example from South America to Italy and Spain, and from Australia and Canada to the United Kingdom. For return rates from Latin America, see Bouscaren, *International Migrations since 1945* (1963), pp. 75, 87. See also Appleyard, "Determinants of return migration ..." (1962).

from Europe following international crises, such as Berlin (1949) and Suez (1956), have had essentially psychological rather than economic motivations. The desire to escape from religious, ethnic or political oppression has also been a prime motivation for certain important migrations both of modern and earlier times.

62. Analyses of factors determining the main currents of international migration in the past have generally been based on the authors' assessments of what economic, social and other conditions were of importance to the migrants. Aside from forced movements of population resulting from war, social upheavals or natural catastrophes, most migrations in modern times are considered to have had economic factors as their most important underlying motives.<sup>138</sup> Migrants strive to obtain improvements in their material conditions of life, and they are attracted to areas where economic opportunities appear to be more abundant and remuneration higher.<sup>139</sup>

63. The classical analysis of factors determining international migration currents in the past has been in terms of "push" and "pull" theories, with movements tending to flow from countries with relatively low levels of living to those with relatively high levels. Usually, both factors have been involved in migratory movements. It is now generally accepted that the great underlying factors motivating international migrations during the nineteenth century were the push of land scarcity in Europe and the pull of virgin lands, available at low cost in the New World.<sup>140</sup> The same push force operated in high-density rural areas in China, India, Korea and pre-industrial Japan. While the more sparsely populated land of Manchuria attracted a steady stream of Chinese settlers, many of the Asian emigrants went to low-paid jobs on plantations or in factories and mines of foreign countries.<sup>141</sup>

64. In America, the attraction of unoccupied land was enhanced by the development of transportation facilities and other urban and commercial influences associated with the westward movement across the continent.<sup>142</sup>

<sup>138</sup> See, for example, Thomas, "International migration" (1959), p. 528.

<sup>139</sup> Appleyard, *British Emigration to Australia* (1964), pp. 54-55; Citroen, *Les migrations internationales* ... (1948), p. 22; Sauvy, *Richesse et population* (1944), pp. 169-172; Isaac, *Economics of Migration* (1947), pp. 28-34.

<sup>140</sup> The push of impoverished agricultural workers from the land was particularly strong in Ireland. See, for example, Harkness, "Irish emigration" (1931), pp. 261-264. The scarcity of land resources as a factor in emigration from other European countries is discussed in such works as Bürgdorfer, "Migration across the frontiers ..." (1931), pp. 346-353; Obolensky-Ossinsky, "Emigration from and immigration into Russia" (1931), pp. 548-552, 578; Hansen, *The Atlantic Migration* ... (1940); Blegen, *Norwegian Migration* ... (1931), pp. 167-173; Ferenzi, "Introduction and notes" (1929), p. 83; and Klezl, "Austria" (1931), pp. 403-404. On the attractive power of land in the United States and Canada, respectively, see Penrose, *Population Theories* ... (1934), p. 178; and Mackintosh, *Prairie Settlement* ... (1934), pp. xii, 58-85.

<sup>141</sup> United Nations, "International migrations in the Far East ..." (1951); Young, "Chinese immigration ..." (1932), pp. 334-338; Sundaram, "Effects of emigration ..." (1955), vol. 2, p. 232.

<sup>142</sup> See, for example, Wiers, "International implications ..." (1949), p. 39; Hansen, *The Immigrant in American History* (1942), p. 69.

This continuous pursuit of the frontier was not duplicated in Latin America, and despite the encouragement of Governments (see section B.2), the latter region has attracted relatively few immigrants for land settlement.<sup>143</sup> In addition to obstacles such as climate and topography, health hazards and transportation difficulties, the systems of land tenure and taxation in Latin America made it relatively difficult to acquire good land at attractive prices.<sup>144</sup>

65. With the advance of industrialization in the United States, pull factors in addition to the lure of the land became an important force in migration flows. Employment opportunities were increasingly associated with non-agricultural activities, and even before the end of the nineteenth century the bulk of immigrants to the United States were being absorbed into urban areas.<sup>145</sup>

66. The growth of industrialization both in countries of emigration and immigration altered the economic basis of international migration. Pressure of population on the land and little improvement in rural productivity sustained the push to emigrate in Southern Europe, but in countries undergoing industrialization the main push factor became labour redundancy in the manufacturing sector of the economy. First in England, and later in Germany, conditions which prevailed during the early stages of industrial development, when handicraft workers were unable to compete with factory production and the introduction of labour-saving machinery frequently created immediate unemployment, impelled many workers to migrate.<sup>146</sup> Continued industrialization on a large scale, however, eventually removed the need for emigration, as the former emigrant countries became able to provide employment opportunities for their population. The volume of emigration from the industrialized countries of Northern and Western Europe declined during the latter part of the nineteenth century and the early part of the twentieth.<sup>147</sup> Great Britain received substantial immigration from Ireland,<sup>148</sup> and Germany became a principal country of intra-European immigration.<sup>149</sup>

<sup>143</sup> Davis, "Future migration into Latin America" (1947); Smith, *Brazil* ... (1963), pp. 118-120.

<sup>144</sup> The failure to integrate land settlement schemes with economic and social development plans has also been mentioned as an unfavourable factor. United Nations, Economic Commission for Latin America, *Immigration in Chile* (1950), pp. 12-20, 85-87; ———, *Immigration in Brazil* (1950), pp. 97, 107; ———, *Immigration in Venezuela* (1950), pp. 47-59.

<sup>145</sup> By 1900, two thirds of the immigrants in the United States were living in urban areas. Taeuber and Taeuber, *The Changing Population* ... (1958), p. 125.

<sup>146</sup> In Great Britain, which had taken the lead in industrialization, the initial unemployment which acted as a stimulus to emigration occurred before the middle of the nineteenth century. Snow, "Emigration from Great Britain" (1931), pp. 251-253. See also Berthoff, *British Immigrants* ... (1953), p. 31. In Germany, these changes took place after 1860. Bürgdorfer, "Migration across the frontiers ..." (1931), p. 343. See also Citroen, *Les migrations internationales* ... (1948), p. 25; and, for Norway, Skaug, *Memorandum* ... (1937), pp. 65-66.

<sup>147</sup> Citroen, *Les migrations internationales* ... (1948), pp. 25-26.

<sup>148</sup> Harkness, "Irish emigration" (1931), pp. 263-264; Jackson, *The Irish in Britain* (1963), pp. 9-11.

<sup>149</sup> Kirk, *Europe's Population* ... (1946), p. 97.

67. Annual fluctuations in emigration from Europe, which had earlier been closely related to the occurrence of famines and variations in harvests,<sup>150</sup> became increasingly influenced by phases of the business cycle. Jerome found that over the period from about 1870 to 1922, business cycles in both Europe and the United States tended to coincide, with immigration reaching peak flows when prosperity prevailed in both. In the few periods when the cycles did not coincide, migration showed a high degree of consistency with the course of economic activity in the United States. He concluded that, on the whole, the pull from countries of immigration was more important in determining the annual flow of emigrants in the latter half of the nineteenth century than was the push of European depressions, though there were some minor exceptions to this thesis.<sup>151</sup>

68. Dorothy Thomas, studying emigration from Sweden to the United States during the late nineteenth and early twentieth centuries, found that though "prosperity in America was highly important as a stimulus to emigration from Sweden, . . . cyclical upswings in Sweden were a far more powerful counter-stimulant than is generally recognized. In prosperous years, Swedish industry was able to compete successfully with the lure to America; and the latent agricultural push towards emigration became an active force only when a Swedish industrial depression occurred simultaneously with expanding or prosperous business conditions in the New World".<sup>152</sup> Examining emigration from Norway, Skaug also found that it was not the economic conditions in either the home country or abroad that were decisive, but the relation between them.<sup>153</sup> A number of other studies have tended to emphasize the importance of pull factors in migrations during the late nineteenth and early twentieth centuries.<sup>154</sup>

69. Several more recent economic studies have examined the dynamics of international migration in terms of "long swings" or secular fluctuations rather than of short-run business cycles. Brinley Thomas described four major

upswings and downswings in transatlantic migration between 1845 and 1913, with corresponding fluctuations in the export of capital from the United Kingdom to the receiving countries. He found that from the 1840s the long-run construction cycles in the United States and the United Kingdom were inverse to one another and that transatlantic migration was positively correlated with American building activity. These upswings in the long cycles in the United States were substantially financed by capital investments from the United Kingdom, which temporarily reduced domestic investment there, and thus exerted push at home as well as pull abroad. But foreign lending in turn stimulated the demand for imports from the United Kingdom, thus beginning the reverse cycle of encouraging increasing home investment. When the United States became an exporter rather than an importer of capital after the First World War, this complementary, inverse relation with the United Kingdom was finally broken.<sup>155</sup>

70. Kuznets examined the relationship between long swings in economic conditions and population growth in the United States, the latter being accounted for mainly by immigration trends, at least until after the First World War. Observing that long swings in immigration from a number of European countries resembled each other rather closely and that they followed swings in additions to *per capita* flow of goods to consumers in the United States, he attributed more importance to pull than to push factors, thus differing somewhat from Brinley Thomas.<sup>156</sup> Easterlin further examined the possible influence of push factors in determining long swings in immigration to the United States. Finding little evidence that emigration cycles in European countries were closely related to prior swings in natural increase in these countries, or that long swings in economic activity in European countries were inversely related to those in the United States, he concluded that emigration swings in the several countries responded primarily to swings in labour demand in the United States.<sup>157</sup> These findings are thus consistent with those of Jerome concerning the relative influence of push and pull factors in shorter term cyclical fluctuations (see para. 67 above).

71. As indicated above, non-economic factors have been important stimulants to migration, but neither

<sup>150</sup> The most famous example is the emigration occasioned by the failure of the potato crop in Ireland in 1845-1846. Harkness, "Irish emigration" (1931), pp. 264-265. Variations in yearly overseas emigration were closely related to harvests, in Germany until the latter part of the nineteenth century, and in Sweden during the 1860s. Mönckmeier, *Die deutsche überseeische Auswanderung* . . . (1912), p. 41; Thomas, *Social and Economic Aspects* . . . (1941), pp. 90-92, 166. See also Yamzin and Voshchinin, *Ucheniia o kolonizatsii* . . . (1926), pp. 100-101.

<sup>151</sup> Jerome, *Migration and Business Cycles* (1926), chap. 8. It was observed, for example, that in a few years immigration to the United States from Italy increased although economic conditions were improving in that country and worsening in the United States.

<sup>152</sup> Thomas, *Social and Economic Aspects* . . . (1941), pp. 166-169.

<sup>153</sup> Skaug, *Memorandum* . . . (1937), pp. 73-74. See also Blegen, *Norwegian Migration* . . . (1931), pp. 174-175.

<sup>154</sup> The relationships between economic conditions and migration were traced for Germany by Fürth in "Wirtschaftslage und . . ." (1930), and by Burgdörfer in "Migration across the frontiers . . ." (1931), p. 343; for the Scandinavian countries by Jensen in "Migration statistics of . . ." (1931), pp. 295-297; for Italy by Winsemius in *Economische aspecten* . . . (1939), pp. 105-111; for France by Bunle in "Migratory movements between France . . ." (1931), p. 213; for Argentina by Bunge and Garcia Mata in "Argentina" (1931), pp. 148-152; for Australia by Forsyth in *The Myth of Open Spaces* . . . (1942), pp. 30-33; and for the United States by Commons in *Races and Immigrants* . . . (1924), pp. 63-64.

<sup>155</sup> Thomas, *Migration and Economic Growth* . . . (1954), chaps. 7, 10 and 14. For a discussion of the relationship between capital movements and migration trends in the period following the First World War, see Thomas, *International Migration and Economic Development* . . . (1961), pp. 16-17, 33-36; and his "International movements of capital . . ." (1956). See also Isaac, *Economics of Migration* (1947), pp. 247-257; Pletnev, *Mezhdunarodnaia migratsiia* . . . (1962), pp. 158-216.

<sup>156</sup> Kuznets, "Long swings in the growth . . ." (1958). Kuznets further argued that the long swings in population and product were self-perpetuating, since the swings in population growth caused swings in population-sensitive capital formation which resulted in an inverse change in other capital formation and affected *per capita* flow of goods to consumers. For further discussion of long swings in population and economic variables and their relation to international migration, see Kuznets, *Capital in the American Economy* . . . (1961), pp. 316-360; Abramovitz, "The nature and significance of Kuznets cycles" (1961).

<sup>157</sup> Easterlin, "Influences in European overseas migration . . ." (1961). See also O'Leary and Lewis, "Secular swings . . ." (1955).

pre-war nor post-war voluntary emigrations provide evidence of permanent movements on any scale which have clearly continued to move *against* economic forces. Whatever the motive that directly determines the decision to migrate, the final step is usually taken only after some consideration of such matters as job opportunities, wage levels and social service benefits.<sup>158</sup> The best modern example of motivations which had initially little economic basis is probably Israel.<sup>159</sup> Recent movements, already referred to earlier in the present chapter, in which economic motivations seem to be most apparent are the labour movements in Africa, the flight of West Indians to the United Kingdom, and the large-scale emigration of workers from Southern to Northern and Western Europe.

72. The volume and direction of migration have been influenced by a great many other factors. For example, the increasing volume of overseas migration from the middle of the nineteenth century and afterwards was obviously related to the great improvements which took place in transportation facilities.<sup>160</sup> The increasing use of steamships reduced travel time and improved conditions for passengers. The building of a transcontinental railway in the United States, the expansion of railway and river transportation in Europe, and the opening of the Suez and Panama canals were all developments which facilitated migration.<sup>161</sup>

73. The increasing provisions for social security and other social welfare services in certain European countries have tended to deter emigration, since the worker may hesitate to relinquish these rights by moving to a foreign land.<sup>162</sup> In countries of immigration, social welfare measures may be less well developed or they may not apply to immigrants until after a specified period of residence. Some attempts have been made to establish international reciprocity in social insurance schemes and certain bilateral treaties and regional agreements, such as the convention on social security among the Scandinavian countries, have been worked out.<sup>163</sup>

74. Efforts to encourage migration have also been made by employers, transport companies, labour organizations, and other private organizations. In the United States during the nineteenth century, the transcontinental railway companies sought to expedite the settlement of lands along their rights-of-way by offering reduced transportation rates to America, by providing reception homes for immigrants, and by extending liberal credit for the purchase of land.<sup>164</sup> Towards the end of the century transatlantic shipping companies were active in organiz-

ing migration from Europe to America,<sup>165</sup> but such activities were later prohibited in most countries of emigration since they were often not in the best interests of the migrants.<sup>166</sup> The desire of employers for a cheap and ample labour supply was behind the intercontinental migrations of Chinese, Japanese and Indians during the second half of the nineteenth century and the first decades of the twentieth. Transportation and other costs were paid by the employers in return for a contract obligating the immigrant to work for a stated period of years, but this form of indentured or contract labour was later declared illegal in country after country.<sup>167</sup> Labour unions were active in Great Britain during the latter half of the nineteenth century in encouraging workers to emigrate, but these activities subsided as the economic and political position of the unions grew stronger.<sup>168</sup>

## 2. GOVERNMENT POLICIES

75. The Universal Declaration of Human Rights states that "Everyone has the right to leave any country, including his own, and to return to his country".<sup>169</sup> Comparatively few countries, however, formally recognize this right in constitutional laws or by judicial interpretation,<sup>170</sup> and the right is almost everywhere qualified by the possibility of the denial of travel documents on various grounds.<sup>171</sup> An International Labour Office study states that:

"Political and economic reasons have led all countries, including those which remain most attached to principles of economic freedom, to place strict controls on migratory movements with a view to preventing those which they consider undesirable. . . . Such restrictions . . . are concerned far less with emigration, which is generally unopposed, except in a very few cases, than with immigration, which nearly everywhere has given rise to defensive measures."<sup>172</sup>

### (a) Policies concerning emigration

76. Laws restricting emigration have not been uncommon in the past. They were widespread in Europe during the seventeenth and eighteenth centuries. Emigration was illegal in China from 1718 to 1860; in Japan it was

<sup>158</sup> It has been claimed that agents of shipping companies were responsible for much of the emigration from Bulgaria to the United States in the last two decades of the nineteenth century and the beginning of the twentieth. Danailov, *Izsledvaniya vrkhu* . . . (1931), pp. 144-145.

<sup>161</sup> Hansen, *Emigration from Continental Europe* . . . (1940), pp. 185, 195, 299-300.

<sup>162</sup> See, for example, Plant, *Oversea Settlement* . . . (1951), p. 163.

<sup>163</sup> Moles, "Social security for migrant workers" (1964).

<sup>164</sup> Faulkner, *American Economic History* (1943), p. 370.

made legal only in 1885.<sup>173</sup> In Germany and Italy under fascist governments various restrictions were imposed which greatly reduced emigration.<sup>174</sup> Most of the Socialist countries of Eastern Europe and the USSR are among the countries which currently discourage emigration.<sup>175</sup>

77. Governments of certain European countries which have experienced much emigration, most of it beneficial to their economies in the past, had by the 1960s adopted policies aimed at checking the outflow. Measures were taken by Ireland, for example, which were intended to increase the number of families who could be established on the land in economic security. In Greece, the Government aimed to increase employment opportunities so as to encourage also repatriation of Greek workers who had emigrated.<sup>176</sup>

78. Prohibition of emigration or special provisions relating to emigration sometimes apply only to certain categories of residents of a country. For example, the borders of South-West Africa are closed to "non-Europeans" except on production of individual permits.<sup>177</sup> Some Governments have refused to allow the emigration of specified categories of workers, either in order to protect the workers against possible exploitation abroad or because the departure of these workers might be economically undesirable for the country concerned. In 1922, for instance, the Government of India promulgated an Indian Emigration Act, which placed severe restraints on the emigration of unskilled labour.<sup>178</sup> More recently, the control of emigration of unskilled labourers from Angola, Malawi, Mozambique, and Zambia to South Africa has been exercised through the joint activities of the Governments concerned and recruiting organizations.<sup>179</sup> While Governments of many developing countries have misgivings about the emigration of professional and skilled workers and the loss of students who remain in developed countries following completion of their training, few have adopted formal policies to combat such emigration.<sup>180</sup>

79. Britain has been one of the few Governments which at various times has taken concrete measures to encourage emigration. Considerable activity in this respect occurred

around the middle of the nineteenth century when public funds were used to assist indigent emigrants, the dual object being to relieve population pressure in the mother country and at the same time strengthen ties with the colonies. The policy was revived after the First World War.<sup>181</sup>

80. More recently, several Governments have actively encouraged permanent emigration. Malta assists financially those who express a desire to emigrate, and that Government's application for membership in the Intergovernmental Committee for European Migration in 1962 was motivated in part by the wish to gain the maximum co-operation of other Governments in expanding emigration from the country.<sup>182</sup> As mentioned above, the Netherlands officially assisted emigration for a time after 1945. Mauritius also encourages emigration, though no financial assistance is given to prospective emigrants.<sup>183</sup> In Jamaica, the post-independence development plan stated that "it has long been Government's policy not to discourage citizens from migrating, and this Government has already declared its policy of exploring new migration outlets".<sup>184</sup>

81. Following the Second World War, the Italian Government embarked upon an active programme to encourage emigration. Agreements were reached with a number of European and overseas countries for the recruitment of Italian workers and the facilitation of their emigration.<sup>185</sup> Governments of other Southern European countries, including Yugoslavia, have also contracted treaties with Governments of Western European countries relating to the employment of their workers.<sup>186</sup>

82. Ceylon provides an example of a case where a Government has encouraged the emigration of a particular segment of its population. According to an agreement reached with India in 1964, about half of the estimated close to one million persons of Indian origin in Ceylon who were without Ceylonese citizenship were to be repatriated to India over a period of fifteen years.<sup>187</sup>

#### (b) Policies concerning immigration

83. The policies followed in countries of immigration have had on the whole a much greater influence upon modern migrations than the policies of emigration countries. There are few countries which have placed no restrictions on the numbers of immigrants who may enter, or upon the activities of the immigrants after arrival. On the other hand, public authorities have often taken measures to encourage immigration.

<sup>173</sup> Davie, *World Immigration* ... (1947), pp. 10, 305-306, 318; see also Ishii, *Population Pressure* ... (1937), p. 189.

<sup>185</sup> Eldridge, *Population Policies* ... (1954), p. 82. Australia, Brazil, the Federal Republic of Germany and Switzerland were among the countries with whom agreements were negotiated. Intergovernmental Committee for European Migration, "Italian emigration ..." (1966), pp. 123-124.

<sup>186</sup> Yugoslavia had such agreements with Austria, France and Sweden. Sauvy, "L'émigration yougoslave" (1967), p. 131.

<sup>187</sup> For a summary of the agreement, see Kodikara, *Indo-Ceylon Relations since Independence* (1965), pp. 140-143.

(i) *Prior to the Second World War*

84. The public land policies followed by the Governments of leading countries of immigration in the nineteenth century are an example of measures taken to stimulate immigration. In the United States, the Homestead Act of 1862 made agricultural land available free to settlers under certain conditions,<sup>188</sup> and policies to provide land at little or no cost for immigrants were also adopted by Canada and New Zealand.<sup>189</sup> The Governments of Brazil, Argentina, Australia, New Zealand and some other countries have at various times paid all or part of the cost of transportation for their immigrants, or have loaned them passage money.<sup>190</sup>

85. After the First World War, and particularly during the depression of the 1930s, the policies of countries of immigration shifted in the direction of limiting the inflow of foreigners. In country after country, severely restrictive laws were enacted with the objective of protecting the domestic labour market from the competition of immigrant workers. Some of the restrictive measures adopted were designed simply to reduce the numbers of immigrants, while others were aimed at a selection of groups thought to be more economically and socially desirable. Among the measures adopted were head taxes, annual immigration quotas, requirements as to health, literacy and linguistic abilities, assured employment or means of support, and limitations on the kinds of work in which immigrants could engage.<sup>191</sup> Occupational selection operating through legislation became an increasingly important element in immigration policy beginning in the 1920s, and particularly after the economic crisis in the 1930s.<sup>192</sup>

86. In the United States, legislation passed in 1921 and 1924, established annual quotas for immigrants of each nationality. With worsening economic conditions in the 1930s, immigration was further limited by a strict interpretation of existing legislation which provided for the exclusion of persons likely to become public charges.<sup>193</sup> Under the laws of practically all European countries, the immigration authorities were able to decide which persons should be admitted to the country, and this power was used, particularly during the 1930s, to restrict immigra-

tion and to admit, as a general rule, only those immigrants who were able to support themselves.<sup>194</sup> The laws adopted by the British Dominions favoured Northern and Western European, and especially British immigrants, but even their entry was governed by economic criteria; other immigrants, and particularly Asians, were kept to a minimum by means of dictation tests, prohibitive head taxes, quotas, or direct exclusion clauses.<sup>195</sup> In Latin America, restriction of immigration on the basis of economic considerations, which became general after 1929, was accomplished by such means as setting quotas, raising consular fees, abolishing or reducing exemptions from customs duties, and favouring, directly or indirectly, persons likely to engage in agricultural occupations.<sup>196</sup> In Asia, antagonism towards certain foreign minority groups (for example the Indians and Chinese), aggravated by the depression of the 1930s, has resulted in increasingly restrictive immigration laws in the principal immigrant-receiving countries of that continent. In 1941, Indian emigration to Burma was restricted by an agreement between the two Governments, and a similar agreement was concluded later on between India and Ceylon. In Malaysia (Federation of Malaya), Indian immigrants are now required to apply for entry permits, which are granted to those who can produce a guarantee of employment. Quota systems or other restrictions also limit the volume of immigration into Thailand, Indonesia and the Philippines. The effect of the various measures has been to put a stop to the massive immigration of Indians and Chinese in South-East Asian countries.<sup>197</sup>

(ii) *Following the Second World War*

87. Recent legislation in many of the countries of long-standing immigration has accorded preference to immigrants possessing certain qualifications or skills in short supply among the native labour force. The United States, Canada and Australia—all of which had previously favoured immigrants from Europe, and discriminated against those from other continents, particularly Asia—introduced changes in their immigration legislation which shifted the emphasis away from national origin of the immigrants to the skills which the potential immigrants possess. These changes have occurred partly as a response to various pressures against racial or national-origin discrimination, and partly because of the need for well-defined industrial and professional skills and the disappearance of traditional European sources of skilled workers.<sup>198</sup>

<sup>198</sup> See, for example, the explanation of the 1962 changes in Canada's immigration regulations given in Fairclough, "Social implications of the new ..." (1962).

88. With the increasing emphasis which the leading countries of immigration have placed on obtaining migrants who possess certain skills and professional and technical qualifications, and the relaxation of racial or ethnic barriers, the outflow of trained personnel from developing countries has become a matter of international concern.<sup>199</sup> Governments are involved in these movements, since employment is frequently offered to these highly qualified personnel by government-controlled organizations and organizations engaged in government-supported research.<sup>200</sup> It has therefore been argued that various measures, both national and international, be considered to reverse the movement or to mitigate its harmful effects.<sup>201</sup>

89. Up to 1962, Canada's immigration regulations restricted unsponsored immigrants to two categories: (a) British subjects by birth or naturalization in the United Kingdom or the old Commonwealth countries, and citizens by birth or naturalization of France, Ireland and the United States; and (b) citizens from Western European countries and refugees from Europe selected by the Department of Immigration for placement in employment or self-establishment in agriculture, business or industry in Canada.<sup>202</sup> The new Canadian immigration regulations of 1962 removed the previous ethnic preferences and, instead, emphasized the education, training, skills or other special qualifications of unsponsored applicants for immigration. Provision is also made for the entry of persons bearing prescribed degrees of relationship to Canadian residents.<sup>203</sup> Further revisions in immigration regulations were made in 1967. A system of point ratings was established whereby potential immigrants who have no close relatives in Canada, can qualify for entry if they obtain a score of 50 points, based on such criteria as education, occupation, skill, age, fluency in English and French, area of intended residence in Canada, and the immigration officer's personal assessment of the applicant's adaptability, motivation and initiative.<sup>204</sup>

90. In the United States, the long-established national-origin basis of quota allocation was abolished by 1965 legislation and, with it, the discriminatory quotas allocated to the so-called Asia-Pacific Triangle. Seven preference categories are established under the new legislation. The first, second, fourth and fifth preference categories pertain

to relatives of citizens or resident aliens, while the seventh refers to refugees. The third preference covers members of the professions, or persons of exceptional ability in the sciences or arts, and the sixth preference to skilled or unskilled persons who are able to fill labour shortages in the United States. The 1965 Act requires as a condition for admission of third and sixth preference immigrants that the Secretary of Labour must find that there are not sufficient workers in the United States who are qualified and willing to perform such work, and that the employment of the immigrants will not seriously affect the wages and working conditions of other workers similarly employed.<sup>205</sup> Brinley Thomas has suggested that one of the results of the basic alteration in the principles of selection of immigrants by the United States will be to intensify "the process of creaming off skills from the poorest areas of the world . . .".<sup>206</sup>

91. Immigration has been an integral part of economic policy in Australia since the Second World War, annual targets being set according to current and prospective demand for labour. For security reasons the Government has wished to attain the maximum population growth which could be effectively absorbed, calculated to average about 2 per cent annually. Natural increase was expected to account for a population growth of 1 per cent, and the remaining 1 per cent became the immigration target.<sup>207</sup>

92. Conditions in the United Kingdom, the traditional source of immigrants to Australia, were not conducive to large-scale emigration in the late 1940s, and Australia had to look elsewhere to attain her immigration target.<sup>208</sup> State-assisted immigration, which before 1946 had been restricted almost entirely to British subjects, was extended to other Europeans, as a result of displaced persons' immigration in 1949-1951. Agreements were also entered into with a number of European Governments. Dutch, German, Greek, Italian and Maltese settlers figured prominently in the non-refugee post-war immigration.<sup>209</sup>

93. The new Australian policy introduced in 1966 permits the admission of some non-European immigrants, who would become eligible for naturalization after five years in the same way as European settlers. Those so admitted are required to be qualified people needed by the Australian community and it is not envisaged that the numbers admitted would be sufficient to affect the homogeneity of the population.<sup>210</sup>

94. In New Zealand, although pre-1920 legislative restrictions were based on ethnic criteria, later legislation gave importance to economic criteria, for example the need for persons possessing specific skills. In actual fact, however, only small numbers of Asians have been admitted for permanent settlement.<sup>211</sup>

95. The sharp increase in the number of migrants from the Caribbean, India and Pakistan to the United Kingdom in the 1950s and early 1960s led to the passage of the Commonwealth Immigrants Act of 1962 which imposed restrictions on the volume of migration from the Commonwealth countries for the first time. With the exception of dependants of immigrant workers already resident in the United Kingdom, immigrant vouchers under the new legislation were issued only to those, skilled or unskilled, who had a specific job offer, and to persons with special qualifications or skills such as doctors, nurses and teachers. The number of Commonwealth immigrants allowed to enter each year was left to the discretion of the Home Secretary.<sup>212</sup>

96. In the period between the two world wars, a number of bilateral treaties were concluded between Governments providing for migration under conditions that were considered beneficial to both the countries of immigration and emigration.<sup>213</sup> After the Second World War, the practice of regulating international migration through bilateral agreements increased further. These agreements contained provisions for the selection and placement of the migrant workers by the authorities of the receiving countries and for reducing the administrative formalities of departure and entry.<sup>214</sup> For example, by 1964 France had established missions in Italy, Morocco, Portugal and Spain to facilitate the emigration of workers from those countries to France, and in 1965 accords were concluded with Turkey and Yugoslavia.<sup>215</sup> Similarly, the Federal Republic of Germany signed agreements with Greece (1960), Spain (1960) and Turkey (1961), among others.<sup>216</sup>

97. In the early post-war period, restrictions on the occupations which immigrants could pursue were commonplace in Western Europe. Immigrants were permitted to work only in occupations where the national labour force was insufficient and very often they were prohibited from moving out of these occupations for a specified period of time. Strict control over the employment of foreign workers was made possible by the granting and renewal of work permits. A situation developed in which special advantages were granted to particular nationalities, either as a result of bilateral or multilateral agreements among the Governments concerned, or through the development of various European regional organizations. For example, the treaty establishing the European Coal and Steel Community in 1951 specified that there should be free circulation between member States of workers with recognized qualifications in these industries.<sup>217</sup>

<sup>216</sup> Reid and Hunter, "Integration and labor mobility" (1967), p. 187.

<sup>217</sup> International Labour Office, *International Migration* . . . (1959), pp. 214-217. As early as 1954, Denmark, Finland, Norway and Sweden had established a common employment market and, since 1960, work permits for employees in private industry have

98. Regulations governing the employment of nationals of member States within the European Economic Community have been progressively liberalized since its establishment in 1957. In October 1968 the Council of the European Communities approved regulations which prohibit discrimination with respect to employment, wages and other conditions of work among nationals of member States, and establish the right of such workers to free movement within the Community for purposes of employment. Machinery was also set up for matching job vacancies and applicants among the member States.<sup>218</sup> It is difficult to assess the effects of the several regional economic integration schemes in operation in Europe, as well as the effects of the various bilateral and multilateral agreements, on the volume of labour mobility among the participating countries.<sup>219</sup>

99. Qualitatively selective immigration has become the goal in Latin America, where neither the general educational system nor the vocational training of adults is sufficient to meet the requirements for the professional and skilled manpower essential for development. Thus, a strong need exists to import such manpower, but attempts to fill these gaps with immigrants from Europe have been to a large degree frustrated by inadequate financial resources and the lack of administrative structures for the recruitment and placement of the desired personnel.<sup>220</sup> Moreover, the Latin American countries have not been able to compete effectively with "the pull of the industrially advanced countries", such as the United States and Canada, in attracting the type of immigrant desired.<sup>221</sup>

100. Israel appears to be the only country in Asia with a positive policy of encouraging immigration. Israel accepts all Jewish immigrants without question, in accordance with her Proclamation of Independence of 14 May 1948. While the Israel Government and the Jewish Agency are prepared, as in the past, to cope with mass immigration in the event of an emergency or a relaxation of restrictions on Jewish emigration from countries where it has been blocked, in recent years increasing attention has been devoted to attracting immigrants from the Western countries, many of whom possess professional and technical skills which are in short supply in Israel.<sup>222</sup> In most countries of Asia the volume of international migration in the post-war period has been small, though

not been necessary for nationals of Benelux countries for work in the other member countries. Reid and Hunter, "Integration and labor mobility" (1967), pp. 190-191.

<sup>218</sup> International Labour Office, "Free movement of workers . . ." (1969).

<sup>219</sup> For a discussion of this subject, see Reid and Hunter, "Integration and labor mobility" (1967).

<sup>220</sup> Maselli, "Immigration as an essential element . . ." (1967). Legislative provisions in certain Latin American countries have given preference to agricultural and other workers in rural industry. In Brazil, for example, immigration legislation requires that 80 per cent of immigrants admitted under the quota system must in principle be farm or rural industry workers. The attraction of agricultural settlers has also been a feature of immigration policy in Argentina. International Labour Office, *International Migration* . . . (1959), p. 223.

<sup>221</sup> Besterman, "Immigration as a means . . ." (1967).

<sup>222</sup> Jewish Agency, *16 Years of Immigration to Israel* (1964).

the import of highly skilled and professional workers on a temporary basis is a feature of official development policy in some countries.<sup>223</sup>

101. In Africa, the appearance of newly independent States has led to some limitations on migration across national boundaries, despite the incompatibility of such restrictions with the ideology of Pan-Africanism. It has been pointed out that controls on immigration may increasingly be imposed both to foster feelings of national consciousness as well as to protect the interests of the native labour force.<sup>224</sup> The South African Government's policy with respect to European immigration changed several times in the period following the Second World War. The United Party actively encouraged immigration from 1946 to 1948; this policy was reversed when the Nationalist Party came to power in 1948, but a few years later the Nationalists dropped their opposition to immigration. In 1961 the Government adopted new measures designed to attract 30,000 white immigrants annually.<sup>225</sup> Preference is given to British subjects of European extraction, but other Europeans who are likely to make economically or socially useful contributions to the community are also admitted. The permanent immigration of persons considered incapable of being integrated into the white population is completely banned.<sup>226</sup>

### C. The effect of immigration and emigration on the growth and structure of populations

#### 1. THE EFFECT ON POPULATION GROWTH

102. Migration exerts a direct effect upon the growth of population which may be large or small depending on the relative size of the migrant and non-migrant populations. It has been customary in many studies to examine the effect of migration by comparing its net volume with natural increase, the other component of population growth. Until the latter part of the nineteenth century, net immigration was the major factor of population growth in some of the overseas countries of European settlement which had small populations. For example, it contributed more than natural increase to total population growth in Australia before 1860 and in New Zealand during most periods before 1875. At the time natural increase replaced net immigration as the major factor of growth, the population of New Zealand was about half a million, while that of Australia had reached about the one million mark. Even though surpassed by natural increase in later years, migration remained an important

element in the growth rates of these countries which for long periods exceeded 2 per cent per annum.<sup>227</sup>

103. In the United States, during each decade 1850-1900, estimates suggest that for every 100 persons added to the population through natural increase, the gain through net migration ranged from twenty to forty persons.<sup>228</sup> Canada, while admitting many new immigrants, has traditionally lost large numbers through emigration. In only five of the ten decades between 1851-1951 was there a net gain through migration, and the ratio of net migration to natural increase was sizable only in the early years of the twentieth century.<sup>229</sup> The seemingly modest contribution of immigration to Canada's population growth is misleading, however, since a considerable proportion of the emigrants from Canada have been Canadian-born.<sup>230</sup> According to one estimate, net immigration during the century 1851-1951 amounted to only 700,000,<sup>231</sup> but the number of foreign-born persons enumerated at the 1951 census was as high as 2.1 million (or one out of seven persons), and had risen to 2.8 million (or almost one out of six persons) at the 1961 census.<sup>232</sup> Net immigration was only a secondary factor in the growth of Brazil's population, amounting to less than 10 per cent of natural increase from 1850 to 1950.<sup>233</sup>

104. High ratios of net immigration to natural increase have been recorded in a number of countries of overseas settlement in the period following the Second World War. During the period 1946-1957, for every population gain of 100 through natural increase, there were gains through net migration of sixty-seven in Australia, forty-one in New Zealand, and thirty in Canada. In the principal countries of immigration in Latin America this ratio was lower; for example, it was twenty-three in Argentina and sixteen in Venezuela. The comparable figure for the

<sup>227</sup> Data on population growth and relative contribution of migration to this growth in various periods are given for New Zealand in Landry, *Traité de démographie* (1949), pp. 65, 433; and for Australia in Borrie, *Population Trends and Policies ...* (1948), p. 38. For Australia, see also Geyl, "A brief history ..." (1963), pp. 157-158.

<sup>228</sup> Computed from data in Willcox, "Immigration into the United States" (1931), pp. 89, 97. The estimates of net migration presented by the author were admittedly crude. Using a method which compared the increases in the foreign-born and total population during intercensal periods, Kuznets and Rubin assessed the immigration factor in total population growth in the United States between 1860 and 1940. Kuznets and Rubin, *Immigration and the Foreign Born* (1954), pp. 4, 44-45.

<sup>229</sup> Keyfitz, "The changing Canadian population" (1961), p. 7; and his "The growth of Canadian population" (1950). For varying estimates of the relative contributions of immigration and natural increase to Canadian population growth, see also McDougall, "Immigration into Canada, 1851-1920" (1961), p. 172; and Camu, Weeks and Sametz, *Economic Geography of Canada ...* (1964), pp. 58-59.

<sup>230</sup> From 1851 to 1951 this proportion was possibly two-fifths. Ryder, "Components of Canadian population growth" (1961), pp. 60, 62. See also Corbett, *Canada's Immigration Policy ...* (1957), p. 121.

<sup>231</sup> Keyfitz, "The changing Canadian population" (1961), p. 8.

<sup>233</sup> Mortara, "The development and structure ..." (1954), p. 122.

<sup>223</sup> Appleyard, "Immigration policies and economic development ..." (1967).

<sup>224</sup> Wallerstein, "Migration in West Africa ..." (1965), pp. 157-159; Caldwell, "Migration and urbanization" (1967), pp. 119-121, 145; Gil, "Immigration into Ghana ..." (1967).

<sup>225</sup> Richards, "Problems of economic development ..." (1964), p. 277.

<sup>226</sup> International Labour Office, *International Migration ...* (1959), p. 226.

United States was only eight.<sup>234</sup> Israel is unique as a new and almost wholly immigrant country; in the period 1948-1960 the increase in the Jewish population from immigration was more than twice that of natural increase.<sup>235</sup>

105. In the major immigrant countries of Europe, the volume of net immigration in relation to natural increase exceeded that in many of the overseas countries. According to the data presented in table VII.1, the ratio of net immigration per 100 population gain through natural increase was 100 in the Federal Republic of Germany, eighty in Switzerland and thirty-eight in France during 1950-1960. The comparisons with overseas countries are, however, affected by the generally higher level of natural increase in the latter. Average annual net immigration constituted a higher percentage of total population in Australia, Canada and New Zealand (1.0, 0.7 and 0.7, respectively, during 1946-1957) than it did in Switzerland, the Federal Republic of Germany and France (0.6, 0.5 and 0.3, respectively, during 1950-1960).<sup>236</sup>

106. Net emigration had an important effect in moderating the growth rates of certain European countries during the nineteenth and early twentieth centuries. For Europe as a whole, it has been estimated that one fifth of natural population increase was lost through emigration during the nineteenth century.<sup>237</sup> The most striking example is, of course, Ireland, where emigration far exceeded natural increase, and the total population declined from over 5 million in 1851 to less than 3 million in 1926.<sup>238</sup> Losses from emigration amounted to as much as one third of natural increase in the Scandinavian countries from 1861 to 1910.<sup>239</sup> In Germany, between 1841 and 1910, and in the United Kingdom, between 1871 and 1931, net emigration amounted, on average, to about one seventh and one sixth, respectively, of the natural increase, though in certain periods in each country, the proportion was much higher.<sup>240</sup>

107. In recent years, losses of population through emigration have been considerable in Ireland, in the German Democratic Republic and in certain countries of Southern Europe. Between 1959 and 1969, net emigration was two and one-half times the gain through natural increase in the German Democratic Republic, and one and one-half times in Ireland, while Malta lost the

equivalent of 70 per cent of its natural increase, Portugal 60 per cent, Italy 30 per cent, Spain 25 per cent, and Greece and Yugoslavia about 20 per cent.<sup>241</sup> In Greece the net emigration loss was greater in more recent years; for 1960-1965 it has been estimated to amount to nearly three fourths of the natural increase.<sup>242</sup>

108. In the case of certain small populations, emigration has been on a sufficient scale in recent decades to effectively slow the rate of population growth. This has been true, for example, in Barbados and Jamaica, as well as several other small islands in the Caribbean area, and in Gibraltar and Malta in the Mediterranean.<sup>243</sup> The decline in Puerto Rico's population growth rate to 0.6 per cent per annum during 1950-1960 was largely attributable to emigration.<sup>244</sup>

109. Despite the inadequacies of statistical data for most countries of Africa and Asia, it seems probable that migration movements have generally had a less marked effect on population growth in those regions than in areas of European migrations since the movements have generally been small in relation to the total populations of sending and receiving countries. Moreover, they have been to and from countries with high rates of natural increase and have therefore not constituted a large component of population growth. Important exceptions exist, however, in such immigrant countries as Ghana, Rhodesia and South Africa, as well as Manchuria and Hong Kong, as mentioned earlier.

110. Many studies have been concerned, not with just the immediate effects of adding or subtracting a given number of migrants from a country's population, but with the long-term effects of such migration which take into account the permanency of the migration and the natural increase of the migrants. Obviously, immigrants who return to their home countries, taking along any children who may have been born to them during their stay, can have only a transitory influence on population in the area of immigration. The overseas immigration of Europeans has been to a large extent permanent, while much of the migration in Africa and Asia and within Europe during recent times has consisted of workers seeking employment for a period of months or years, and thus has had relatively little influence on population growth. The migrations which were organized in the second half of the nineteenth century and the early decades of the twentieth to provide a low-cost supply of labour in certain areas specializing in the production of raw materials, varied in the extent of their permanence. In some cases, the immigrants remained in sufficient numbers so that they and their descendants formed an

<sup>234</sup> International Labour Office, *International Migration* ... (1959), pp. 308, 312. The fact that the ratio for Argentina surpassed that for Venezuela is related to the latter's higher rate of natural increase. In relation to total population size, net immigration was larger in Venezuela.

important segment of the population, as, for example, the East Indians in the West Indies.<sup>245</sup>

111. Owing to sex-age selectivities, migration often tends to increase population growth rates in the receiving countries. Generally, migrant streams have a high proportion of young persons in the reproductive ages where mortality rates are low. Moreover, the small excess of males which has been typical of many migrations of Europeans has helped to ensure high marriage rates among immigrant women. Where intermarriage is common, a high ratio of males among immigrants may also increase the marriage opportunities of the native women in the receiving country, thus accelerating natural increase. This was the case in France in the 1920s when immigration helped to correct the imbalance of the sexes that had resulted from heavy war losses.<sup>246</sup> If there is little intermarriage, however, a preponderance of male immigrants might result in many of them remaining unmarried, thus tending to reduce the natural increase rate of the immigrant group. A case in point is the migration of Chinese in Asia and the Western Pacific region, since such migrations were predominantly male, and there was relatively little intermarriage between Chinese men and local women.<sup>247</sup> In Malaysia (Federated and Unfederated Malay States and the Straits Settlements), after restrictions were imposed on further Chinese male immigration in 1933 and the sex ratio became more balanced, the crude birth rate increased fairly steadily.<sup>248</sup>

112. The contribution of migrants to population growth also depends on their age-specific birth and death rates.<sup>249</sup> While the immigrants themselves may sustain the fertility patterns of their areas of origin, the subsequent generations tend more and more to conform with the

patterns of the receiving areas.<sup>250</sup> European migrants have frequently gone to settle in areas of higher fertility; in Australia, at least, they appear to have sustained their lower fertility rates.<sup>251</sup>

113. Several studies have been concerned with the total contribution of immigration and the natural increase of immigrants to the growth of population in individual countries. Landry estimated that migrants and their descendants contributed well over one third of the population increase of France from 1801 to 1936.<sup>252</sup> For the century from 1840 to 1940 it has been estimated that immigrants and their natural increase accounted for nearly 60 per cent of population growth in Argentina, 40 per cent in the United States, and only about 20 per cent in Brazil and Canada.<sup>253</sup>

114. Just as migration, because of its sex-age selectivities, tends to raise the proportions of married women and increase population growth rates in the receiving areas, it tends to reduce them in the sending areas. Thus, emigration has been advanced as one of the causes of declining birth rates in recent years in some Southern European countries as well as in Ireland and in Puerto Rico.<sup>254</sup> In Africa, the absence of large numbers of migrant males for extensive periods is sometimes held to have a depressing effect on fertility rates in their home areas, but the question is complicated by traditional attitudes which may condone the wife's having sexual relations with other men during the husband's absence, in the interest of bearing as many children as possible.<sup>255</sup> Emigration from the heavily populated countries of

<sup>245</sup> On the other hand, Davis found evidence of a high return rate for Indian migrants in some areas. According to his estimates, the number of Indians residing in Burma and British Malaya in 1941 was considerably less than the number who migrated there during the previous century. Davis, *The Population of India and Pakistan* (1951), p. 101.

<sup>246</sup> Kirk, *Europe's Population* ... (1946), p. 117. In Australia, the surplus of males among immigrants in the period following the Second World War is believed to have been an important factor in the great increase in the proportion of women married. Borrie and Spencer, *Australia's Population Structure* ... (1965), pp. 21-22.

<sup>247</sup> United Nations, "International migrations in the Far East ..." (1951), p. 19. It was found that the exceedingly high proportion of males among the Chinese-born population in Australia did not result in extensive intermarriage with the white population. Borrie, *Italians and Germans in Australia* ... (1954), pp. 40, 42. On the other hand, there has been at times a considerable intermarriage of Chinese males with local women, as in Hawaii and Sarawak. Taeuber, "International migration ..." (1967), p. 242; Purcell, *The Chinese in Southeast Asia* (1965), p. 366.

<sup>248</sup> Smith, *Population Growth in Malaya* ... (1952), pp. 63, 78. Chinese females were admitted freely until 1938. *Ibid.*, p. 12.

<sup>249</sup> For example, the rapid increase in the Asian population of South Africa between 1921 and 1946 was attributed primarily to relatively low mortality and exceptionally high fertility. Badenhorst, "The future growth of the population ..." (1950), pp. 10-11. Slightly higher age-specific mortality rates for the foreign-born than for the native white population were found in the United States. Thompson and Whelpton, *Population Trends* ... (1933), pp. 246-247; and Davie, *World Immigration* ... (1947), pp. 229-230.

<sup>250</sup> Lorimer and Osborn, *Dynamics of Population* ... (1934), pp. 28, 41-43, 48-54; Thomas, "International migration" (1959), p. 530. In 1920, first-generation Italian women in the United States had a fertility rate about double that of the native-born white American women, but by the mid-1930s, the fertility rates of these groups were nearly identical. Livi Bacci, "Caratteristiche demografiche ed assimilazione ..." (1965), p. 25.

<sup>251</sup> Borrie and Spencer, *Australia's Population Structure* ... (1965), pp. 31, 33.

<sup>252</sup> Landry, *Traité de démographie* (1949), pp. 514-515.

<sup>253</sup> Spengler, "Effects produced in receiving countries ..." (1958), p. 26. Another estimate for Argentina suggests that if there had been no immigration since 1870, the population in 1960 would have been less than one half its actual figure. Recchini de Lattes, "Demographic consequences ..." (1967), p. 212. An estimate for the United States indicates that in 1920, the immigrant stock (defined as immigrants and descendants of immigrants arriving after 1790) outnumbered the descendants of the colonial white population, in spite of the rapid increase of the latter. United States of America, Congress, Senate, *Immigration Quotas* ... (1928), pp. 7-8. Mortara's calculations for Brazil for 1850 to 1950 show that net immigration and the natural increase of immigrants accounted for about 15 per cent of total population growth. Mortara, "The development and structure ..." (1954), p. 122.

<sup>254</sup> International Labour Office, *International Migration* ... (1959), p. 333; Friedlander, *Labor Migration and Economic Growth* ... (1965), pp. 72-73; Vazquez, *The Demographic Evolution* ... (1964), p. 194.

<sup>255</sup> Schapera, "An anthropologist's approach to population growth ..." (1955), pp. 27-28; also his *Migrant Labour and Tribal Life* ... (1947), pp. 187-189. Southall observes that areas in East Africa with the sexes evenly balanced and little migration tend to have higher growth rates than those with imbalance as a result of migration, but he adds that African male emigrants "make very deliberate efforts not to let their wives 'lie fallow' when left at home". Southall, "The demographic and social effects ..." (1967), p. 237.

Asia does not appear to have been sufficiently large to have any great long-term effect upon the growth of population in the countries of origin.<sup>256</sup>

115. Few attempts have been made to estimate how much larger the populations of the principal countries of emigration might have been, had there been no emigration. However, Novitsky and Tolokonsky estimated for Europe as a whole that the 1910 population would have been larger by some 88 million if no emigration had occurred between 1800 and 1910.<sup>257</sup> Skaug calculated for Norway the effects of the decrease in overseas emigration following the First World War.<sup>258</sup>

116. Finally, there is the question of the effect migration may have on the natural increase of the non-immigrant population. Walker's "substitution theory" held that immigration has no effect in the long run on the size of the population since the addition to numbers through immigration is offset by the depressing effect on the fertility of the native born.<sup>259</sup> He maintained that the slowing-down of the rate of natural increase in the United States after 1830 was due to the effects of immigration in lowering, or threatening to lower, the level of living of the native population.<sup>260</sup> The weight of evidence, however, is against Walker's theory. Thompson and Whelpton found that immigration did contribute to the lowering of the birth rate by hastening the processes of urbanization and industrialization, and by facilitating the upward occupational mobility of large numbers of natives. These authors demonstrated, however, that in any 10, 20 or 30-year period between 1830 and 1930 the increase due to immigration exceeded the decline of fertility and thus added materially to population growth.<sup>261</sup> The applicability of the theory to France was challenged on the grounds that the birth rate was low prior to the coming of the immigrants, and that it was low in many depart-

ments with few immigrants.<sup>262</sup> Yet another theory suggested that the increase in wealth resulting from immigration into the United States altered the relation between population and resources, and thus provided the basis for further population expansion.<sup>263</sup> It is now recognized that immigration may have indirect effects on the natural increase of the non-immigrant population, but the nature and extent of these effects vary with the situation and are not subject to generalization.

117. Theories similar to the "substitution theory" have evolved with respect to the effect of emigration on the natural increase of the sending areas. Kulischer, for example, believed that emigration, instead of draining off Europe's population, promoted its unprecedented growth.<sup>264</sup> Such a proposition implies that if emigration had not occurred, the growth of population would have been checked by a severe reduction in the level of living. Isaac, while acknowledging that emigration, when it affords real relief from population pressure, might have a stimulating effect on natural increase by leading to earlier marriages, higher fertility within marriage and a lower infant mortality rate, argued, on the other hand, that by bringing a higher level of living, emigration might lead to an outlook favourable to a lower birth rate. Taking into account the effects of the sex-age selectivities of migration which have been discussed above, he concluded that emigration had tended to reduce population growth in most European countries.<sup>265</sup>

## 2. THE EFFECT ON SEX AND AGE STRUCTURE

118. Ordinarily it has been found that migrants across international boundaries are predominantly young and male. The proportion of young men is usually high at the beginning of large-scale movements, and also in the case of temporary migration. It is likely to be higher in economic-motivated migrations than in movements of refugees. Intercontinental emigrations of Europeans have increasingly had a high proportion of family units so that the ratio of young adult males to other sex-age groups among the migrants has tended to decline. Restrictive legislation of the 1920s in the United States considerably affected the sex-age distribution of immigrants by giving preference to relatives of those who had come earlier. During the depression years of the 1930s the total volume of immigration was low, and the number of migrants going to seek employment declined more than the number going to join relatives. Entry of war brides into the United States was a factor contributing to the low sex ratios in the period after the Second World War. The following figures for three important countries of immigration illustrate how the sex and age structure of immigrants has changed over periods of the recent past.<sup>266</sup>

<sup>256</sup> See, for example, Chen, "Population in modern China" (1946), p. 57; Davis, *The Population of India and Pakistan* (1951), p. 106; United Nations, "International migrations in the Far East ..." (1951).

<sup>257</sup> This figure is based on the estimated number of survivors from the emigrants who left Europe during that period and their descendants who would be living in Europe if no migration had occurred. Novitsky and Tolokonsky, "Vliianie emigratsii na usloviia ..." (1929), pp. 97-98.

<sup>258</sup> Skaug, *Memorandum* ... (1937), pp. 136-154.

<sup>259</sup> Walker, "Immigration and degradation" (1891), and his "Restriction of immigration" (1896). Walker's statement of the theory was a modification of earlier formulations by French and English writers of the eighteenth century (see Landry, *Traité de démographie* (1949), pp. 519-524), and by Franklin, *Observations Concerning the Increase of Mankind* ... (1755; 1918 ed.), pp. 222-224. Franklin restricted his thesis to countries where the population was at a maximum that could be supported under existing economic arrangements (a reservation omitted by Walker), but he applied it both to eighteenth-century England and to colonial America. It was essentially a corollary of the Malthusian theory that population presses constantly on the limit imposed by the means of subsistence.

<sup>260</sup> Walker, "Restriction of immigration" (1896). See also Fairchild, *Immigration* ... (1925), pp. 215-225; and his "Immigration and the population problem" (1930), pp. 8-9. Some French writers felt that immigration would limit natural increase by restricting employment opportunities for the native population. See Bertillon, "Migration" (1873), p. 661.

<sup>261</sup> Thompson and Whelpton, *Population Trends* ... (1933), pp. 305-308.

Under sixteen

119. Intracontinental migrations within Europe, Africa and Asia have often been of a temporary nature and hence have had a lower proportion of family units and a larger proportion of young adult males. Not all such movements are marked by high masculinity rates, however. Figures suggest that Ireland has, at certain periods, sent more female emigrants to Britain than males, and that Sweden has received more female than male immigrants.<sup>267</sup>

120. Despite the age selectivities of migration, only movements on a massive scale are likely to produce major changes in the age structure of the population of the receiving country. In Malaya, at the time of the 1931 census, the percentage of population in the age group 20-34 years was disproportionately high (nearly one third of the population) as a result of the past heavy immigration of Indians and Chinese. Immigration later declined and by 1957 the proportion of total population in this age group had fallen to 21 per cent, while there was a rise in the proportion of children and older persons in the population.<sup>268</sup> A typical in its characteristics, the large-scale immigration into Israel between 1949 and 1953 had the effect of raising the proportion of children and elderly people in the population.<sup>269</sup> When the volume is relatively large, immigration, because of its age selectivities, can help to rectify deficits that have occurred in the population structure. Thus, immigration to Sweden in the post-war period has somewhat reduced the deficiency in the young adult population, who were born during a period of low fertility.<sup>270</sup> In France, immigration

has filled the gaps caused by war losses in both world wars, but serious deficits still exist in certain age groups, as a result of fewer children having been born to the generations which suffered the war losses.<sup>271</sup>

121. In overseas countries of immigration, such as Australia, New Zealand and the United States, low birth rates of the 1930s created a situation in the 1950s where the rate of increment to the working ages was small in relation to the rate of total population growth. These deficits were undoubtedly a factor sustaining the demand for immigrant workers, but since these workers were generally accompanied by their families, the growth rates of the young age groups as well as those of the working ages were affected. In Australia immigration had a substantial impact on all age groups up to at least fifty years during the period between 1947 and 1961 when immigration and natural increase to immigrants accounted for half of total population growth. Without any immigration, the population aged 15-64 years would have grown by only 8 per cent, compared with a growth of total population of 19 per cent. Immigration raised the growth of the working-age sector to 27 per cent, and the total population growth rate to 39 per cent.<sup>272</sup> As a result, the ratio of population in the working ages to total population was only slightly higher than it would have been had no immigration occurred.<sup>273</sup> In Argentina, between 1947 and 1952, a higher concentration of immigrants in the young working ages brought the proportion of total population in the 15-44 age group to 49 per cent in 1952 whereas it is estimated that it would have been no more than 47 per cent in the absence of immigration.<sup>274</sup>

122. The converse of the above pattern is that many of the emigrants from Southern European countries in recent years belong to age contingents which are "surplus" in the sense that they are the products of birth rates which were much higher twenty years ago than they are today. By removing some of these surpluses, emigration is believed to have reduced employment problems, particularly in rural areas, in countries with restricted capital for investment.<sup>275</sup> Emigration brought about a substantial ageing of the population of Malta and Ireland in the post-war period, and such an effect, though less pronounced, has also been observed in the populations of Italy and Portugal.<sup>276</sup>

<sup>271</sup> Sauvy, "Besoins et possibilités ..." (1950), pp. 218, 220; France, Ministère de l'économie et des finances, Institut national de la statistique et des études économiques, "La situation démographique en 1965" (1967), p. 7.

<sup>273</sup> *Ibid.*, p. 45.

<sup>274</sup> Computed from data in Pan, "Effects of recent and possible future migration ..." (1955), p. 144.

<sup>275</sup> Organisation for Economic Co-operation and Development, *International Joint Seminar on the Adaptation ...* (1965), pp. 49-59.

<sup>276</sup> International Labour Office, *International Migration ...* (1959), pp. 313-317. Other studies have examined the effects of emigration on age structure by means of population projections calculated on different assumptions concerning the flow of migration. Parenti and Bandettini found, for example, that emigration over a twenty-year period would be likely to reduce the proportion of population of working age only slightly in Italy and the Netherlands, and somewhat more in Portugal and Ireland. Parenti and Bandettini, (Continued on next page).

<sup>267</sup> International Labour Office, *International Migration ...* (1959), pp. 330-331.

<sup>268</sup> Computed from data in Smith, *Population Growth in Malaya ...* (1952), pp. 12-13; and United Nations, *Demographic Yearbook, 1960 ...* (1961), table 5.

<sup>269</sup> During this period the net increase in Jewish population through immigration was estimated at over 600,000 (including the natural increase of migrants), compared with a 1948 population of about 850,000. While the proportion of children under fifteen years of age would have risen from 28.8 to 31.7 per cent through natural growth, as a result of immigration it rose to 32.3 per cent. Sicron, *Immigration to Israel ...* (1957), pp. 58-59. See also Bachi, "Immigration into Israel" (1958), pp. 324-326.

<sup>270</sup> International Labour Office, *International Migration ...* (1959), pp. 318-319.

123. The effects of a large-scale emigration over a considerable period of time upon the age structure of the population is illustrated by a comparison of the age distributions of Ireland for the years 1881, 1946 and 1961. Owing to emigration there was a pronounced "hollow" in the Irish age pyramid from about age 20 to about age 45 both in 1881 and in 1961. In contrast, the age pyramid for 1946 was more regular, because of the lower rate of emigration in the decades preceding that census.<sup>277</sup>

124. In the majority of countries the volume of immigration or emigration has not been sufficient to greatly affect the age structure of the population. The effects of migration on the age structure of populations have been examined in some studies by use of the method of constructing hypothetical models or through illustrative projections of actual populations. The findings of such studies are examined in the following chapter.

#### D. Economic effects of migration

125. Immigration or emigration, through its effect on the size and structure of the population, may influence the growth of the economy and the levels of living in the countries concerned. Only certain aspects of the extensive literature on the economic effects of migration are discussed here. These include: (a) effects on the labour force; (b) effects on employment and unemployment; (c) effects on wage levels; and (d) effects on the balance of payments. In addition, the present chapter summarizes the findings of studies concerned with the economic effects of selected migrations in the period following the Second World War. Other economic aspects of immigration, such as its effects on investment and productivity are discussed in chapter XIII.

##### 1. EFFECTS ON THE LABOUR FORCE

126. Immigration may affect the relative size of the work force in two ways: through its effects on the population's sex-age structure (since as pointed out in section C above, migrant streams very often have a high proportion of males in the young working ages), and through differences in labour-force participation rates between immigrants and non-immigrants in the same sex-age group. In the United States between 1890-1940, these rates were generally higher among foreign-born white men than among native white men, although the opposite tendency was true for women beginning in 1920.<sup>278</sup> When account

is also taken of the favourable age structure of the immigrants, it is clear that the effect of immigration into the United States was to increase the ratio of the economically active to the total population. In Venezuela, the post-war stream of immigrants had an extremely high proportion of workers; the 1961 census data show that about two out of three of the immigrant population were economically active, as compared with about three out of ten in the native population. Variations in age structure between the two groups provide the main explanation for these differences,<sup>279</sup> but higher age-specific activity rates for immigrants appear also to be a factor.<sup>280</sup> In Canada, immigration has increased the relative size of the economically active population almost entirely because of the concentration of the foreign-born in the most productive ages, rather than because of higher age-specific activity rates among them.<sup>281</sup>

127. Not all immigrant streams have contributed more to the active than to the inactive population, however. In particular, migrations motivated by other than economic considerations are less likely to have such an effect. In Israel, for example, immigration during the period immediately after independence tended to lower the ratio of workers to dependants, owing to the higher proportion of immigrants in age groups 15-19 and 45 years and over, where activity rates are lower, and to the extremely low activity rates among female immigrants from Africa and Asia.<sup>282</sup> The expellees in West Germany in 1950 had a slightly higher proportion of their numbers in the working ages than did the remainder of the population; but the unfavourable employment situation of that time tended to limit the labour-force participation of women, older workers, and the self-employed among the expellees, with the result that their economic activity rate was lower than that of the rest of the population.<sup>283</sup>

128. The impact of migration upon the occupational distribution of the labour force is frequently difficult to establish in view of the inadequacy of available statistical information. It is often uncertain whether the occupation reported by an immigrant on his arrival relates to the occupation exercised in the country of origin or to that which he intends to follow in the receiving country.<sup>284</sup> The evidence shows that the occupa-

<sup>279</sup> Venezuela, Oficina Central del Censo, *Noveno censo general de población* . . . , parte A (1966), pp. 45, 140-145.

<sup>280</sup> Venezuela, Oficina Central del Censo, *Noveno censo* . . . (1964), pp. 116-121.

<sup>281</sup> In 1961, nearly half the immigrant population was economically active, compared with only about one third of the Canadian-born population. See Canada, Dominion Bureau of Statistics, *1961 Census of Canada* . . . , bulletin 1.3-4 (1963) and *1961 Census of Canada* . . . , bulletin 3.2-10 (1964). The higher proportions economically active among foreign-born Canadians observed at earlier census dates were also a result of their heavier concentration in the working ages as compared to the native population. See Hurd, *Racial Origins and Nativity* . . . (1937), p. 171.

<sup>278</sup> Durand, *The Labor Force in the United States* . . . (1948), pp. 210-213. The lower activity rates for foreign-born females were believed to be related to their higher fertility and differences in cultural background. *Ibid.*, p. 53.

tional composition of immigrants varies with their national origins and with the period of migration.<sup>285</sup> The earliest emigrants from Europe were predominantly small farmers and agricultural labourers, but industrial workers took an increasing part in the movement. Among British emigrants in the latter half of the nineteenth century, the number of "labourers" exceeded agricultural workers by large margins.<sup>286</sup>

129. Immigration statistics for the United States for the period 1899-1915 suggest that about one quarter of the immigrants from Eastern and Southern Europe and only about 10 per cent of those from Western and Northern Europe had been engaged in agriculture prior to emigration. On the other hand, roughly one third of the immigrants to Argentina during 1901-1910<sup>287</sup> and to Canada during 1921-1925 were agricultural workers.<sup>288</sup> Immigrants often have not followed the same occupations, in their adopted countries, as before their migration.<sup>289</sup> During the last decade of the nineteenth century over two fifths of all emigrants from Italy were reported to have been farm workers,<sup>290</sup> but relatively few of the Italian-born population in the United States were employed in agriculture. In fact, next to the Hungarians, Italians were the least agricultural of the various immigrant groups living in the United States at the turn of the century. The immigrant population as a whole was relatively lightly represented in agriculture and heavily concentrated in the less skilled occupations in manufacturing and allied industries.<sup>291</sup>

130. The type of occupational opportunities available in the country of immigration appears sometimes to have exercised a strong influence on the occupational type of immigrants attracted. Thus, the occupations listed by overseas immigrants to New Zealand between 1921 and 1924 bore a marked similarity to the occupational distribution of the total population at the 1921 census.<sup>292</sup> In some countries, there has been a tendency for dis-

proportionately large numbers of immigrants to enter "unpleasant" jobs which failed to attract sufficient numbers of the native population.<sup>293</sup>

131. In recent decades, Governments have increasingly practised occupational selection in admitting immigrants and have prevented them from engaging in certain lines of work. More and more the demands have been for skilled rather than unskilled workers and, in this respect, both sending and receiving countries are competitors for a scarce resource.<sup>294</sup> Shortages are partly the result of the low birth rate in the 1930s and war casualties, but they also reflect the revolutionary changes which have taken place in technology, calling for greater skills on the part of the work force.<sup>295</sup>

132. Sometimes the heavy demands for middle and upper classes of manpower have created a situation where there is a rapid upward mobility of the native population, as they acquire education and equip themselves with the necessary skills, and the occupations requiring lower skills are left to immigrants.<sup>296</sup> This substitution effect appears to have been particularly in evidence since the Second World War, when relative stability in the size of the non-immigrant work force, increasing real incomes, technological developments, and greatly increased expenditure on education have combined to accelerate the opportunities for upward mobility of the non-immigrant work force, and at the same time have opened up avenues for employment of immigrants.<sup>297</sup>

133. Overseas emigrants from Europe in the post-war period have included an increasingly larger proportion of skilled persons,<sup>298</sup> partly owing to the highly organized recruitment processes of many of the immigrant coun-

<sup>295</sup> In the United States, between 1940 and 1960, the input of the factors of production increased by only 1.7 per cent per decade, whereas output grew by 29 per cent. This large rise in output has been attributed to the increased skill of the labour force, and to advances in technology, organization and management. Besterman, "Immigration as a means ..." (1967), p. 196.

<sup>296</sup> Spengler, "Effects produced in receiving countries ..." (1958), pp. 29-32; Hutchinson, "Immigrant workers in growing industries ..." (1963), pp. 459-460.

<sup>297</sup> For example, an upward mobility of the native work force has been noted in Switzerland, where a relatively large proportion of foreign workers are unskilled, and have found employment in the less well-paid branches of industry, such as building and construction, hotels and restaurants, and agriculture. Bickel, "Foreign workers and economic growth ..." (1967), p. 56. The proportion of foreign workers engaged in low-status jobs has, however, been declining. Mayer, "Post-war migration to Switzerland" (1965), pp. 128-129. Upward occupational mobility and emigration on the part of native workers has been a factor sustaining the need for Irish labour in British industry in the post-war period. Jackson, *The Irish in Britain* (1963), p. 109.

<sup>298</sup> Nixon, "Occupations of immigrants ..." (1959), pp. 656-657.

tries.<sup>299</sup> They have been replaced by the upwardly mobile non-migrant population, whose former jobs have in turn been filled by immigrants from Southern Europe or, in the case of the United Kingdom, by immigrants from the West Indies and other Commonwealth countries, as well as from Ireland. The majority of intra-European migrants from Southern Europe in recent years are from rural areas, but are finding employment in non-rural occupations.<sup>300</sup>

134. Migratory movements in the developing countries display some of the characteristics of the early phase of European migrations. In Africa, there is still a considerable amount of migration between rural areas. In East Africa, such movements have been stimulated by the development of African entrepreneurial farming and the existence of considerable resources of cultivable land.<sup>301</sup> In Ghana, also, migration for rural employment continues to assume much importance; the census of 1960 shows that nearly one half of the foreign-born from other parts of Africa were enumerated as "farmers, fishermen, etc."<sup>302</sup>

135. European and Asian settlers in Africa, though numerically not very significant, have exerted an important influence on the employment structure. European immigrants with their skills and capital were responsible for the development of certain industries, like mining in the southern part of the continent.<sup>303</sup> Indians have assumed an important position in East Africa where they control a large proportion of the trade, employ many natives on sisal and other plantations, and, in Uganda, own most of the cotton ginneries.<sup>304</sup>

136. The labour requirements of industries introduced and developed by Europeans have drawn an extensive migration of Africans from their tribal homes to centres of industrial activity. The proportion of skilled workers to unskilled in these migrations is very low, and the migrant labour system does not provide the native with much opportunity to acquire or develop skills.<sup>305</sup>

137. An early example of occupational specialization was provided by Chinese immigrants to countries of South-East Asia. Partly as a consequence of discrimination, Chinese immigrants went into commerce in large

numbers; they acted as middlemen and frequently served as liaison between Europeans and natives.<sup>306</sup> Chinese capital was an important factor in the development of certain industries in the receiving countries.<sup>307</sup>

138. In the more recent period, international migration in Asia has consisted mainly of refugee movements and post-war repatriations. The shifts of population which followed the partition of India and Pakistan in 1947 created imbalances in the occupational structure of the labour force, since the Moslems were mainly rural handicraftsmen and peasants, whereas the Hindus included a much higher proportion of professional persons, shopkeepers, government employees and clerical workers.<sup>308</sup> Repatriation of the Japanese caused disruptions in the economies of some countries, notably Korea, where the loss of Japanese technical ability had repercussions on development.<sup>309</sup>

139. Even in overpopulated areas of Asia today, it is considered that the diffusion of skills required for development could be stimulated by carefully controlled small immigrations of skilled manpower and qualified personnel.<sup>310</sup>

140. In their attempts to attract skilled workers in order to promote economic development,<sup>311</sup> some Latin American countries (for example, Brazil and Venezuela) seem to have been more successful than others (for example, Argentina) in the post-war period.<sup>312</sup> There is also evidence in Latin America of some movements between neighbouring countries which consist in part of rural peoples who have settled on the land.<sup>313</sup> The large emigration of professional and technically trained personnel from Cuba following the 1958 revolution in that

<sup>311</sup> See, for example, Avila, *Economic Impacts of Immigration* ... (1954), p. 77; and his "Immigration, development and ..." (1961); Beijer, "Scope for Latin America ..." (1965); Mortara, "Population growth and economic difficulties ..." (1962), p. 262.

<sup>312</sup> International Labour Office, *International Migration* ... (1959), pp. 386-388. The shortages of upper level manpower are a particular handicap, since many large-scale industries have installed mechanized, and even automated, plant equipment. See Bouscaren, *International Migrations since 1945* (1963), p. 146.

<sup>313</sup> For example, although statistical information on their numbers are unsatisfactory, there appears to have been a substantial movement of migrants from the rural districts of El Salvador to those of Honduras. Smith, "Migration from one ..." (1959).

country deprived the new régime of badly needed manpower in certain categories of skill.<sup>314</sup>

141. Immigration plays a much less significant role in the economic development of agricultural countries today than it did in the growth of the New World in the nineteenth century.<sup>315</sup> However, the qualitative impact of migration in particular contexts can be considerable.<sup>316</sup> In order to sustain economic growth, the developing countries must ensure a sufficiently rapid growth in the middle and upper levels of manpower relative to the growth of the labour force as a whole.<sup>317</sup> The development of the needed occupational skills can be assisted by migration in several ways: by the temporary emigration of *élites* for training abroad; by short-term immigration of technical experts from developed countries; or by organized programmes for permanent immigration of workers with special skills.<sup>318</sup>

142. Numerous recent studies have been concerned with the fact that in a situation of world-wide shortage of technical and specialized workers, the "pull" of the industrially advanced countries is so strong that qualified workers are being attracted even from the developing countries. This outflow of trained personnel is seen in the very considerable number of scientists and engineers, teachers, doctors and academic persons from developing countries who have taken employment and remained permanently, or for long periods, in the advanced country.<sup>319</sup> Scientists from industrialized countries of Europe have likewise been drawn to the richer countries, particularly the United States, by the promise of greater professional and financial opportunities, but the European countries have been able to offset some of their losses by drawing upon skilled personnel from their former colonies or other developing countries.<sup>320</sup>

<sup>314</sup> MacGaffey and Barnett, *Cuba; Its People, Its Society, Its Culture* (1962), pp. 279, 328.

<sup>315</sup> It has been said that the achievement of rising *per capita* incomes in the less developed countries today depends more on endogenous factors; in so far as it depends on exogenous factors, immigration of labour plays a less important role because of labour-saving processes, the transfer of techniques through equipment, the reduced international flow of capital, and the rapid rates of population increase in the developing countries. Ellis, "Are there preferable alternatives..." (1958), p. 360.

<sup>316</sup> Thomas, *International Migration and Economic Development*... (1961), p. 47.

<sup>317</sup> Besterman, "Immigration as a means..." (1967), p. 196. It has been estimated that these categories must grow two to three times as fast as the total labour force.

<sup>318</sup> See, for example, Pletnev, "Economic development and..." (1967); Thomas, *International Migration and Economic Development*... (1961), p. 43; Silcock, "Migration problems of the Far East" (1958), p. 270.

<sup>319</sup> United Nations, Economic Commission for Europe, "Highly qualified technical manpower..." (1957), p. 63; Thomas, "From the other side..." (1966) and his "Trends in the international migration..." (1961), pp. 16-20; Oteiza, "Emigration of engineers from Argentina..." (1965); Gutiérrez Olivás, "La emigración de recursos humanos..." (1965); Philippines, Bureau of the Census and Statistics, Central Research and Statistical Operation Training Staff, "The 'brain drain' problem in the Philippines" (1967).

<sup>320</sup> Sauvy, "The economic and political consequences..." (1969), p. 53; Beijer, "Brain drain as a burden..." (1969), p. 10.

143. Some controversy has developed over the extent of loss sustained by developing countries as a result of the outflow of trained personnel to more advanced countries. Emphasizing that the benefits of research carried out by the scientists in the country of immigration accrue to all peoples, including those of the country of emigration, Grubel and Scott have argued that only in rather rare circumstances does the outflow of trained personnel adversely affect the welfare of the population of less developed countries.<sup>321</sup> Most writers, however, have stressed the detrimental effects in developing countries resulting from the loss of scarce high-level manpower, and the benefits gained by the country of immigration in acquiring specialists whose educational costs they did not have to bear.<sup>322</sup>

## 2. EFFECTS ON EMPLOYMENT AND UNEMPLOYMENT

144. Because of the common belief that immigration tends to increase unemployment and emigration to reduce it, Governments have imposed limitations on immigration and the employment of immigrants during certain periods, and some Governments have tried to alleviate unemployment by promoting emigration. The timing of migratory movements in relation to business cycles is of much importance, since an influx of immigrant workers during periods of depression would be likely to aggravate the unemployment situation, but empirical studies show that generally the flow of migrants has been greatly curtailed during such periods.<sup>323</sup>

145. The findings of numerous studies suggest that the effects of migration on unemployment are not simple. They are conditioned in part by the fact that the migrants commonly have a distinctive distribution by occupation, industry, and place of residence within the country, so that they are not in full and direct competition with the rest of the labour force. Under some conditions, immigration may reduce unemployment by helping to break bottlenecks due to an insufficient supply of domestic labour in certain occupations or localities, and thus facilitate a general increase in employment.<sup>324</sup> Conversely, the departure of emigrants from particular segments

<sup>321</sup> Grubel and Scott, "The international flow of human capital" (1966), pp. 273-274. See also Johnson, "The economics of the 'brain drain'..." (1965), p. 306.

<sup>322</sup> See, for example, Thomas, "'Modern' migration" (1968), p. 40; Muir, "Should the brain drain be encouraged?..." (1969), pp. 36-37, 47; Patinkin, "A 'nationalist' model" (1968), p. 103.

<sup>323</sup> See, for example, Eckler and Zlotnick, "Immigration and the labor force" (1949), pp. 95-96; Avila, *Economic Impacts of Immigration*... (1954), pp. 50-51; Thomas, "The economic aspect" (1955), p. 171. As noted in section C.2 above, during the depression period of the 1930s in the United States, the number of immigrants coming to seek employment declined more than the number arriving to join relatives.

<sup>324</sup> Isaac, *Economics of Migration* (1947), p. 220. The immigration of refugees to the British Isles in 1933-1938 was found to create employment for British nationals. Walshaw, *Migration to and from*... (1941), p. 93. Through occupational selection of migrants and the direction of displaced persons to specific kinds of employment, Australia was able to ease some of the bottlenecks in her economy after the Second World War. Foxcroft, "Australian migration policy" (1950).

of the labour market may create bottlenecks and increase unemployment.<sup>325</sup>

146. The effect of the arrival of a large number of immigrants on the unemployment level also depends on the volume of investment in productive facilities for their employment, which in turn depends on such factors as the availability of capital, the profits foreseen by prospective investors etc. (see also chapter XIII). In the United States during its period of mass immigration, the immigrants were largely absorbed in industries such as iron and steel and textiles, which were being expanded through heavy investments. This expansion in investment would have been difficult without immigration; on the other hand, when investments lagged, the immigrants tended to replace native workers instead of increasing employment and production.<sup>326</sup>

147. Since migrants are consumers as well as producers, they contribute not only to an increase in the number of job seekers, but also to an increase in the demand for consumer goods and services. Sauvy has, in fact, illustrated some of the principles involved in the argument that a cross-section of immigrants having the same occupational distribution as the general population should not add to unemployment. For example, the physicians and barbers need not fear being displaced by immigrants, since the immigrants will need haircuts and medical care.<sup>327</sup> Writers who have emphasized the role of migrants as consumers have argued that immigration actually tends to reduce unemployment because of the additional employment opportunities likely to be created in response to the immigrants' consumer demands.<sup>328</sup> In fact, if the immigrants have the purchasing power to create effective demand for the many items required for the establishment of their new homes, they may even increase the volume of consumer demand disproportionately.<sup>329</sup> Some time may elapse, however, until the immigrants establish themselves and acquire the needed purchasing power.<sup>330</sup>

148. On the other hand, since migrants typically have a higher proportion of workers than the non-immigrant population, immigration may increase the demand for employment disproportionately to that for consumer goods, thus increasing unemployment. Moreover, the new opportunities for employment created by the arrival

of additional consumers may not be in the same industries and occupations where the immigrants seek employment, resulting in at least some temporary dislocations in the economy.

149. The economic problems of a number of European countries are believed to have been alleviated by emigration during the late nineteenth and early twentieth centuries.<sup>331</sup> This emigration not only improved the employment situation by reducing the labour supply, but it also widened the opportunities for export of consumer goods and investment capital. Much of the unemployment and underemployment which prevailed in Europe during the period between the two world wars was attributed to the slackening of overseas emigration which took place in the 1920s and 1930s.<sup>332</sup> In more recent years, the resumption of overseas emigration contributed to a reduction of unemployment and underemployment in Southern Europe.<sup>333</sup> It has been noted, however, that the improvement in the employment situation has been less in those sectors of the labour force where the surpluses were greatest, namely among agricultural workers and unskilled labourers.<sup>334</sup>

150. The findings of the various studies show that the relationship between immigration and emigration on the one hand, and the levels of employment and unemployment on the other are subject to no simple rules and depend on conditions such as the characteristics of the migrants, the timing of the movement, and various aspects of the economic situation in the countries concerned.

### 3. EFFECTS ON WAGE LEVELS

151. Various authors have been concerned not so much with the possibility that immigration might raise unemployment as with its potential role in lowering wages. A number of studies have considered the theoretical relationships between immigration and wage levels in the receiving countries,<sup>335</sup> and the fear of falling wages has often led labour organizations to favour restrictions on immigration.<sup>336</sup> As in the case of the effects of immigration on unemployment, the relationship between immigration and wages is likely to be complex, since

<sup>331</sup> See, for example, Novitsky and Tolokonsky, "Vliianie emigratsii na usloviia ..." (1929), p. 98.

<sup>332</sup> For example, Boháč, *Mémoire sur le problème démographique* ... (1937), p. 14, advocated a return to free trade and free migration to solve the unemployment problem in Czechoslovakia. See also Skaug, *Memorandum* ... (1937), p. 118.

<sup>333</sup> Kirk, "Major migrations since World War II" (1958), pp. 20-21. Emigration has been urged as a means of combating structural unemployment in Italy. See, for example, Capanna, "Economic problems and reconstruction in Italy: 2" (1951), pp. 31-33; Parenti, "Italy" (1958), pp. 94-95.

<sup>334</sup> International Labour Office, *International Migration* ... (1959), pp. 367, 369.

<sup>335</sup> For a discussion of some of these studies, see Isaac, *Economics of Migration* (1947), pp. 200-209.

<sup>336</sup> Spengler, "Effects produced in receiving countries ..." (1958), p. 42. It has been said that, owing to the influence of trade unions in most industrialized countries, an inflow of foreign labour would not lower wages, but would result in unemployment. Citroen, *Les migrations internationales* ... (1948), pp. 142-143.

<sup>325</sup> During the depression of the 1930s, demands for deportation of alien workers in France were answered by arguments stressing that these workers were engaged in occupations for which the French population could not furnish an adequate supply. Spengler, *France Faces Depopulation* (1938), p. 206; Wlocewski, "Y a-t-il trop de travailleurs ... ?" (1935); Ferenczi, "Contre-migration et politique d'émigration" (1936), pp. 475-476; Mauco, "Alien workers in France" (1936), pp. 186-189.

<sup>326</sup> Timlin, "Economic theory ..." (1950), pp. 213-214.

<sup>327</sup> Sauvy, "Some aspects of ..." (1948), p. 35.

<sup>328</sup> Fromont, for example, advocated liberalization of the immigration law of the United States as a means of increasing investment and employment in that country. Fromont, *Démographie économique* ... (1947), p. 199.

<sup>329</sup> Timlin, *Does Canada Need More People?* (1951), pp. 21-22, 99-109.

<sup>330</sup> Karmel, "The economic effects of immigration" (1953), pp. 85-90.

immigrants, because of their occupational characteristics and settlement patterns, typically compete with only a segment of the native labour force.<sup>337</sup> Very few studies have attempted to isolate the influence of immigration on the wage structure in actual experience. It has been postulated, however, that the decline in real earnings of unskilled labour in the United States between 1900 and 1914 was related to the large volume of immigration of that period.<sup>338</sup>

152. The effect of emigration on wages in the sending country may be more direct than in the receiving country. By reducing the supply of labour in Europe, overseas emigration may account for the more rapid rise in real wages in several countries of Europe than in the United States from 1860 to 1913.<sup>339</sup> The effect of emigration will not necessarily be in the direction of raising wages, however; it may depress wages if the emigrant labour is complementary to non-emigrant labour, just as immigration may help to raise the general wage level if it is complementary to, rather than competitive with, native labour in a rapidly developing country with ample resources.

#### 4. EFFECTS ON THE BALANCE OF PAYMENTS

153. Migration may directly affect the balance of international payments through the funds which the migrants carry with them to the new country and the remittances they send to the home country.<sup>340</sup> According to available statistical evidence, funds brought by immigrants have always been small relative to the amounts brought into countries of immigration in other ways.<sup>341</sup> But immigrants' remittances and funds taken out by returning migrants have in many cases been of great

importance.<sup>342</sup> In seasonal and intracontinental migrations in particular, the migrants typically return a considerable part of their incomes to the country of origin. Exact measurement of the remittances is difficult, but it is estimated that in the early 1960s they amounted to between 1 and 2 per cent of national income in Italy and Spain, 2 and 3 per cent in Portugal, and 3 and 5 per cent in Greece.<sup>343</sup>

154. Where foreign workers constitute a large percentage of the labour force, remittances are said to have sometimes adversely affected the balance of payments for the immigration country. In Ghana, the export of foreign exchange by temporary immigrants created no problems for a time but, with the sharp reduction of foreign exchange reserves by 1963, Ghana limited the allowable remittances of foreign nationals working there.<sup>344</sup> It has been noted that compensation for losses to the immigration countries resulting from remittances may occur, for example, if the immigrants are producing commodities which would otherwise have to be imported.<sup>345</sup> Compensation may also take place if returning migrants create a demand for goods to which they became accustomed while in the immigration country.

#### 5. OTHER ECONOMIC CONSEQUENCES

155. Whether the increase in labour force size resulting from immigration tends to raise productivity and hence contributes to economic growth depends on a number of factors, such as the supply of natural resources and the availability of capital for the absorption of new workers. Some of these aspects are discussed in chapter XIII. The mass immigrations of the past are believed to have stimulated economic development in Australia, New Zealand, Canada, Argentina and Brazil—and in the United

<sup>337</sup> Some authors have discussed the indirect effects on wage levels in occupations not entered by the migrants. See, for example, Isaac, *Economics of Migration* (1947), pp. 203-205; Spengler, "Effects produced in receiving countries . . ." (1958), pp. 19-21.

<sup>338</sup> Douglas, *Real Wages in the United States . . .* (1930), pp. 177-178. In Canada, also, where immigrants furnished cheap labour for manufacturing industries during the early part of the twentieth century, money wages were rising, but perhaps not as rapidly as they might have in the absence of immigration. Corbett, *Canada's Immigration Policy . . .* (1957), p. 132. In São Paulo, where about half of Brazil's immigrants have settled, immigration does not appear to have lowered wage levels. Avila, *Economic Impacts of Immigration . . .* (1954), pp. 89-91. See also his "Brazil" (1958), p. 189. The fear on the part of trade unions that immigrants would deprive native workers of their jobs or lower their living standards by accepting lower rates of pay has not been justified in European countries since the Second World War. Zubrzycki, "Across the frontiers of Europe" (1959), p. 171.

<sup>339</sup> Ellis, "Are there preferable alternatives . . ." (1958), p. 359. See also Phelps-Brown and Hopkins, "The course of wage rates . . ." (1950), p. 236.

<sup>340</sup> United Nations, *Elements of Immigration Policy* (1954), pp. 6, 8.

<sup>341</sup> Isaac, *Economics of Migration* (1947), pp. 233-240. However, Fromont in *Démographie économique . . .* (1947), p. 195, cites statistics showing rather considerable amounts of capital carried by German emigrants. Thomas in *Migration and Economic Growth . . .* (1954), p. 220, refers to the adverse effect on the balance of payments experienced by Britain as a result of capital taken out by emigrants after the Second World War.

<sup>342</sup> For example, Harkness mentioned the large sums of money that Irish emigrants sent home following periods of heavy emigration. Harkness, "Irish emigration" (1931), pp. 269-270. Parenti's analysis for Italy for the period 1861-1940 indicates that remittances accounted for as much as 4.7 per cent of national income during 1901-1910. The author concludes that remittances were an important and perhaps the decisive factor in the economic leap forward which Italy experienced in that decade. Parenti, "The role of emigrants' remittances . . ." (1967). One estimate of the average annual cash remittances of overseas Chinese for twenty or thirty years before the outbreak of the Sino-Japanese War reaches an amount far exceeding the country's unfavourable trade balance. Lasker, *Asia on the Move . . .* (1945), p. 83. As a result of remittances, families of persons who had emigrated from China were economically much better off than non-emigrant families. Chen, *Emigrant Communities in South China . . .* (1940), pp. 87-88. Because emigrants represented only a minute fraction of India's population, the effect of remittances has been rather modest. See Sundaram, "Effects of emigration . . ." (1955), pp. 234-238; Jennings, *The Economy of Ceylon* (1951), pp. 44-45. For other estimates of monetary transfers made in connexion with certain migratory movements, see Citroen, *Les migrations internationales . . .* (1948), pp. 97-98; Isaac, *Economics of Migration* (1947), pp. 244-247; Weber, "The employment of aliens in Germany" (1965), p. 37.

<sup>343</sup> Parenti, "The role of emigrants' remittances . . ." (1967), p. 222.

<sup>344</sup> Gil, "Immigration into Ghana . . ." (1967), p. 205. See also Caldwell, "Migration and urbanization" (1967), pp. 120-121. On effects of remittances in Switzerland and Ceylon, see, respectively, Bickel, "Foreign workers and economic growth . . ." (1967); Hague, "Summary record of the debate" (1958), p. 442.

<sup>345</sup> Bourgeois-Pichat, "Migrations et balance des comptes" (1949).

States until late in the nineteenth century—by bringing into being a better combination of the factors of production and releasing the forces of increasing return.<sup>346</sup>

156. On the other hand, in certain situations emigration is believed to be desirable as a means of raising productivity, for example, in the case of densely populated agricultural countries such as Haiti and Mauritius, and in Greece and Italy where large rural populations are employed at a low level of productivity on relatively small areas of cultivable land.<sup>347</sup> Even in some highly industrialized countries like the Netherlands, emigration has been considered advantageous at certain periods, because of a fairly rapid rate of population growth and a shortage of raw materials.<sup>348</sup>

157. Since migration is usually selective with respect to sex and age characteristics, its effect on the structure as well as the size of population has a bearing on its economic benefits or disadvantages. In those instances where immigration has been on a sufficiently large scale to significantly increase the ratio of workers to dependants, the effect may be economically advantageous to the receiving country provided that other conditions are favourable. The progressive ageing of France's population was offered as an argument for admitting large numbers of immigrants in ages 26 to 35 years after the Second World War, since such an immigration would distribute the dependency burden among a larger number of productive adults.<sup>349</sup> The effect of migration on the population's sex and age structure has been considered of such importance that even in some situations where a reduction in total population size might be considered beneficial from the economic point of view, it is argued that emigration would be undesirable because of the likely disproportionate loss of young adults.<sup>350</sup>

158. Immigration flows which bring in a relatively high proportion of young adult workers are considered advantageous for the receiving countries for other reasons. It is said that the country of immigration derives the benefit, in the form of productive labour, from the investment which the sending country has made in the maintenance

<sup>346</sup> Spengler, "Effects produced in receiving countries . . ." (1958), pp. 38-41.

and education of these persons during their youth.<sup>351</sup> For example, it has been maintained that the United States was spared the cost of raising to manhood a large fraction of its labour force, and that this cost, borne by the countries of emigration in Europe, represents a great contribution of Europe to the wealth of America.<sup>352</sup>

## 6. ECONOMIC EFFECTS OF SELECTED POST-WAR MIGRATIONS

### (a) *More developed countries*

159. Some studies have examined the effects of migrations occurring in the post-war period on various aspects of the economies of the countries involved. The initial mass immigration into Israel was accompanied by much unemployment, but with heavy government outlays and massive assistance from abroad, only 3 per cent of the civilian labour force remained unemployed by 1963. Immigration has continued to exert strong inflationary pressures, however, particularly since the more recent migrants have a larger average family size and relatively lower levels of skills and productive efficiency, as compared with earlier immigrants. Absorption of the immigrants was possible only because the whole national economy was organized towards this end, and because of the very large transfers of capital from abroad.<sup>353</sup>

160. Though in no other country were the pressures from immigration so severe, or the assistance from abroad so large, some of the same economic features have appeared elsewhere. There were strong inflationary trends in the Australian economy in the late 1940s, arising from the release of demands for goods and services which had been restricted during the war, and refugee immigration into Australia at this time would have greatly intensified these inflationary pressures had it not been for the adoption of policies which directed the immigrants into basic industries where labour shortages existed, and the postponement of large investments in housing by accommodating the immigrants temporarily in old army camps and other wartime buildings. Immigration continued to be favoured by the Government after 1950, and indigenous capital formation, investments from overseas and a favourable balance of payments were adequate to sustain a population growth rate which approximated 2 per

<sup>351</sup> United Nations, *Elements of Immigration Policy* (1954), p. 6; Singer, "The distribution of gains . . ." (1950), p. 483.

<sup>352</sup> Gini, "Apparent and real causes . . ." (1948), pp. 356-361; Vita, "Der kapitalisierte . . ." (1940). Some attempts have been made to estimate the costs of rearing a child to adulthood, but much of the benefit to be derived by the country of immigration depends on the kind of education and training the migrant received, and its relevance to the work he performs in the new country. Isaac, *Economics of Migration* (1947), p. 229. For estimates of the monetary value of human capital that Brazil has obtained through immigration, see Avila, *Economic Impacts of Immigration . . .* (1954), p. 61. See also Mortara, *O custo de produção do homem adulto . . .* (1946), p. 118. It has been estimated that the cost to the United Kingdom of educating and training an emigrant is from £500 to £1,000. Plant, *Overseas Settlement . . .* (1951), p. 3. Clough has calculated the loss to Italy resulting from emigration. Clough, *The Economic History of Modern Italy* (1964), pp. 139-140.

<sup>353</sup> Sicron, "The economics of immigration . . ." (1967). See also International Labour Office, *International Migration . . .* (1959), pp. 85-90.

cent annually, without eroding *per capita* real income. Problems arising from the high demand for non-productive investment—for example, in housing, schools, and public works—which resulted from the emphasis on family immigration, have been contained, perhaps partly because of investment lags, and partly by the careful recruitment of immigrant workers of high productive efficiency possessing skills most needed in the Australian economy.<sup>354</sup>

161. Immigration into Canada in the post-war period, though less planned, appears to have had broadly similar economic consequences. It has augmented the labour supply at a time when its increase was lagging, has supplied new skills, and has been one factor in the marked rise in over-all productivity since 1945. It has been said that "Canada affords a typical example of an economy of rapidly increasing returns, in which there are sufficient material resources and capital available to enable the productivity of labour to increase rapidly; thus the entry of additional workers into the labour force cannot but have made a direct contribution to this trend".<sup>355</sup> While immigration cannot be considered the cause of the post-war investment boom, it may have been indispensable to its realization.<sup>356</sup>

162. Intracontinental migration within Europe in the post-war period has been largely regulated by means of employment permits which authorize foreigners to work for a stated period in certain occupations in which the demand for labour cannot be satisfied in the domestic labour market. Various agreements have been worked out to promote the flow of labour from areas in which it was redundant to areas in which it was in short supply.<sup>357</sup> The rapid rate of economic growth in Western Europe since 1953 permitted the absorption of an increased number of immigrants. This period has been marked by an increase in commodity trade which has brought raw materials into European industrialized countries cheaply enough and in quantities sufficient to enable the manufactured goods to compete on world markets and the industries of these countries to absorb enough immigrant labour to increase their work forces, or to replace labour which had emigrated.<sup>358</sup> The countries of Northern and Western Europe have been able to sustain investment levels high enough to attract immigrants who have gone in greatest numbers into areas where the expansion of the indigenous work force was lowest, owing to demographic factors. The large inflow of foreign workers to Switzerland undoubtedly contributed to an acceleration of that country's economic growth during the 1950s, but the

appearance of inflationary effects on the price level, and other economic disadvantages, led to restrictions on admissions of foreign workers in 1963.<sup>359</sup> At the same time, emigration from Southern European countries has contributed to more effective resource allocation by holding down the labour supply, which might otherwise have exceeded the absorptive capacity of the economy.<sup>360</sup> But the exodus from some of these countries may have reached proportions by the 1960s where it was draining them of manpower essential to their development.<sup>361</sup> In Ireland, too, continued net emigration was considered to have a dampening effect on economic activity.<sup>362</sup>

#### (b) *Less developed countries*

163. In Africa, the migration system, which has furnished employers with the main source of labour supply, has been said to perpetuate the low wage structure, particularly since the worker's family has an alternative means of support in agriculture.<sup>363</sup> There are differences of opinion regarding the efficiency of the system from the point of view of the employer and the economy generally.<sup>364</sup> Some writers have emphasized the instability of the system, whereby the numbers seeking work may vary from year to year, labour turnover is high, and productivity low. Moreover, travel over long distances has had adverse effects on the health of workers.<sup>365</sup> On the other hand, a more favourable view is taken by some writers. It is said that, by creating easy labour supply conditions, the migration system has permitted West Africa to enjoy greater economic growth than otherwise would have been possible. Furthermore, there is an advantageous seasonal

<sup>359</sup> Bickel, "Foreign workers and economic growth ..." (1967), pp. 55-56; United Nations, Economic Commission for Europe, *Economic Survey of Europe in 1964* ... (1965), chap. 2, pp. 35-36.

<sup>360</sup> Kindleberger, "Emigration and economic growth" (1965), p. 253.

<sup>361</sup> Triantis believed that the high rate of emigration experienced by Greece in 1962 and 1963 might be detrimental if continued. Triantis, "Population, emigration and economic development" (1967), p. 247. Emigration from Greece had further accelerated by 1965, and Zolotas cited resultant labour shortages in both the agricultural and non-agricultural sectors which were holding back Greek economic development. Zolotas, *International Labor Migration* ... (1966), pp. 47-51. See also Papelasis, "Les problèmes de la main-d'œuvre de la Grèce ..." (1963), pp. 318-319; Parenti, "Italy" (1958), pp. 94-95. Parenti noted that emigration had made a definite contribution to the country's economic development, except in cases where an excessive outflow created problems in key sectors of the economy.

<sup>362</sup> United Nations, *Economic Planning in Europe* (1965), chap. 2, p. 7; Batten, *Problems of African Development* (1960), part 1, p. 96; more employment opportunities in industry to help reduce emigration and overcome a period of economic stagnation.

<sup>363</sup> United Nations, *Review of Economic Conditions in Africa* (1951), p. 12; Orde Browne, *Labour Conditions in East Africa* (1946), p. 7; Batten, *Problems of African Development* (1960), part 1, p. 96; International Labour Office, *African Labour Survey* (1958), p. 138.

<sup>364</sup> See, for example, Hailey, *An African Survey* ... (1957), pp. 1277-1278.

<sup>365</sup> Some of these unfavourable aspects are noted in International Labour Office, *African Labour Survey* (1958), p. 137; ———, "Inter-territorial migrations ..." (1957), pp. 307-310; Bovill, "Native labour" (1950), pp. 32-33; Orde Browne, *Labour Conditions in East Africa* (1946), pp. 6, 15, 17-18, 24; International Labour Office, "Interracial wage structure in certain parts of Africa" (1958), pp. 48-49; Batten, *Problems of African Development* (1960), part 1, pp. 96, 99-101.

<sup>355</sup> International Labour Office, *International Migration* ... (1959), pp. 384-385.

<sup>356</sup> Corbett, *Canada's Immigration Policy* ... (1957), p. 170. See also Timlin, "Canada" (1958), p. 159.

<sup>357</sup> International Labour Office, *International Migration* ... (1959), pp. 214-217; Organisation for Economic Co-operation and Development, *International Joint Seminar on the Adaptation* ... (1965), pp. 51, 60-61.

<sup>358</sup> Thomas, *International Migration and Economic Development* ... (1961), pp. 36-41.

dovetailing, whereby the periods of peak wage labour demand for agricultural export crops coincides with the dry season when the need for men to participate in the cultivation of traditional crops in the villages is at a minimum.<sup>366</sup>

164. Also controversial are the effects of the outflow of migrants on the economies of the tribal village. In many studies it has been maintained that the problem of raising sufficient food to support the population has been aggravated by out-migration, and that the dependency burden of those who do not migrate has been increased.<sup>367</sup> The findings of other studies suggest that, while the villagers have found it necessary to make certain adjustments to compensate for the absent men, the production of traditional crops has not suffered greatly.<sup>368</sup>

165. Owing to the relatively small size of many African nations, efficient use of manpower there may require movements across international boundaries. In Asia, on the other hand, movements motivated by similar economic forces are likely to take place mostly within the great land masses of nations, and thus constitute internal, rather than international, migration. As noted earlier, the principal large-scale migrations in Asia following the Second World War were associated with political events. The absorption of refugees after the partition of India and Pakistan is said to have required the investment of large sums which otherwise could have been invested in the development of the economy.<sup>369</sup>

166. In Latin America, immigration policy, which has traditionally favoured the settlement of immigrants on the land,<sup>370</sup> has presented many problems. Although

large-scale, well-subsidized group settlements have often met with considerable success, while at the same time transmitting their more advanced farming methods to the local population,<sup>371</sup> the isolated immigrant farmer has tended, rather, to adopt the wasteful methods of cultivation characteristic of the region.<sup>372</sup> Moreover, some immigrants admitted for work in agriculture have later migrated to urban areas where they have sought employment in the already saturated tertiary sector of the labour market.<sup>373</sup>

167. Early immigration to Latin America was accompanied by the transfer of sizable amounts of capital—either brought by the immigrants directly or introduced by European investors<sup>374</sup>—which permitted the establishment of many economic enterprises. In more recent years, both European investment and immigration to Latin America have been considerably reduced,<sup>375</sup> and the high rates of return migration<sup>376</sup> partly reflect this lack of sustained and expanding investment to absorb the immigrants.

## E. Social aspects of migration

168. Migration has not been viewed solely in economic terms as the movement of producers and consumers. Much attention has also been given to problems associated with the integration of migrants into the social fabric of the receiving country. Immigrants bring with them their customs, language, religion and political ideas, and are constantly faced with many problems of adjustment to their new environment. This complex process of adjustment has been examined in many studies in recent years, although there has been little attempt at systematic and comparative analysis.<sup>377</sup>

### 1. SOCIAL GOALS OF IMMIGRATION

169. Some writings have been concerned with the proper social goals of immigration: how much cultural diversity should be encouraged, and whether the aim should be to “assimilate” or “integrate” the migrant into

<sup>366</sup> Berg, “The economics of the migrant labor system” (1965), pp. 161-164. See also Skinner, “Labor migration among the Mossi . . .” (1965), pp. 67-70.

<sup>367</sup> Food and Agriculture Organization of the United Nations, *FAO Africa Survey* . . . (1962), p. 18; International Labour Office, “Interracial wage structure . . .” (1958), pp. 48-49; Hailey, *An African Survey* . . . (1957), pp. 1386-1387; Batten, *Problems of African Development* (1960), part 1, p. 33.

<sup>368</sup> Despite the absence of over 40 per cent of adult males, there appeared to be no ill effect on food production among the Esu people of Cameroon (the British Cameroons). Ardener and Ardener, “Migration among two Southern Cameroon tribes . . .” (1960), pp. 217, 227. Subsistence production appeared to be little affected in certain districts of Northern Nigeria where more than a third of the men were absent. Prothero, “Migratory labour from north-western Nigeria” (1957), pp. 255-260. Berg, in “The economics of the migrant labor system” (1965), p. 171, called attention to the existence of co-operative work groups in the villages which helped to keep production from falling. Skinner found no clear evidence that the seasonal migration of men adversely affected the production of basic food crops. Skinner, “Labor migration among the Mossi . . .” (1965), p. 70. See also his “Labour migration and its relationship . . .” (1960), p. 383.

<sup>369</sup> International Labour Office, *International Migration* . . . (1959), pp. 116-120. According to Brahmananda, this migration reduced the average level of earnings in overcrowded occupations in India, and increased inflationary pressures. Brahmananda, “The impact on India . . .” (1958), pp. 290-291.

<sup>370</sup> The need to settle and develop the hinterlands has been much emphasized, but the predominance of large estates in the agricultural organization was not conducive to attracting independent proprietors. See, for example, Smith, *Brazil* . . . (1963), pp. 119-120; Dickmann, *Población e inmigración* (1946), pp. 62-64; Shellenberger, “Argentina’s agricultural future” (1945); Avila, *Economic Impacts of Immigration* . . . (1954), p. 80.

<sup>371</sup> In Mexico, for example, colonies founded by American Mormons and German-Canadian Mennonites, using superior agricultural techniques, serve as demonstration projects to peasants in the vicinity. Whetten, *Rural Mexico* (1948), pp. 158-164. Similarly, the Dutch agricultural settlement of Holambra in Brazil, and the Pedrinhas settlement of Italians, also in Brazil, have disseminated advanced techniques brought from Europe. Besterman, “Immigration as a means . . .” (1967), p. 197. The settlement at Turén, Venezuela, where immigrants were carefully selected and given substantial financial assistance from the Government achieved a much higher standard of production than did other settlements in Venezuela which were not similarly planned and assisted. Unión Panamericana, *Las inmigraciones en Venezuela* . . . (1956), pp. 85-112; Zañartu, “Immigration and development” (1963), pp. 98-99.

<sup>372</sup> Pan American Union, *Immigration in Latin America* (1964), p. 104.

<sup>373</sup> Bouscaren, “Italy’s role in international migration” (1962), p. 84; Zañartu, “Immigration and development” (1963), p. 98.

<sup>374</sup> See, for example, United Nations, Economic Commission for Latin America, *Immigration in Chile* (1950), p. 83.

<sup>375</sup> Thomas, *International Migration and Economic Development* . . . (1961), p. 44.

<sup>376</sup> See Neiva, “International migrations . . .” (1965), p. 128.

<sup>377</sup> Eisenstadt, “Analysis of patterns . . .” (1953), p. 167.

his new society. The predominant view is that the concept of "integration" is to be preferred, since it implies a two-way process, whereby the immigrant is changed by his association with the native group, but he in turn has an impact on the community.<sup>378</sup> Thus, emphasis is placed on the desirability of cultural pluralism within a framework of social unity, a process involving adjustment of the immigrants toward uniformity in certain areas, while preserving cultural differences in others.<sup>379</sup>

170. A UNESCO conference of migration experts, meeting in 1955 to consider the impact of immigration on different spheres of society, concluded that immigrants have generally not fundamentally altered the existing social organization and patterns, though they have contributed to the cultural enrichment of their new society.<sup>380</sup> In such important immigration countries as Australia, Canada and the United States, certain writers have emphasized the economic contributions of migrants, while giving less importance to their role in instituting social change.<sup>381</sup> Immigrants to Brazil are said to have had an important influence on economic development and cultural life, without having much effect on political, organizational and structural patterns.<sup>382</sup> On the other hand, immigration into Argentina, which was on a large scale relative to the size of the native population, played a major role in the modernization of the country and the transformation of its social structure.<sup>383</sup>

## 2. SOCIAL ABSORPTIVE CAPACITY

171. Cultural factors may determine the desirable upper limits of immigration, since it might happen that a country could absorb a larger number of immigrants in purely economic terms, but not without threatening the "community core", that is, the political, cultural and social factors which have come to dominate the life of a nation. The core may permit a considerable degree of ethnic or cultural diversity, and be changed by this, but when it is felt that the rate of change is beyond the core's power of absorption or tolerance, protective measures are invariably taken in the form of restrictive immigration policies.<sup>384</sup> The core thesis implies that immigrant cultures

will remain minority cultures, and the pressures of the majority will exert a strong influence on immigrants—and particularly the descendants of immigrants—to conform.

172. After the First World War, the point was reached in the United States where it was feared that a further large-scale immigration from Southern and Eastern Europe would have undermined the nation's core,<sup>385</sup> and this fear led to restrictive legislation. Concern has recently been felt in Switzerland that immigration was endangering that country's national identity as well as its social, political and religious internal balances.<sup>386</sup>

173. The problems of assimilation in Israel were unique in that they were not those of merging new cultures with an established one, but rather of building a new nation out of diverse elements; these elements, however, had common bonds in their religion, belief in Zionist ideals, and for many, previous persecution.<sup>387</sup>

## 3. FACTORS AFFECTING INTEGRATION

174. The success or failure of the integration process depends on a number of factors, including the attitude and actions of the Government of the country to which the migrant goes, and of the people among whom he lives, as well as the attitudes and culture of the immigrant group itself.<sup>388</sup> In the immigrant country, a social structure which is not too rigid, and which affords immigrants equal opportunities with natives, is an aid to rapid integration. The opportunities afforded to immigrants in nineteenth-century North America to climb the social ladder on a basis of near equality with non-immigrants facilitated integration.<sup>389</sup> The absence of rigid social stratification and racial and religious prejudices has been cited as a factor in the smooth assimilation of immigrants in Brazil.<sup>390</sup> Immigrant groups have varied in their degree of assimilability. Great differences in language, religion, physical appearance, social customs and cultural tradition

<sup>378</sup> Thomas, *International Migration and Economic Development* . . . (1961), pp. 51-53. For examples of the influence of immigrants on the culture of the receiving population, see Price, *Southern Europeans in Australia* (1963), p. 203, and Gini, "Le problème de l'assimilation" (1955), p. 39.

<sup>379</sup> Borrie, *The Cultural Integration of Immigrants* . . . (1959), p. 94. See also Kiser, "Cultural pluralism" (1949), p. 129.

<sup>380</sup> Handlin, "Conclusion" (1955), p. 189.

<sup>381</sup> Handlin and Handlin, "The United States" (1955); Borrie, "Australia" (1955), pp. 113-114; Jones, "Some social consequences . . ." (1967). Other authors have given a greater emphasis to the long-term effects of cultural and ethnic diversity. See, for example, Price, *Southern Europeans in Australia* (1963), p. 295.

<sup>382</sup> Willems, "Brazil" (1955), pp. 145-146.

<sup>383</sup> Germani, *Política y sociedad en una época de transición* . . . (1962), chap. 7; and his *Mass Immigration and Modernization in Argentina* (1966). According to the latter work (p. 166), about 6.5 million foreigners entered Argentina between 1856 and 1930, whereas the local population was estimated at only 1.2 million in 1856.

<sup>384</sup> Borrie, *The Cultural Integration of Immigrants* . . . (1959), pp. 114-115.

<sup>385</sup> *Ibid.*

<sup>386</sup> Kindlerberger, "Emigration and economic growth" (1965), p. 253. At times, further immigration into France has been seen as a threat to French culture. Nourissier and Pillépich, *Enracinement des immigrés* (1951), pp. 15-16. In applying a concept of social absorptive capacity, the Canadian Government has sought to determine how many immigrants Canada can absorb without dislocating the society in terms of religious and ethnic composition, family and social class structure, political organization and ideology. Jones, "Some social consequences . . ." (1967), p. 208. See also Timlin, "Canada" (1958), p. 150.

<sup>387</sup> For studies of the assimilation and adaptation processes in Israel, see, for example, Eisenstadt, *The Absorption of Immigrants: A Comparative Study* . . . (1954); UNESCO, "Cultural assimilation and . . ." (1956); Eisenstadt, "Sociological aspects of the economic adaptation . . ." (1956); and his "Israel: traditional and modern . . ." (1956); Bachi, "Immigration into Israel" (1958), pp. 334-341.

<sup>388</sup> Bunle, "The cultural assimilation of immigrants" (1950).

<sup>389</sup> Mauco, "The assimilation of foreigners in France" (1950), pp. 15-16; Handlin and Handlin, "The United States" (1955), p. 23.

<sup>390</sup> Neiva and Diégues, "The cultural assimilation . . ." (1959), p. 185.

are likely to impede integration.<sup>391</sup> For example, such differences have generally set Chinese and Indian immigrant communities apart from the populations of the countries in which they have settled, making these groups somewhat resistant to assimilation.<sup>392</sup>

175. Economic absorption of the immigrants has often been referred to as a prerequisite for cultural integration, though the latter does not automatically follow from the former.<sup>393</sup> Moreover, acceptance of the immigrants by the local community is sometimes impeded by the types of economic activity which they pursue.<sup>394</sup> In order to avoid competition for employment between immigrants and the native population in post-war Australia, migrants were carefully selected for industries where there was an acute labour shortage. There was similarly careful planning in the encouragement of particular classes of immigrants to Canada, and the selection of immigrants for rural settlement in Venezuela.<sup>395</sup>

176. While immigration of the family unit is held to be a desirable goal, it is not certain that such migration is an aid to cultural integration. The immigrant family may bring with them patterns of family relationships which differ considerably from those in the country of settlement, and while integration in the new community on an economic level may be relatively easy, integration at the social and cultural level may be long delayed.<sup>396</sup>

<sup>391</sup> The role of religion in contributing to the persistence of cultural values incompatible with complete integration is especially great where the immigrant community is large enough to have its own church where services are conducted in the mother tongue of the immigrants. Zubrzycki, "Across the frontiers of Europe" (1959), p. 178. The Irish immigrants in Boston were set apart by religion and culture from the local community, and as a result their assimilation lagged behind that of other immigrants. Handlin, *Boston's Immigrants, 1790-1865* ... (1941), chap. 5.

<sup>392</sup> See, for example, Davis, *The Population of India and Pakistan* (1951), p. 104; Berry, *Race and Ethnic Relations* (1958), pp. 208-210; Thompson and Adloff, *Minority Problems in Southeast Asia* (1955), pp. 9, 64.

<sup>393</sup> Borrie, *The Cultural Integration of Immigrants* ... (1959), pp. 101-102. The Germans who settled in South Australia in the nineteenth century and the Japanese immigrants to Brazil in the twentieth century are examples of groups which remained culturally isolated, though economically absorbed. Borrie, *Italians and Germans in Australia* (1954), pp. 217-218. Smith, *Brazil* ... (1963), pp. 130, 316-317.

<sup>394</sup> The hostility towards Chinese and Indian migrants in South-East Asia has been closely related to their economic functions, whether it be the wage-depressing competition of coolie labour, the shrewd business practices of merchants or bankers, or the monopolistic control over vital industries. See, for example, Pillai, *Labour in South-East Asia* ... (1947), pp. 123-128; Lasker, *Peoples of Southeast Asia* (1944), pp. 133-137; Cator, *The Economic Position* ... (1936), pp. 63-67, 115; Jacoby, *Agrarian Unrest in Southeast Asia* (1961), pp. 21, 24, 39, 152; Landon, *The Chinese in Thailand* (1941), p. 130. Little objection has been raised to Japanese immigrants in Brazil, who are mostly occupied on plantations and farms, but there has been considerable resentment against the same ethnic group in Peru, where the majority are engaged in commerce. Bradley, *Trans-Pacific Relations* ... (1942), pp. 57-60.

<sup>395</sup> Borrie, *The Cultural Integration of Immigrants* ... (1959), pp. 104-105.

<sup>396</sup> Borrie, *The Cultural Integration of Immigrants* ... (1959), pp. 124-125. Some problems of adjustment encountered by pre-1946 immigrants in Canada were related to the hierarchical family structure which was typical of the rural areas of their native countries. Jones, "Some social consequences ..." (1967), p. 208. The autocratic position of the father in immigrant families from some

177. The facility with which integration takes place also seems to be related to the settlement pattern of immigrants. Adjustment appears to proceed most rapidly when the immigrant has numerous relationships with members of the non-migrant community, while not being cut off entirely from his own ethnic group.<sup>397</sup> Thus, an urban setting is more likely to be conducive to integration than a rural one. In Australia, the ready assimilation of Scandinavian immigrants, in contrast with the Germans, is believed to be partly due to the geographic dispersion of the former, and their economic absorption into a wide range of occupations.<sup>398</sup>

178. Granting to immigrant workers and their families equal access to the social services and benefits enjoyed by natives is an effective means of facilitating adjustment and protecting immigrants from various hazards which lead to indigence and dependency.<sup>399</sup> Other factors of importance include the opportunity for occupational advancement and the freedom to change occupations.<sup>400</sup>

#### 4. SOCIAL PROBLEMS ARISING FROM MIGRATION

179. The frustrations which immigrants experience cause some to reject the new society and engage in crime or other forms of anti-social behaviour, the moral controls of the previous environment having been weakened. In many cases, however, cultural values carried over from the native country are sufficiently strong to sustain the immigrants themselves, and the manifestations of conflict resulting in cultural disintegration and crime appear with greater intensity in the second generation. The children are pulled in two directions; what is learned at school and outside the home is often in conflict with what is learned within the family circle. There is a consequent tendency for this generation to be less law-abiding than their parents.<sup>401</sup>

parts of the Middle East often led to severe conflicts in Israel, where the predominant pattern encourages uninhibited development of children. Isaac, "Israel—a new melting pot?" (1959), p. 250. The low incidence of family migration in said to have contributed to the rapid assimilation of Scandinavians in Australia. Borrie, "Australia" (1955), p. 95. On the other hand, some authors have considered that assimilation has been handicapped when immigrants have included a high proportion of workers without their families. Langrod, "Social problems of absorption ..." (1958), p. 307.

<sup>397</sup> Petersen, *Planned Migration* ... (1955), pp. 184-185. The long retention of certain aspects of Old World culture among the German immigrants in Brazil is believed to be due to their secluded areas of settlement from the outset. On the other hand, the placement of Italian immigrants in the coffee plantations of São Paulo where they had daily contacts with Brazilians stimulated assimilation. Neiva and Diégués, "The cultural assimilation ..." (1959), p. 217. See also Willems, "Brazil" (1955), pp. 122, 134.

<sup>398</sup> Borrie, "Australia" (1955), pp. 94-95.

<sup>399</sup> The equality given to refugees under Britain's social assistance and insurance scheme in the post-war period was an important factor in their successful resettlement. Bülbring and Nagy, "The receiving community in Great Britain" (1955), p. 122.

<sup>400</sup> Zubrzycki, "Across the frontiers of Europe" (1959), p. 168. The refugee population in post-war Austria made great progress toward integration, once restrictions against their employment outside agriculture were lifted. International Labour Office, *International Migration* ... (1959), p. 55; see also pp. 405-408.

<sup>401</sup> MacIver, *The Web of Government* (1947), pp. 77-78; Woolston, "The process of assimilation" (1945), p. 419.

180. Mental disorders are another frequent product of the severe strains to which individual immigrants are sometimes subjected. Suicide and mental hospitalization rates have been found to be higher among immigrants than among the native population,<sup>402</sup> and such evidence as is available suggests that, among refugee groups, rates of mental breakdown are considerably higher than among other migrants.<sup>403</sup> A study of Polish immigrants in Britain suggested a relationship between discrimination in employment and the incidence of mental disorders.<sup>404</sup> In France, a study of Poles who were detained for criminality or mental deficiency showed that the individuals concerned were predominantly agricultural labourers who had been sent to work on isolated farms in conditions which gave them almost no opportunities for contact with other human beings.<sup>405</sup>

181. In Africa, serious social problems have been associated with detribalization resulting from the migration of agricultural workers from a highly regulated tribal life to the freedom of the urban environment where they seek paid employment in industry, mining and commerce.<sup>406</sup> The greater the distance of the migration,

the greater is the likelihood that international boundaries will be crossed and that changes in language, climate and diet will call for adjustment on the migrant's part. In these circumstances, it is not likely that the migrant's former values, his religious beliefs and loyalty to the tribal chief will remain intact, and he is apt to take on new material values.<sup>407</sup> Since the migrants are largely males, a severe strain on the institution of marriage and family organization results.<sup>408</sup> Tensions have risen in the urban areas where there has been a large influx of migrants. There have been serious shortages of suitable housing, resulting in the growth of "squatters' camps" and "shanty towns",<sup>409</sup> and the large preponderance of males has led to prostitution and venereal disease.<sup>410</sup> An increasing tendency for women to leave the tribal community, either for employment or to join their husbands, has been noted, and this is a factor operating to loosen the ties of men with their tribes, and to transform shifting labour migrants into long-term or permanent urban dwellers.<sup>411</sup>

## SEX AND AGE STRUCTURE

1. The sex and age structure of a population has many important implications, the most fundamental being to define the limits of the society's reproductive potential. This structure is also the basic demographic determinant of a nation's manpower supply and it influences requirements for various essential goods and services. The incidence of school attendance and economic activity and of such events as household formation varies markedly at different ages. Therefore, fluctuations in the numbers of persons attaining particular ages can have significant repercussions—for example, in producing short-term pressures on schools, employment opportunities, and needs for new housing units.

2. The sex-age structure of a population at any time is the result of past trends in fertility, mortality and migration. It, in turn, influences the current levels of crude vital rates and the rate of population growth, since births, deaths and migration occur with unequal frequency at different ages. Because of its significant demographic, economic and social implications, the dynamics of a population's sex and age structure constitutes a central subject in demographic analysis.

3. This chapter presents, in section A, an analysis of current sex and age patterns in different regions of the world and changes in these patterns over time. Section B is concerned with the factors determining sex and age structure and section C with the effects of sex and age structure on other demographic variables. In section D, some of the social and economic implications of a population's sex and age composition are examined.

## A. Patterns of sex and age structure

## 1. SEX STRUCTURE

4. The sex composition of a population is the most basic of all demographic characteristics and it affects directly the incidence of births, deaths and marriages. Migration rates, occupational structure and virtually all other population characteristics may be influenced by the ratio between the sexes. Sex structure is conveniently described by a series of "sex ratios" at various ages, most commonly by the number of males per 100 females in the same age group (the "masculinity ratio").<sup>1</sup> This ratio at birth is most commonly around 105 in countries having reasonably good statistics, and varies

only within a fairly narrow range from country to country, and within a given country from year to year (see section B). However, since age-specific mortality rates are usually greater among males than among females at every age,<sup>2</sup> this ratio tends to be gradually reduced with age, eventually falling below 100. The age at which equality between the number of males and females is attained depends upon the particular schedule of mortality.<sup>3</sup> Beyond this age, the number of females begins to exceed the number of males, and the excess grows larger with advancing age. Deviations from the pattern described above, when they occur, are usually caused by atypical patterns of mortality or large-scale selective migration. Some examples of such deviations are discussed further on.

5. Table VIII.1 presents masculinity ratios for three broad age groups and the total population, for regions of the world in 1965.<sup>4</sup> It is seen that, as expected, the sex ratio generally decreases with increasing age. Such a pattern is observed in all regions of Europe, in Latin America, Northern America and the Soviet Union, as well as in parts of Africa and Asia. In Australia and New Zealand, the high masculinity ratio at ages 15-64 years is probably due in great part to the consistently higher percentage of males among the migrants to those countries (see chapter VII, section C).<sup>5</sup> This immigration has in turn contributed to the male deficit in the countries from which the immigrants have been drawn.

6. In contrast with prevailing patterns, unusually high sex ratios are found in Middle South Asia, and at ages 15-64 years the sex ratio is higher than for the group under 15 years. These deviations are believed to be due primarily to the fact that in several countries of this region, namely Ceylon, India and Pakistan, female mortality appears to exceed that of males during childhood and the reproductive period.<sup>6</sup>

<sup>2</sup> Available data for a number of developing countries show higher mortality for females than for males, particularly in the child-bearing ages (see chapter V, section B).

<sup>3</sup> In the United States of America, for example, it is found to be around the age of fifty, based on 1950 mortality rates. Stern, *Principles of Human Genetics* (1960), pp. 427-428.

<sup>4</sup> For a discussion of variations in sex ratios in selected countries, see Desai, *Size and Sex Composition of Population ...* (1969), pp. 3-5.

<sup>5</sup> Borrie and Spencer, *Australia's Population Structure ...* (1965), pp. 21, 23, 43.

<sup>6</sup> Although a greater underenumeration of females than of males during censuses contributes to these patterns, this particular factor does not appear to be of major importance. See El-Badry, "Higher female than male mortality ..." (1969). See also Visaria, "The sex ratio of the population of India ..." (1967).

<sup>1</sup> Sometimes sex ratios are presented as "femininity ratios", i.e., the number of females per 100 males. See, for example, Desai, *Size and Sex Composition of the Population of India ...* (1969).

TABLE VIII.1. ESTIMATED SEX RATIOS OF POPULATION FOR MAJOR AREAS AND REGIONS OF THE WORLD, 1965

(Males per 100 females)

Major areas and regions	Under 15 years	15-64 years	65 years and over	Total
World total .....	103.5	98.9	74.8	99.2
Developing regions .....	103.2	102.3	87.8	102.2
More developed regions .....	104.3	92.8	65.6	93.0
Africa .....	100.3	99.6	82.6	99.4
Western Africa .....	99.5	102.9	84.8	100.9
Eastern Africa .....	99.3	96.9	79.1	97.4
Middle Africa .....	97.8	93.6	77.7	94.8
Northern Africa .....	103.6	100.8	88.1	101.6
Southern Africa .....	99.4	102.4	78.8	100.2
Asia (excluding the USSR)				
East Asia .....	102.8	100.2	80.9	100.3
Mainland region .....	102.7	100.9	82.1	100.8
Japan .....	103.7	95.6	78.6	96.4
Other East Asia .....	103.3	101.1	70.8	100.9
South Asia .....	104.6	104.8	95.7	104.4
Middle South Asia .....	105.5	107.2	103.2	106.3
South-East Asia .....	102.0	98.7	81.3	99.6
South-West Asia .....	104.6	105.4	80.5	104.1
Europe (excluding the USSR)				
Western Europe .....	104.8	95.3	66.6	94.1
Southern Europe .....	104.5	96.0	63.7	93.4
Eastern Europe .....	105.0	93.8	71.8	94.4
Northern Europe .....	104.7	93.2	66.6	93.2
Northern Europe .....	105.1	99.4	65.9	96.0
Latin America .....	103.0	99.4	89.2	100.5
Tropical South America .....	102.3	99.9	86.9	100.5
Middle America (mainland) .....	104.4	97.8	93.4	100.7
Temperate South America .....	103.1	99.9	87.7	100.2
Caribbean .....	102.7	99.0	93.7	100.3
Northern America .....	103.8	97.6	78.4	97.5
Oceania .....	105.3	105.5	74.6	102.8
Australia and New Zealand .....	104.9	104.3	72.5	101.4
Melanesia .....	107.1	112.3	105.7	109.9
Polynesia and Micronesia .....	105.4	108.2	107.7	106.9
USSR .....	104.2	81.3	45.1	84.3

SOURCE: Compiled from data in United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

7. Numerous censuses and surveys in Africa south of the Sahara have recorded unusually low masculinity ratios, for which the reasons are not yet clearly determined. It is known that certain African countries have sustained considerable emigration, particularly of men, but male surpluses recorded in the countries of immigration are insufficient to account for the full extent of the male deficits in other countries. The low masculinity ratios of less than 100 reported at ages under 15 for each of the four regions south of the Sahara are unique among the regions of the world. While the slightly lower sex ratio at birth, which has been consistently observed among populations of African origin, may provide a partial explanation, other factors, as yet not ascertained, must also be involved. Both Western and Southern Africa show higher masculinity ratios at ages 15-64 than among children, a pattern possibly explained by the fact that important foci of migrant labour are located in these

regions. However, much of the migrant labour is drawn from neighbouring countries, and to the extent that this is so, regional sex ratios ought not to be affected. It is possible that owing to the high mobility of men, their enumeration during censuses has often been less complete than that of women. But the insufficiency of data by which these suppositions can be checked leaves doubt as to the principal causes.<sup>7</sup>

8. The table also shows that the variation in sex ratios among the world's regions becomes progressively greater with age. Excluding the small populations of two sub-regions of Oceania which have a very large excess of males, the ratio ranged from 98 in Middle Africa to almost 106 in Middle South Asia for ages under 15 years; from 81 (Soviet Union) to 107 (Middle South Asia) for ages 15-64 years and from 45 in the Soviet Union to more

<sup>7</sup> See United Nations, *Population Bulletin* ... (1965), pp. 15, 18.

than twice as much (103) in Middle South Asia for the group 65 years and over.

9. The final column of the table shows that the sex ratio in the total population averages 93 in the more developed regions and 102 in the less developed regions. Differences in age structure are an important factor in this wide gap, since the developed regions have a much higher proportion of their population in the older ages, where sex ratios are low. The unusually low sex ratio of 84 in the Soviet Union reflects the high human costs of wars which have ravaged that country. The effects of war are also reflected in the low masculinity ratios of a number of European countries. On the other hand, the very high sex ratio of 106 in Middle South Asia appears to be greatly influenced by the prevailing sex differences in mortality, as mentioned earlier.

## 2. AGE STRUCTURE

10. Data on a population's age structure, in combination with a distinction by sex, furnish the basis for many types of demographic analyses. Although the concept of chronological age is precise and unambiguous, census reports on age are subject to errors arising from a variety of causes; these include deliberate mis-statement, a tendency to report ages ending in certain preferred digits and to avoid others, exaggeration of age at the older ages, carelessness in reporting, and ignorance of correct age.<sup>8</sup> Misreporting of age occurs in all populations, though it is more frequent where literacy levels are not high and a large proportion of the population may not know their exact ages. Before age data can be subjected to worthwhile analysis, various smoothing and adjustment techniques may have to be applied in order to eliminate at least some of the effects of faulty age reporting.<sup>9</sup>

11. It is customary to compare the age structure of different populations by means of percentage distributions of the numbers in broad age groups, though other measures are sometimes used to summarize a population's age distribution.<sup>10</sup> Several different indices have also been devised to measure the aging of populations.<sup>11</sup>

<sup>8</sup> See, for example, United Nations, *Methods of Appraisal of Quality* ... (1955), chap. 3; ———, *Demographic Yearbook, 1969* ... (1970), pp. 8-9. Various tests which may be used in assessing the accuracy of age data are discussed in these sources.

<sup>9</sup> For a description of such techniques, see United Nations, *Methods for Population Projections* ... (1956).

<sup>10</sup> See, for example, the discussion in Hauser and Vargas, "Population structure and trends" (1960), p. 29. The median and mean age, though frequently used, are crude and do not take into account the detailed age structure of the population. It has been shown that two populations can vary greatly with respect to their age distributions, yet have the same mean age. Daric, *Viellissement de la population* ... (1948), p. 15; Landry, *Traité de démographie* (1949), p. 142.

<sup>11</sup> Most frequently used is the ratio of persons defined as "old" to total population, although sometimes the number of old persons is related to the working-age population. See Sauvy, "Demographic ageing" (1963), pp. 355-356; his *Les limites de la vie humaine* (1961), chap. 9; and his *Théorie générale de la population*, vol. 1 ... (1966), pp. 49-50. Since changes in the proportion of young at the base of the age pyramid and the old at its summit can take place simultaneously, some analysts have preferred to use an index which shows the ratio between the old and young age groups. See, for example, Valaoras, "Patterns of aging of human populations"

A population's age structure is depicted graphically by a population "pyramid", or histogram, showing the relative frequencies of each sex at the different ages.<sup>12</sup>

12. At the beginning of the twentieth century, Sundbärg observed certain empirical relationships between age structure and the rate of population growth. He identified three types of populations: (a) progressive, having a high proportion of children and a high rate of growth; (b) stationary, having moderate proportions of children and aged persons with slow growth or stationary numbers; and (c) regressive, having a high proportion of aged persons and declining numbers. The following modal proportions in three broad age groups were suggested by the author's analyses.<sup>13</sup>

	Percentage of population		
	Under 15 years	15-49 years	50 years and over
Progressive .....	40	50	10
Stationary .....	26.5	50.5	23
Regressive .....	20	50	30

### (a) Regional variations

13. According to 1965 estimates, the world's less developed regions had about 42 per cent of their populations under 15 years of age, 47 per cent between 15 and 49 years, and 11 per cent 50 years and over. On the other hand, the more developed regions showed proportions in the same three age groups of 28 per cent, 48 per cent and 24 per cent, respectively.<sup>14</sup> These age structures are thus roughly similar to Sundbärg's "progressive" and "stationary" models described above. The "regressive" type of age structure, which implies declining numbers, does not appear in any of the world's regions.

14. In recent studies, it has been common to compare the age structures of different populations in terms of three broad age groups which identify the population of working age (usually defined as 15-59 or 15-64 years), children under working age and persons beyond retirement age. Such an age distribution is shown in table VIII.2 for the various regions. It is seen that, on an average, the more developed regions have 63 per cent of their population in the age group 15-64 years, as compared with only 55 per cent in the developing regions. The latter regions are characterized by a much higher proportion of children and a much lower proportion of old people, reflecting their higher fertility and higher population growth rates.

(1950), pp. 69, 78; Rosset, *Proces starzenia się ludności* ... (1959), pp. 22 ff. The aging of population has sometimes been studied with reference to the female population alone, since the latter is less affected by wars and migration. See Sauvy, *Théorie générale de la population*, vol. 2 ... (1966), p. 52.

<sup>13</sup> See, for example, the discussion of population pyramids in Landry, *Traité de démographie* (1949), pp. 120-124. See also Hollingsworth, *Historical Demography* (1969), pp. 15-19.

<sup>14</sup> Sundbärg, "Sur la répartition de la population ..." (1900), p. 92; and his *Bevölkerungssstatistik Schwedens, 1750-1900* (1907), pp. 4-5. For a comprehensive analysis of different types of age structure, see also Rosset, *Proces starzenia się ludności* ... (1959), pp. 59-77.

15. While not all persons in the so-called working ages actually participate in economic activities, and not all persons outside these ages are dependants, the ratio of persons in dependent age groups to those of working age provides a useful approximation of a population's dependency burden. As shown in table VIII.2, the average dependency ratio in the developing regions is about 81, compared with 59 in the more developed regions. The higher dependency burden of the developing regions places them at an economic disadvantage in relation to the world's more developed regions.<sup>15</sup> The contrast between

<sup>15</sup> However, by taking into account the inequality of consumption requirements at different ages, Kleiman showed that international differences in the dependency burden were considerably less than the unweighted indices of age structure suggest. Kleiman, "A standardized dependency ratio" (1967).

the developing and developed regions is brought out sharply when youth and old-age dependency are examined separately. The youth dependency ratio was about twice as high in Africa, South Asia and Latin America, where there were approximately four young dependants for every five persons of working age, as in Europe, where the corresponding ratio was only two to five. On the other hand, the populations of Northern and Western Europe are seen to have old-age dependency ratios over three times as high as that for developing regions.

16. Age data for the various subregions given in table VIII.2 show that there is no overlap whatsoever between the more developed and less developed regions in the range of percentages in the three broad age groups. Among the more developed regions, the proportion of

population under 15 years of age ranges from 24 per cent in Northern and Western Europe to 33 per cent in Temperate South America, whereas among the developing regions it ranges from 38 per cent in Mainland East Asia to 46 per cent in Middle America, Polynesia and Micronesia. The percentage range for the 15-64 age group is from about 60 to 68 in the more developed regions and 50 to 58 in the less developed regions, while the percentage of old persons ranges from about 6 to 12 in the developed regions and from 2.4 to 4.0 in the less developed regions.

17. The regions having the lowest proportion of children (24 per cent) and the highest percentage of aged persons (12 per cent) in their populations are those of Northern and Western Europe, where fertility decline took place relatively early and birth rates have been at low levels for some time. In Southern and Eastern Europe and the Soviet Union the long-term decline in fertility began later, and it is only recently that birth rate levels in these regions have fallen to levels approaching those in Northern and Western Europe (see chapter IV, section A). The aging process is thus not so far advanced in the former regions, which, on an average, have 7-9 per cent of their populations in the age group 65 years and over, and 27-31 per cent under 15 years. Also within these ranges are the age structures of Australia and New Zealand, and Northern America, where fertility levels since the Second World War have remained somewhat above those in Northern and Western Europe. Japan occupies a unique position in that as a result of the recent rapid fall of fertility in that country, the population structure combines a low percentage of children (26 per cent) with a low percentage of old people (6 per cent) and an unusually high proportion in the working ages (68 per cent).

18. Among the subregions of Africa, the percentage of children in the population varies from about 40 per cent in Southern Africa to 44 per cent in the Northern, Eastern and Western regions. While the latter regions are estimated to have the highest fertility levels currently existing in the world, the relatively high mortality levels still prevailing have a moderating effect on the proportion of young children in the population, with the result that the percentage under fifteen years is no higher, if as high, as that in Tropical South America and Middle America, where both fertility and mortality are lower. South Asia, with 43 per cent of its population under fifteen years of age, has a considerably younger population than does East Asia. Owing to the estimated moderate fertility level of China, the mainland region of East Asia is shown to have about 38 per cent of its population under fifteen years of age. The estimated percentage in the working ages (58 per cent) is higher than that of any other developing region.

19. Figure I shows population age pyramids or histograms for six selected countries, depicting different types of age structure. The pyramids for Mexico and the Philippines are typical of the populations of many developing countries where fertility is high and fairly constant. These pyramids have broad bases and steeply sloping sides, illustrating the large numbers of children and young people, and the small percentage of old people in the

population. At the other extreme are the age structures of two populations of long-standing low fertility, those of Sweden and the United Kingdom. Their histograms are almost rectangular in shape, with a slight sloping at the oldest age groups. Both show indentations at ages 25 to 35 reflecting depressed birth rates of the 1930s, and enlarged cohorts at ages 15-19 as a result of the higher birth rates following soon after the Second World War. The two other pyramids shown in figure I represent transitional populations where fertility has declined more recently. In Japan, where fertility has been falling for several decades, the large cohorts born when fertility was much higher have moved progressively into older age groups creating a bulge. (See section B below.) The shape of this type of pyramid has been variously described as "bee-hive", "Chinese lantern" or "barrel". In Singapore, fertility decline has been very recent and is reflected only in a narrowing at the base of the pyramid.

### (b) Trends

20. It has been estimated that until some two hundred years ago, most of the world's populations had fairly similar age structures, not very different from those of today's developing countries. Since then, and especially over the past fifty to one hundred years, substantial changes in age structure have occurred in the present developed countries as the proportion of children declined markedly, while that in the middle and older age groups increased.<sup>16</sup> Around 1850, the proportion of the population aged sixty-five years and over in Western European countries was about 5 per cent,<sup>17</sup> whereas by 1965 this proportion had reached nearly 12 per cent (table VIII.2). The age pyramids for Sweden and the United Kingdom (Great Britain), for example, which, as seen below, were almost rectangular in shape in 1965, were, around 1850, truly pyramid-shaped, owing to the relatively large numbers of persons in the younger age groups and the progressive attrition from mortality with advancing age.<sup>18</sup>

21. The evolution of the present age structure of the populations of today's developed countries is exemplified by the data for Sweden for various dates since 1750, which appear in table VIII.3. Throughout the period covered by the table there was a steady reduction of mortality; fertility declined sharply between the 1870s and the 1930s, and there was heavy emigration from about 1860 to 1910.<sup>19</sup> These trends are reflected in the population's changing age structure.

22. Children under fifteen years of age constituted about one third of the Swedish population during the period 1750-1800, and this proportion did not change much until after 1900, though there is evidence of a slight increase between the last half of the eighteenth century and the first half of the nineteenth, possibly due to declin-

ing infant and childhood mortality rates. The first major alteration in age structure was a remarkable increase, between 1860 and 1900, in the proportion of persons aged 65 and over, which rose from 5.2 to 8.4 per cent of the total population. This increase was due in part to the heavy emigration between 1860 and 1900, which depleted the ranks of young adults and left the country peopled to an increasing extent by the older generations. After 1900, the increase in the percentage of aged continued, while the proportion of children in the population entered a decline, reflecting the fall of the birth rate. By 1965 children under 15 years of age had declined to 21 per cent of the total population. While the trend in this age group has been consistently downward, the percentage under five years of age in 1950 shows an increase over the 1930 level, as a result of the post-war upswing in the birth rate. By 1965 this cohort had passed into the working-age group.

23. The proportion of adults 15-64 years of age in the Swedish population dropped slightly between 1860 and 1900 owing to the emigration mentioned above. After 1900 it rose sharply as emigration slackened and fertility declined. Since 1930 the proportion in this age group has remained stable at about two-thirds. There has been a considerable aging within the group, however, as the proportion under age 40 has fallen and that age 40 and above has risen. At the same time a steady rise has occurred in the proportion aged 65 and over—from 9 per cent in 1930 to 13 per cent in 1965.

24. The history of changes in the Swedish age structure is repeated in broad outlines, though with many differences in details, in the records for other European countries. In the United Kingdom (Great Britain) the aging

of the population became evident in the early part of the twentieth century. Between 1901 and 1951, the percentage of population aged 65 years and over rose from about 5 per cent to 11 per cent; at the same time the proportion of children under 15 years of age declined from 33 to 22 per cent.<sup>20</sup> In France, the aging of the population began much earlier—in the first half of the nineteenth century, if not before—but it advanced more slowly than in Sweden or the United Kingdom (Great Britain) (see table VIII.4). Already by 1851 over 6 per cent of the population was in the age group 65 years old and above, and children under 15 years made up only 27 per cent of the total. The latter figure remained substantially unchanged, falling only slightly until after 1911; by 1950 it had dropped to 22 per cent.<sup>21</sup> The earlier beginning of aging in France is related to the decline of the birth rate in that country long before the last quarter of the nineteenth century, when the secular decline of fertility became evident in Sweden, the United Kingdom (Great Britain) and many other countries of Northern and Western Europe. (See chapter IV, section A.) Since 1900, the

median age of the population has risen from 24 to 36 years in England, and from 23 to 30 in the United States.<sup>22</sup> Only 4 per cent of the United States population was aged 65 years and over in 1900, but this percentage doubled during the next half century. In both Canada and the United States, the proportion of young children in the population, which had declined from 1900 to 1940, showed a rise in the ensuing decade,<sup>23</sup> owing to the post-war recovery of the birth rate.

25. When these changes in age distribution are translated into dependency ratios, it is found that the fall in fertility in industrialized countries was followed immediately by a decline in the total dependency burden which was sustained for many decades, even after the proportion of old-age dependants began to rise. Eventually, however, the increase in old age dependency outpaced the decline in youth dependency, causing an increase in the total dependency burden.<sup>24</sup> Moreover, as noted above, the upturn in the birth rate in many industrialized countries following the Second World War caused a temporary rise in the youth dependency ratio. The data presented in table VIII.5 show that in France, where the aging process began very early, declines in the total dependency ratio from the mid-nineteenth to mid-twentieth century were modest in comparison with those in the United States.<sup>25</sup>

26. In most countries of Southern and Eastern Europe, where the decline of the birth rate is a relatively recent development, the aging of population has been marked

<sup>22</sup> Coale, "How a population ages or grows younger" (1964), p. 48. The median age in the United States was around 17 years in 1820. Shryock, "The changing age profile of the population" (1950), p. 2.

<sup>23</sup> United Nations, *The Aging of Populations* ... (1956), pp. 96, 99.

<sup>24</sup> Investigating population trends in Europe, Notestein and his associates distinguished three stages of dependency among populations affected by aging: (1) "heavy youth dependency" at the beginning of the aging process, when the proportion of children is high and the proportion of aged persons low; (2) "light dependency", when the ratio of young people to producers has fallen considerably, but without yet being balanced by an increase in the share of aged dependants; and (3) "heavy old-age dependency" in the advanced stages of aging, when the ratio of the aged to the producers is mounting at a rate no longer balanced by the decline in the ratio of children. Notestein *et al.*, *The Future Population of Europe and the Soviet Union* ... (1944), p. 155.

<sup>25</sup> For trends in Belgium, see André, *Le vieillissement de la Belgique* (1969), p. 8.

only in recent decades. Thus, in Portugal, only about 6 per cent of the population was aged 65 years and over at each census from 1890 to 1930, but this proportion rose more rapidly after 1930 and reached 8.6 per cent in 1967. In Italy, a slow aging of the population seems to have been under way from the latter part of the nineteenth century onward. Between 1861 and 1961, the percentage of persons aged 65 years and over increased steadily from 4.0 per cent to 9.5 per cent. The proportion under 15 years of age, on the other hand, fluctuated around 34 per cent between 1861 and 1911, before beginning a steady downward trend, reaching about 25 per cent in 1961. In Bulgaria, where high birth rates were maintained well into the twentieth century, little aging of the population was observed until after 1934. The proportion of old people in the population rose from 5.2 to 8.6 per cent between 1934 and 1965, while during the same period the proportion of children declined from 36 to 24 per cent.<sup>26</sup> In Spain, an aging of the population is observed throughout the twentieth century, except that in 1920 the proportion of persons aged 65 years and over was less than that at the preceding census (1910), possibly owing to the high mortality during the influenza epidemic in 1918,<sup>27</sup> which affected older persons disproportionately.

SOURCES: Compiled from Sauvy, *Théorie générale de la population*, vol. 2 ... (1966), p. 53; Bogue, *The Population of the United States* ... (1959), p. 102.

<sup>26</sup> United Nations, *The Aging of Populations* ... (1956), pp. 126, 144, 153; ———, *Demographic Yearbook, 1968* ... (1969), table 5. Regarding Italy, see also Somogyi, "Evoluzione della popolazione attraverso il tempo" (1965), pp. 28-31; Vinot, "La situazione demografica dell'Italia ..." (1965). Concerning Poland, see Holzer, *Demografia* (1970), pp. 126-127. For trends in aging in different regions of the Soviet Union, see Sachuk, "Ob osobennostiakh starenia ..." (1966), pp. 284-298.

<sup>27</sup> Díez Nicolás, "Estructura por sexo y edades ..." (1969), pp. 15, 18.

27. From the beginning of Japan's modernization, around 1872, to the Second World War, the population showed a clear trend towards rejuvenation. The sharp decline in fertility which followed the war, however, brought about a sudden aging of the population,<sup>28</sup> with the 65 years and over group increasing from 4.9 per cent in 1950<sup>29</sup> to 6.3 in 1965 (table VIII.2). Few Western countries have good statistics which date back to the early stages of their demographic transition, but in Sweden, where such statistics exist, a rejuvenation effect has been observed between the mid-eighteenth and mid-nineteenth centuries, when only mortality was falling. (See table VIII.3 above.)

28. The period since the end of the Second World War has seen opposing trends in the age distribution of the population of different developed regions. In Australia, New Zealand and Northern America, the proportion of young children in the population was greater in the mid-1960s than it had been just after the war owing to the higher post-war birth rates which were maintained in these areas for a time. On the other hand, birth rates generally continued their long-term downward trends in Southern and Eastern Europe with the result that, in most countries of these regions, the proportions of young children in the population were further lowered.

29. The available statistics for most developing countries show little change in age structure from one census to another, except where immigration has occurred on a large scale. The pattern of high percentages of children and low percentages both of adults of working age and aged dependants appears to have persisted throughout the period for which any information is available. Where there is evidence that the age distributions of populations of developing countries have undergone some change, they have, if anything, become somewhat younger. In Taiwan, for example, the median age decreased from 21 to 18 years between 1915 and around 1960.<sup>30</sup> The factors responsible for changes in age structure in some developing countries are discussed in section B below.

## B. Determinants of sex and age structure

### 1. FACTORS DETERMINING SEX STRUCTURE

#### (a) Sex ratio at birth

30. In most diploid forms of life, sex is genetically determined, either at the gene level without visible differentiation of sex chromosomes, or with the evolution of two kinds of sex chromosomes. The latter mechanism operates among human beings. All mature eggs produced by a woman are alike in having one X-chromosome, whereas a man produces two kinds of sperm—those with an X-chromosome and those with a Y-chromosome. Any egg fertilized by an "X sperm" develops into a female

(XX), while fertilization by a "Y sperm" leads to a male (XY). Sex is, therefore, determined at the moment of fertilization.<sup>31</sup>

31. While the discovery early in this century of the chromosome differences between males and females is essential for an understanding of sex determination in human beings, some important questions still remain to be answered. Two of these relate to the sex ratio at conception (primary sex ratio) and the sex ratio at birth (secondary sex ratio). Male and female babies are not born in exactly a one-to-one ratio, the masculinity ratio at birth being most commonly around 105, as previously mentioned. Although this ratio varies relatively little from one population to another, a study by Visaria has found it to be consistently lower among populations of African or negroid origin.<sup>32</sup> The extent to which the excess masculinity of the sex ratio at birth and observed variations in this ratio are due to genetic, biological or socio-environmental factors is not known.

32. It has been observed that in the past the sex ratio was higher among legitimate than among illegitimate babies, and that this difference has lessened in recent times. Also, the often reported higher sex ratio at birth for rural, as compared to urban, populations now appears to have virtually disappeared.<sup>33</sup>

33. Moore has shown that the trend in the sex ratio at birth in England and Wales over a period of some fifty years (1901-1954) was slowly, but rather consistently rising, from about 103 to about 106. This change, according to Moore, could have been due to changes in the average age of the mothers. Examining data for 1947-1952, he found a definite drop in the sex ratio at birth with the increasing age of the mother (the sex ratio was almost 108 for mothers aged 15-19, dropped to 106 for mothers aged 20-24, and remained about 105 for mothers of more advanced ages).<sup>34</sup>

34. The sex ratio has been shown to vary also with the order of birth. In many populations, the sex ratio is highest at the first births and tends to decrease with successive births. Analysing data for whites in the United States of America for 1947-1952, Novitski and Sandler found that the sex ratio dropped from 106.6 for first births to somewhat less than 105 for births of the orders of seven and above.<sup>35</sup> Lejeune and Turpin found that the sex ratio diminished linearly with the increasing age of the father and to a lesser degree, with the increasing age

<sup>31</sup> See Stern, *Principles of Human Genetics* (1960), p. 400; Srb, Owen and Edgar, *General Genetics* (1965), chap. 2. Also, Fisher, *The Genetical Theory of Natural Selection* (1958), p. 158; Hamilton, "Extraordinary sex ratios" (1967).

<sup>32</sup> Visaria, "Sex ratio at birth in territories ..." (1967), pp. 136-139.

<sup>33</sup> For a discussion of these and other fluctuations in the sex ratio at birth, see Stern, *Principles of Human Genetics* (1960), p. 430. Earlier studies by William Farr, R. Mayo-Smith and others are discussed in Knibbs, *The Mathematical Theory of Population* ... (1917), pp. 136-137. See also Colombo, "On the sex ratio in man" (1957).

<sup>30</sup> Coale, "How a population ages or grows younger" (1964), p. 48.

of the mother.<sup>36</sup> Such correlations can be the result of various components. They may be directly related to birth order itself, to the age of the parents, or to a more complex system of causes.<sup>37</sup>

35. The sex ratio of stillbirths is much higher than the sex ratio at birth,<sup>38</sup> and therefore an inverse relation of the sex ratio at birth and the frequency of pregnancy wastage might be expected. However, Visaria did not find a statistically significant correlation between these two variables.<sup>39</sup> Another implication of the high masculinity of foetal deaths is the possibility that the sex ratio at conception may be still higher than the sex ratio at birth. The inference is a subject of dispute, however, because the size and direction of sex-selective foetal mortality in the early weeks after conception, if such a mortality differential does exist, is highly uncertain, as much early pregnancy loss escapes observation and, in any event, sex is not identified.<sup>40</sup>

36. A difference in sex ratios at birth between negroid and other populations was shown in a study by Visaria, which found that in forty-nine of sixty-three populations, not including a large proportion of population classified as negroid, black or African, the sex ratio lay between 104.0 and 107.0. On the other hand, in fifteen of seventeen countries or territories where the population of negroid origin made up more than one third of the total, the sex ratio at birth fell below 104.0. This evidence, together with the persistent difference between the sex ratio at birth in the white and non-white populations of the United States (which continues despite improvements in the completeness of birth registration and reductions in pre-natal mortality), led the author to conclude that the slightly lower ratio for negroid populations may have a genetic basis.<sup>41</sup> It is possible that in other parts of the world for which accurate observations are still lacking, sex ratios at birth may also differ significantly from those most commonly recorded.

37. An increase in the sex ratio at birth during and immediately following the First World War was noted by Savorgnan, both in warring and neutral countries. Mackenroth made similar observations regarding the Second World War.<sup>42</sup> In the Soviet Union, where the sex ratio at birth used to fluctuate around 105-106, it rose to

107.4 in 1944 and to 109.1 in 1945.<sup>43</sup> In the United States, however, McMahan showed that the sex ratio was not appreciably altered during and after the years of the two world wars.<sup>44</sup> Although it is now generally admitted that there is no evidence that the masculinity of births is directly affected by war, war can cause shifts in the ages of parents or in the orders of births which occur most frequently. It is also possible that war-time conditions produce more early foetal loss. All of these factors may affect the sex ratio at birth.

#### (b) Sex differences in mortality

38. As shown in chapter V, in most countries with good statistics mortality rates are higher for males than for females, although some deviations from this pattern have been observed in certain age groups.<sup>45</sup> Under usual mortality conditions, as pointed out above, the sex ratio of somewhat more than 100 at birth tends to be gradually reduced with advancing age, eventually falling below 100.

39. Abnormal mortality conditions, especially war casualties, can cause wider discrepancies in the numbers of men and women surviving. Severe deficits in men, relative to the numbers of women, are noted in the Soviet Union, where according to the 1959 census there were 21 million fewer males than females.<sup>46</sup> The effects of war are also reflected in the low masculinity ratios for a number of European countries. Notestein and his colleagues showed that the expected sex ratio for Germany in 1925, had the First World War not occurred, was 98.8, whereas the actual ratio was 93.9. They further estimated that the population of England and Wales in 1926 was about one million smaller than it would have been without the war, and that four-fifths of this deficit was concentrated among males.<sup>47</sup>

40. The effects of the two world wars on the balance of the sexes in a few selected countries can be seen in table VIII.6. For three of the four countries, the data for around 1920 show particularly low sex ratios in the 20-44 age group, which includes the survivors from the cohorts who were of military age during the First World War. Japan, which was not involved in the hostilities, is an exception. By 1950 these cohorts had moved into the older ages, and low ratios are observed in the age group 45-64 years. The effects of the Second World War on

sex ratios are visible in the data for around 1950. The heavy war casualties suffered by Poland and Japan are reflected in their low sex ratios for the 20-44-year age group. In France and the United Kingdom (England and Wales), the sex ratio was affected to a lesser degree by the Second World War than by the First, due to lighter military losses. Moreover, France's war-caused male deficit had been filled in by post-war immigration so that by 1950 males outnumbered females in the 20-44-year age group.<sup>48</sup>

#### (c) Sex-selective migration

41. While international migration is ordinarily sex-selective, in most countries the volume of immigration or emigration is not sufficient in relation to the total population to have much noticeable effect on its sex composition. Since migrants are generally concentrated in the young working ages, however, the effect on the sex structure at these ages is usually more noticeable than in the population as a whole. As noted in chapter VII, section C, variations and exceptions to the predominant sex and age structure of migrants are not uncommon, and among intercontinental European migrants the proportion of family units has been increasing.

42. Argentina was one of the countries in the Western Hemisphere most affected by immigration late in the nineteenth century and early in the twentieth century. In 1914, when 30 per cent of its population was foreign-born and the latter had a sex ratio of 171, the sex ratio of the total population reached 116.<sup>49</sup> In 1950 in Brazil, the sex ratio of the native-born population was 98.7, while that of the foreign-born population was 127.3, giving the total population of the country a sex ratio of 99.3.<sup>50</sup>

<sup>50</sup> Mortara, "The development and structure of Brazil's population" (1954), p. 124.

43. In the United States until 1910, immigrants from abroad were predominantly males, especially in the flood-tide of immigration around the turn of the century when the proportion of the foreign-born attained almost 15 per cent of the total population. As a result, the sex ratios among the foreign-born increased from 123.8 in 1850 to 129.2 in 1910. In more recent years the flow of immigrants was notably reduced; furthermore, the number of female immigrants came to equal, even to surpass slightly, that of males. The Negro sex ratio, on the other hand, has been consistently below that of the native-born white population. Nevertheless, the weight of immigrants has been such that the combined total population had consistently higher sex ratios than the native white. Only by 1950, as a result of reduced immigration, and a greater sex balance among the immigrants, did the sex ratios of the total and of the native white population come into a coincidence.<sup>51</sup>

44. Singapore provides a more detailed example of the influence of sex-selective immigration on the sex structure. Sex ratios for each of the main ethnic groups—Chinese, Malaysians, Indians, Pakistanis, Europeans—have undergone considerable fluctuations which reflect to a large extent the varied rates of inflow of migrants. During the nineteenth century all of the above-mentioned groups had exceedingly high sex ratios, but the Malaysians, with a large indigenous component, had considerably lower ratios than the others. In each of these groups, a downward trend extending to the most recent census is noted (see table VIII.7). The non-immigrant character of the Eurasian population is reflected in its low sex ratio throughout the period.<sup>52</sup>

45. Internal migration is also usually selective with respect to sex and, wherever its volume is considerable, it can produce substantial differences in the sex composition of different sectors or regions of a country. This was true of the United States of America in the nineteenth century, for example. In 1850, sex ratios in the north-eastern and southern states were relatively low (slightly

\* Including Ceylonese.

above 100), while those in the western regions were extremely high (about 280).<sup>53</sup> The prevalence of males in newly settled territories appears to account for most of these differences.

46. Statistical data indicate that in many parts of the world the sex ratio is lower in urban areas than in rural areas—that is, women outnumber men in the urban areas—with the result that the sex ratio remains high in the rural areas. In Europe and regions of overseas European settlement, including most parts of Latin America, this pattern of low urban sex ratios is prevalent; however, among African and Asian populations, where males predominate in rural-to-urban migrations, the opposite is usually observed.<sup>54</sup> In the United States of America, the urban population has had more women than men since 1920, while in both rural non-farm and rural farm areas men have exceeded women in number. In 1950, the sex ratio for rural farm areas was 110 and that for rural non-farm areas was 104, while the urban sex ratio was only 95.<sup>55</sup> In Sweden, urban and rural sex ratios in 1960 were 95 and 113, respectively. This pattern of higher masculinity ratios in rural areas has been observed in some developing countries as well. In Mexico and Costa Rica, for example, the urban sex ratios in 1950 were 90 and 87, respectively, while the corresponding rural ratios for the two countries were 103 and 107. In contrast, the sex ratios in India in 1951 were 116 in urban areas and 104 in rural areas, while the corresponding ratios for Turkey in 1950 were 108 and 99.<sup>56</sup>

<sup>56</sup> United Nations, Economic Commission for Latin America, "The demographic situation in Latin America" (1961), pp. 37-38. Swedish data for 1960 computed from United Nations, *Demographic Yearbook, 1963* ... (1964), table 5. In India, the pattern of high masculinity in urban areas has remained consistent in all census years since 1891. The sex ratio increased during 1891-1941, from 112.2 to 122.8 in urban and from 103.7 to 104.8 in rural areas. See Davis, *The Population of India and Pakistan* (1951), p. 139.

#### (d) Age composition

47. The sex ratio of the total population is affected by the population's age structure, as mentioned in section A. Because masculinity ratios are usually relatively high among the young age groups, populations which have a large proportion of young people have higher over-all masculinity ratios than older populations. In the latter, the cumulative effects of unfavourable male mortality in the relatively large older-age contingents contribute to a lowering of the over-all masculinity ratio.

### 2. FACTORS DETERMINING AGE STRUCTURE

48. As stated in section A, the age structure of a population is mathematically determined by the levels of fertility, mortality and migration, or, in cases where the latter factor is negligible, by the first two alone. Until fairly recently, the effects of changes in these variables on age structure were not very well understood, but the pioneering work on the development of demographic models, which began in the early 1950s, has led to a greatly improved knowledge of these relationships. Two methods may be applied for studying the effects of different levels of fertility and mortality upon a population's age structure. If given levels of fertility and mortality prevail for an indefinite period of time, admittedly a hypothetical situation, a population of constant age structure results, known as a "stable population".<sup>57</sup> Given the assumed levels of fertility and mortality, one can estimate the corresponding age structure that would result from their indefinite continuance. The comparison of stable population models differing in assumed fertility levels, mortality levels, or both, permits an inference of the long-run effects of such levels upon the age structure.

49. If, on the other hand, the effects on a population's age structure of variations over time in the fertility level, mortality level, or both, are to be deduced, models may be calculated, using the "component method" technique of population projection (see chapter XV).

<sup>57</sup> See the discussion of stable population in chapter III, section G. The theory of stable population and the interrelations of demographic variables and their role in determining age structure was developed by Lotka. See particularly his *Théorie analytique des associations biologiques* (1939), vol. 2.

TABLE VIII.8. AGE DISTRIBUTION OF MODEL STABLE POPULATIONS CORRESPONDING TO DIFFERENT LEVELS OF FERTILITY AND MORTALITY

Gross reproduction rate	Percentage of population			Gross reproduction rate	Percentage of population		
	0-14 years	15-59 years	60 years and over		0-14 years	15-59 years	60 years and over
<i>Expectation of life at birth: 20 years</i>				<i>Expectation of life at birth: 50 years</i>			
1.0	14.8	68.3	16.9	1.0	17.8	60.7	21.5
2.0	28.9	64.0	7.1	2.0	34.2	57.2	8.6
3.0	38.5	57.6	3.9	3.0	44.6	50.9	4.5
4.0	45.2	52.4	2.4	4.0	51.5	45.8	2.7
<i>Expectation of life at birth: 30 years</i>				<i>Expectation of life at birth: 60.4 years</i>			
1.0	16.3	65.0	18.7	1.0	18.7	59.4	21.9
2.0	31.4	60.9	7.7	2.0	35.6	55.8	8.6
3.0	41.3	54.5	4.1	3.0	46.0	49.6	4.4
4.0	48.2	49.2	2.6	4.0	52.9	44.4	2.7
<i>Expectation of life at birth: 40 years</i>				<i>Expectation of life at birth: 70.2 years</i>			
1.0	17.0	62.6	20.4	1.0	19.5	58.6	21.9
2.0	32.9	58.8	8.3	2.0	36.8	54.7	8.5
3.0	43.1	52.5	4.4	3.0	47.3	48.4	4.3
4.0	50.0	47.3	2.7	4.0	54.1	43.3	2.6

SOURCE: United Nations, *The Aging of Populations* ... (1956), p. 27.

Since different assumptions can be introduced regarding the timing and extent of changes in the fertility and mortality levels, this procedure is somewhat more complicated than a systematic comparison of stable populations, where only two factors can vary (namely, a constant fertility level and a constant mortality level). The projection method is highly useful, however, in illustrating the demographic consequences of particular fertility or mortality assumptions over a short period of time.

50. In either of the two methods described above, a third demographic variable—migration—may be introduced. Thus, stable age distributions can be calculated assuming a constant rate of immigration or emigration continuing indefinitely, in addition to fixed fertility and mortality rates.<sup>58</sup> Also, in calculating population projections, assumptions concerning future migration can be included, along with the fertility and mortality assumptions, thus adding to the possible number of variants.

51. Most projections designed to illustrate the influence of demographic trends upon age composition have been calculated with reference to populations which have actually been observed, past changes therein, or future changes which can be envisaged as likely. In those which concern a past period, the object is often to determine the population that would have resulted had one or another demographic factor followed a different trend. Other projections are made into the future with selected assumptions in order to examine the consequences of varying assumptions. Numerous projections of this kind have been calculated by various authors. In each instance the variation of one factor (fertility, mortality, migration) has an effect on the population's rate of growth, on the size it attains at particular points in time, and on its age composition. The findings of some of these analyses with respect to the last-named effect are discussed below.

#### (a) *The effects of mortality*

52. Table VIII.8 shows the structures of twenty-four stable population models constructed according to different levels of mortality and fertility. Mortality levels are expressed in terms of expectation of life at birth by means of corresponding life tables.<sup>59</sup> Fertility levels are expressed in terms of gross reproduction rates, with assumed average age patterns of birth frequencies to women in reproductive ages. For simplicity, only three broad age groups are shown: 0-14 years, 15-59 years, and 60 years and over. Both in respect to mortality and fertility, an extreme range is covered, namely expectation of life at birth from 20 to 70 years, and gross reproduction rates from 1.0 to 4.0. Some of the combinations, admittedly, will hardly ever be approximated by an actual population.

53. If populations of identical fertility, but different mortality, are compared from this system of models, the observed differences in age structure are directly attributable to the difference in mortality levels. With very low fertility ( $GRR = 1.0$ ) and very high mortality ( $e_0 = 20$ ), for instance, 14.8 per cent of the population is aged 0-14 years, 68.3 per cent 15-59 years, and 16.9 per cent 60 years and over. With equally low fertility, but with very low mortality ( $e_0 = 70.2$ ), the three percentages are 19.5, 58.6 and 21.9, respectively. Generally speaking, with fertility levels equal, the populations of lower mortality will have larger percentages in childhood ages, larger percentages in the most advanced ages, and consequently reduced percentages in the middle-age group.

54. The effect of differences in mortality levels on age structure diminishes at the higher expectations of life. For example, when stable populations with  $GRR = 1.0$ ,

<sup>58</sup> See Hyrenius, "Reproduction and replacement rates" (1955).

<sup>59</sup> United Nations, *Age and Sex Patterns of Mortality* ... (1955); *Methods for Population Projections by Sex and Age* (1956). Population models of much greater detail, and separately for each sex, have been elaborated by Coale and Demeny in their *Regional Model Life Tables* ... (1966).

and life expectations of 20, 40, 60.4 and 70.2 years are compared, it is seen that the difference in age structure is greater between life expectancies of 20 and 40 years than between 40 and 60.4 years, and that the age structure of the stable population having an expectation of life of 70.2 years differs little from that where life expectation is 60.4 years. Similar observations can be made for stable populations of higher fertility levels.

55. Aside from the effect of differing mortality levels on age structure under stable population conditions, much interest has attached to the effects of changes in mortality levels over time. The effect of mortality decline on age structure depends on the pattern of change in survival rates for the different age groups. If the probability of surviving a fixed number of years increases in the same proportion at all ages, the age structure of the population remains unchanged.<sup>60</sup> On the other hand, greater percentage improvements at the older ages raise the proportion of older persons in the population, while a larger percentage rise in survival ratios at infancy and early childhood has the same effect as an increase in fertility, namely to raise the proportion of children in the population.

56. Since, in actual populations, the death risks have been greatest at the two extremes of life, there has been a wider scope for mortality improvement in early childhood and at advanced age than in adolescence and early adulthood. Thus, the result of mortality change alone would be to increase the proportions of young and old in the population at the expense of the intermediate age groups. In most of the industrialized countries during the past century the greatest improvements in mortality have occurred at the young ages. From an examination of mortality records for selected countries from the latter half of the nineteenth century to the 1950s, Coale found that, in the absence of fertility change, mortality decline would have lowered the median age of the population in 40 of 44 cases.<sup>61</sup> Keyfitz found similar trends in his analysis of long-term data for Sweden and the United Kingdom (England and Wales). More recent trends in these countries, as well as in Australia, Canada, and the United States, however, indicated that mortality change had increased the mean age of population.<sup>62</sup> In populations like those of the above-mentioned countries, which have already attained a high expectation of life, there is not room for further large increases in survival ratios at infancy and early childhood. Therefore, the most significant future mortality reductions in such populations may

come at the advanced ages, causing a rise in the proportion of older persons in the population.<sup>63</sup>

57. As mentioned above, population projections have often been calculated to examine what the demographic effects would have been in a particular country if mortality had followed a different trend from that observed. The findings have generally shown that the resulting age structure would have been modified to only a modest extent, assuming that changes in other demographic variables occurred as they actually did.

58. For example, Valaoras's projections of the population of the United States from 1900 to 1945 under different assumptions showed that, given actual fertility trends, the ratio of old persons to children in the population would have been somewhat greater had mortality remained constant throughout this period rather than declining as it did. The reason for this finding was that mortality rates declined proportionately much more at the ages of infancy and childhood than at the older ages.<sup>64</sup> Hermalin extended Valaoras's work by projecting the United States population from 1900 to 2000 in two segments (1900-1960, and 1960-2000). He showed that during the first period, mortality decline, although affecting age structure only slightly, appears to have produced a somewhat younger population. Mortality improvement during the second period, on the other hand, is expected to make the population somewhat older.<sup>65</sup>

59. The small effect of changes in mortality on age distribution was shown by Coale in his projections of the female population in Sweden from 1860 to 1950, on several assumptions. The results showed that if mortality had remained at its 1860 level throughout the period, the resulting age distribution in 1950 would have been similar to the actual.<sup>66</sup>

60. Although moderate mortality changes have only slight effects on population age structure, large and rapid mortality declines, such as those experienced in recent years by certain developing countries, can modify age structure noticeably as a result of disproportionately high mortality reductions in the younger age groups. In Latin America, for example, the increase of life expectancy by over 30 per cent between the 1930s and 1960s had the effect of reducing the mean age of the population. Among ten Latin American countries studied by Arriaga, the mortality reductions during this period were estimated to have rejuvenated the populations by 0.7 years on average, the reduction in mean age ranging from 0.5 years

<sup>63</sup> See Stolnitz, "Mortality decline and age distribution" (1956), p. 213; and his "A century of international mortality trends: II" (1956), p. 40.

<sup>64</sup> Valaoras, "Patterns of aging of human populations" (1950).

<sup>65</sup> Hermalin, "The effect of changes in mortality rates ..." (1966). Notestein studied developments between 1930 and 1955 in the female population of the United States, and found that reductions in mortality in the period, while saving many lives, had very little effect on the age distribution. Notestein, "Mortality, fertility, the size-age distribution ..." (1960), pp. 271-272.

<sup>66</sup> He also found that if mortality had been at the 1950 level throughout the 90-year period, the 1950 age distribution would have been nearly identical with the actual. Coale, "How the age distribution of a human population is determined" (1957), pp. 87-88. See also his "The effects of changes in mortality ..." (1956), p. 94.

in Brazil to 1.3 years in Venezuela. During the same period, the percentage of the population under 15 years was estimated to have increased from 41.5 to 44.8 per cent.<sup>67</sup> In seven of eight developing countries studied by Keyfitz, actual mortality declines in recent years would have lowered the mean age of the populations, in the absence of any counterbalancing changes in fertility.<sup>68</sup> It has been pointed out, however, that under conditions of high fertility the effects even of drastic mortality change upon age structure are limited. For example, in a population with a gross reproduction rate of 3 and a life expectancy of 70 years, the proportion of persons over 60 would increase from 4.3 to only 9.1 per cent under conditions of immortality, i.e., if death were wholly avoided.<sup>69</sup>

61. The noteworthy observation has been made that a population in which fertility has remained relatively constant while mortality has declined, has an age structure very similar to that which would result if the same current mortality levels had prevailed throughout an indefinite past period, instead of only recently. This is so because of certain compensating effects of the varying mortality levels to which the different cohorts were subjected throughout their life span. The age structure resulting from constant fertility and diminishing risks of mortality has been labelled "quasi-stable". The resemblance of such populations to stable populations has been utilized in recent years to estimate demographic characteristics (e.g. fertility levels) for a number of developing countries having inadequate statistical data.<sup>70</sup>

62. This practical application is possible since the populations of countries in Africa, Asia and Latin America meet the criteria of quasi-stable populations. Rather recently it has become clear that the age structure of a population which has experienced declining mortality may differ enough from the stable to produce errors of some consequence in the demographic measures obtained by applying the usual techniques of stable population analysis.<sup>71</sup>

#### (b) *The effects of fertility*

63. From the models presented in table VIII.8, it is seen that far more extreme differences in age structure occur between stable populations having similar mortality, but different fertility levels, than in the reverse case examined above. For example, if expectation of life at birth is assumed to be 50 years, the population with a gross reproduction rate of only 1.0 will consist of 17.8 per

cent in the age group 0-14 years, 60.7 per cent in the age group 15-59 years, and 21.5 per cent aged 60 and over. With a gross reproduction rate of 4.0, the three percentages become 51.5, 45.8 and 2.7 respectively. Comparisons made at other mortality levels show similar differences. It is thus clear that compared to the minor variations of age structure associated with different mortality levels, the variations of age structure resulting from different fertility levels are indeed enormous.

64. The models also show that for any given mortality level, the differences in age structure become greater as fertility declines. Passing from a gross reproduction rate of 4.0, to 3.0, 2.0 and 1.0, respectively, the percentage of the population aged 0-14 years is seen to decline by increasing amounts, while the proportion aged 60 and over rises by increasing amounts.

65. The effects of changing fertility on age structure within a given population are more complex than the effects of constant differences in fertility between populations, and have not been studied so systematically, except for isolated attempts.<sup>72</sup> The relation between fertility decrease and population aging became an important subject of demographic analysis in the early 1950s. Before that time, it was generally believed that declines in both mortality and fertility, which were characteristic of Western countries, had worked together to bring about an aging of the population: while declines in fertility eroded the base of the age pyramid, it was thought that declines in mortality which permitted people to live longer raised the proportions in the older age groups. Later works, however, demonstrated unambiguously that the past changes in the age structure of the populations of Western countries and of Japan have resulted primarily from declines in fertility. In his study of aging in the United States, Valaoras found that declining fertility was the decisive factor, and that both immigration and declining mortality had a retarding effect on the process of aging between 1900 and 1945.<sup>73</sup> Bourgeois-Pichat calculated that if fertility had remained constant in France from 1776 to 1951 while mortality declined according to its actual pattern, the population would have remained a youthful one, with only 3.6 per cent aged 65 years and over in 1951, compared to 4.3 per cent in 1776; the actual proportion in the 65 and over age group in 1951 was 11.5.<sup>74</sup>

66. The term "transitional" population has sometimes been used to describe the shape of an age pyramid formed

TABLE VIII.9. CHANGES IN PERCENTAGE AGE COMPOSITION CALCULATED IN A POPULATION PROJECTION FOR JAPAN, 1960-2000

Age (years)	1960	1965	1970	1975	1980	2000
All ages .....	100.0	100.0	100.0	100.0	100.0	100.0
0-4 .....	8.4	7.9	7.5	8.0	8.0	6.4
5-14 .....	21.5	17.2	15.2	14.3	14.4	12.6
15-24 .....	19.2	20.8	19.6	15.7	13.8	14.1
25-44 .....	28.6	30.6	32.5	34.1	33.2	25.1
45-64 .....	16.6	17.2	18.3	20.1	22.0	28.1
65 and over .....	5.7	6.3	6.9	7.8	8.6	13.7

SOURCE: United Nations, *World Population Prospects as Assessed in 1963* (1966), p. 128. The example cited is a modification of a projection first published by Japan, Institute of Population Problems, *Future Population Estimates for Japan by Sex and Age* (1960).

under the influence of declining fertility.<sup>75</sup> In actuality, age pyramids of populations undergoing fertility decline vary depending on the speed and extent of the decline. Moreover, irregularities in an age structure may occur, for example, as a result of war-time conditions, when military casualties and separation of husbands from their wives depress fertility. On the other hand, a recovery of fertility from previously lower levels may occur during post-war periods or following improved economic conditions.

67. The temporary "bulging" of the population which often occurs at intermediate age groups during or after a period of fertility decline is an important phenomenon. When the birth rate declines, cohorts of older children may be larger than those born more recently. As time progresses and the relatively large cohort of children advances in age, a "bulge" results first at young adult ages and later at mature and more advanced ages. A recent population projection prepared for Japan provides an example of such a development (see table VIII.9). An exceptionally rapid decrease in fertility occurred in Japan between 1947 and 1957 and by the latter 1950s the gross reproduction rate had reached the very low level of about 1.0. As a result of these trends, 8.4 per cent of the population were 0-4 years old in 1960. According to the projection, this proportion would fall further to 7.9 per cent in 1965 and 7.5 in 1970, but was expected to rise again to 8.0 per cent in 1975 and 1980, partly owing to the increased proportion of population in the reproductive ages. The cohort born in the late 1940s when fertility was still moderately high can be expected to reach the peak child-bearing ages during the early 1970s. The projections show the proportion in the 25-44, year age group reaching a peak of 34 per cent in 1975. By the end of the century, however, the large cohorts would have passed into the older age groups and the proportions both in the reproductive ages and in early childhood might be considerably smaller than at present. This progression of a large cohort through the age pyramid has repercussions on the crude birth and death rates, as discussed in section C below.

<sup>75</sup> Notestein et al., *The Future Population of Europe and the Soviet Union* ... (1944), p. 109.

68. Because of the relationship between age composition and the previous trend in the birth rate, methods have also been developed to utilize the former in estimating past trends in births. Such techniques may be used either because birth data are lacking or unreliable, or for checking the consistency between recorded births in past periods and the numbers currently in particular age groups.<sup>76</sup>

#### (c) The effects of migration

69. At least in theory, a stable age structure can also result in a population affected by emigration or immigration. As mentioned earlier, this would happen when migration occurs at a rate in fixed proportion to the size of every age group in either the sending or receiving countries at each moment of time.<sup>77</sup> Populations affected by the action of mortality and fertility only are considered to be "closed" populations, while those also influenced by migration are "open". While migration at continuing rates can maintain a stable age structure in an "open" population, a discontinued migratory flow can cause an age structure to be progressively deformed as the former migrants advance in age.<sup>78</sup>

70. Since the volume of migration often fluctuates appreciably over time, it is difficult to generalize about its impact on age structure. Moreover, the ratio of net migration to a country's population is seldom large enough to affect its age structure significantly. Net immigration tends to decelerate the process of aging if it increases the younger age groups by a larger fraction than it adds to the older age groups, particularly if the young immigrants also add proportionately to the flow of births. If, on the other hand, net immigration contributes mainly to the increase of those in their late 30s and beyond, it tends to accelerate the aging process, since the immigrants themselves move into the older age groups without

<sup>76</sup> See, for example, Coale and Zelnik, *New Estimates of Fertility* ... (1963), pp. 82-89; Keyfitz, Nagnur and Sharma, "On the interpretation of age distributions" (1967).

<sup>77</sup> For a theoretical treatment of the migration ratio as a function of age and time, see Knibbs, *The Mathematical Theory of Population* ... (1917), pp. 18-25, 431-439.

<sup>78</sup> See, for example, Spengler, "Aging populations: mechanics, historical emergence, impact" (1963), pp. 31-32.

having increased the flow of births significantly.<sup>79</sup> The opposite observations apply to countries of emigration.

71. As pointed out in chapter VII, section C, international migrants are often highly concentrated in the young adult age groups. According to a grouping made by Sauvy of nearly one million immigrants to Australia, Canada, the Federal Republic of Germany and the United States of America in 1961, about 60 per cent of the total number were between 20 and 40 years of age, while in two European populations with age structures relatively unaffected by wars—those of Bulgaria and Sweden—the percentage of persons in these age groups was only 32.<sup>80</sup> The primary effect of a flow of emigration is likely to be a reduction in the proportion of persons in the 20 to 40 age group. In sum, the effect on age structure of migrations extended over a period of time depends on the size of the migratory flow, whether it is increasing or decreasing, and the age structure of the migrants.

72. There are also secondary effects on the age structure in so far as migration influences the birth rate by changing either the sex ratio or the proportion of population in the reproductive ages. A sizable immigration tends to create a noticeable “bulge”, and emigration a “hollow”, in the age structure of the population, phenomena which in the short run tend to offset or to accentuate any excess or deficiency in the working-age population, and in the long run tend to increase (immigration) or to decrease (emigration) the process of aging. Writing in 1950, Sauvy calculated that, assuming constant fertility, a net immigration of at least 100,000 persons per year would be required in France to prevent a fall in the ratio of productive to dependent age groups.<sup>81</sup>

73. Population projections prepared for a number of countries which have taken migration into account have shown that the effects of immigration or emigration on age structure would not be significant. This was the case, for example, with projections prepared for the United Kingdom<sup>82</sup> and the United States of America.<sup>83</sup> Also, where future migratory movements were taken into account in the population projections prepared by the Organisation for Economic Co-operation and Development (OECD) for its member countries, the effects upon age structure were found to be relatively small.<sup>84</sup>

74. Hypothetical studies have also been made on this subject. A United Nations study which examined the effects on age structure of a hypothetical flow of migrants

continuing over a thirty-year period and amounting annually to 1 per cent of the population found that an emigration at this rather high rate would result in an increased old-age dependency burden. With net immigration, on the other hand, old-age dependency was shown to decline. But the ratio of children to young adults was found to rise some time after the onset of immigration, as the young immigrants produced new families. These effects occurred only so long as the migration continued. After immigration ceased, this ratio declined and the ratio of the aged population to young adults, which had increased slowly during the period of immigration, rose rapidly.<sup>85</sup> Few countries in recent years have experienced emigration or immigration of the magnitude assumed in these models.

75. Internal migration also is selective with respect to sex and age and can have much bearing on the structure of population of a given area. Rural-urban migration has contributed substantially to the rather high proportion of young and middle-aged people often found in cities and towns. The exodus from the countryside then tends to generate marked differences between the age structures of urban and rural populations. Rural areas often contain a higher proportion of aged persons than do the urban areas. In Sweden, the percentage of total population aged 65 years and over was 9.0 in rural areas and 6.0 in urban areas in 1900. By 1945 these proportions had increased to 11.0 and 8.4, respectively. Moreover, as table VIII.10 shows, the difference was greater among males than females. The urban-rural differences followed a very regular pattern in France at the time of the 1946 census: the proportion of the population at ages 65 and over was highest in the rural areas (12.8 per cent), and tapered off with increasing size of locality to 10.7 per cent in urban areas with less than 5,000 inhabitants, 9.8 in towns with between 5,000 and 10,000 inhabitants, 9.4 for communities with 10,000 to 50,000 inhabitants, and 8.6 for communities of 50,000 or more inhabitants. Again, as in Sweden, the differences were greater among males than among females.<sup>86</sup>

#### (d) *The effects of war*

76. The effects of war upon a population's age structure are not confined to direct losses attributable to mortality. Fertility is also affected, both during the war when men are separated from their wives, in the immediate post-war periods when there is often a recovery of births deferred during the war, and in subsequent generations when the smaller cohorts born during a war enter the reproductive ages and produce, in turn, relatively smaller cohorts of infants and young children. The effects of war can thus send ripples, or even waves, through the age structure of several future generations.<sup>87</sup>

TABLE VIII.11. AGE DISTRIBUTION AND CRUDE VITAL RATES OF SELECTED MODEL STABLE POPULATIONS CORRESPONDING TO DIFFERENT LEVELS OF FERTILITY AND MORTALITY

		Expectation of life at birth (years)				
		30	40	50	60.4	70.2
Gross reproduction rate: 3.00						
Age (in years)		Percentage distribution				
All ages	100	100	100	100	100	100
0-14 years	41.3	43.1	44.6	46.0	47.3	
15-44 years	45.0	43.4	42.3	41.5	40.7	
45-59 years	9.5	9.1	8.6	8.1	7.7	
60 years and over	4.1	4.4	4.5	4.4	4.3	
Crude vital rates		Per 1,000 population				
Birth rate	47.7	46.0	44.9	43.8	42.9	
Death rate	33.7	23.3	15.8	9.6	4.8	
Rate of natural increase	14.0	22.7	29.1	34.2	38.1	
Gross reproduction rate: 2.00						
Age (in years)		Percentage distribution				
All ages	100	100	100	100	100	
0-14 years	31.4	32.9	34.2	35.6	36.8	
15-44 years	46.8	45.3	44.3	43.6	43.1	
45-59 years	14.1	13.5	12.9	12.2	11.6	
60 years and over	7.7	8.3	8.6	8.6	8.5	
Crude vital rates		Per 1,000 population				
Birth rate	32.7	31.7	31.1	30.6	30.1	
Death rate	33.6	23.7	16.8	11.1	6.8	
Rate of natural increase	-0.9	8.0	14.3	19.5	23.3	
Gross reproduction rate: 1.00						
Age (in years)		Percentage distribution				
All ages	100	100	100	100	100	
0-14 years	16.3	17.0	17.8	18.7	19.5	
15-44 years	42.5	41.0	40.0	39.6	39.5	
45-59 years	22.5	21.6	20.7	19.8	19.1	
60 years and over	18.7	20.4	21.5	21.9	21.9	
Crude vital rates		Per 1,000 population				
Birth rate	14.0	13.6	13.4	13.3	13.3	
Death rate	39.9	30.9	23.3	19.0	15.1	
Rate of natural increase	-25.9	-17.3	-10.9	-5.7	-1.8	

SOURCES: United Nations, *The Aging of Populations* ... (1956), p. 27; ———, *The Concept of a Stable Population* ... (1968), pp. 179-181.

population in the reproductive ages. The table shows that for any given level of the gross reproduction rate, the proportion of total population in the age group between 15 and 44 years declines as expectation of life at birth rises.<sup>96</sup>

84. As compared with the variations in crude death rates which can occur at a given level of fertility, the variations in crude birth rates among stable populations of the same mortality level are much greater. Table VIII.11 shows that crude death rates are generally much higher in low-fertility populations owing to the much higher proportion of older persons in the population. For example, in stable populations with a life expectancy at

birth of 70.2 years, the crude death rate is 15.1 where the gross reproduction rate is 1.0, but only 4.8 where the gross reproduction rate is 3.0. The percentage of persons 60 years and over in the two populations is 21.9 and 4.3, respectively. At higher mortality levels, however, the effects of differing age structures on crude death rates are not as great, since high infant and childhood death rates produce some compensating effect.<sup>97</sup> Thus, where expectation of life at birth is only 30 years, a stable population with a gross reproduction rate of 1.0 has a crude death rate of 39.9, whereas one with a gross reproduction rate of 3.0 has a crude death rate of 33.7. The relationships observed in these "stable" populations also hold true approximately in "quasi-stable" populations, which describe current conditions where mortality has declined.

<sup>96</sup> See also Coale and Zelnik, *New Estimates of Fertility* ... (1963), pp. 78, 80-82. The age distribution within the child-bearing span is also of some importance, since, given a set of age-specific birth rates, the crude birth rate will be higher in a population having the highest proportion at the peak ages of child-bearing. *Ibid.*, p. 70.

<sup>97</sup> See Coale, "Birth rates, death rates, and rates of growth ..." (1965), p. 261.

TABLE VIII.12. COMPARISON OF AGE DISTRIBUTION OF THE POPULATION AND CRUDE AND STANDARDIZED VITAL RATES IN THE UNITED KINGDOM (ENGLAND AND WALES), 1961, AND MEXICO, 1960

	United Kingdom (England and Wales) 1961	Mexico 1960
<i>Age (in years)</i>	<i>Percentage distribution</i>	
All ages .....	100.0	100.0

Death rate .....	4.8	11.3
Rate of natural increase .....	16.2	34.8

SOURCE: Compiled from Keyfitz and Flieger, *World Population ...* (1968), pp. 118-119, 536-537.

85. A way of illustrating the effect of age structure on the vital rates of actual populations is to calculate what those rates would be, given the age structure of another population. The results of such a standardization procedure for Mexico and the United Kingdom (England and Wales), drawn from a recent systematic analysis of demographic indicators for many countries of the world,<sup>98</sup> are presented in table VIII.12. The two populations selected are seen to differ greatly with respect to fertility and mortality levels. The greater effect of age structure on the crude death rate than on the crude birth rate is seen by comparing the actual birth and death rates of Mexico with those which would have resulted if the population had had the same age structure as that of the United Kingdom (England and Wales). Given the age structure of the latter, the Mexican death rate would have been 16.8 instead of 11.3, while the crude birth rate would have been 41.5 instead of 46.1. Since the substitution of the older population of England and Wales would have the effect of lowering the birth rate and raising the death rate, the rate of natural increase would be significantly lowered. Under such conditions, the crude rate of natural increase would be only 24.7 instead of the actual rate of 34.8.

<sup>98</sup> See Keyfitz and Flieger, *World Population ...* (1968).

86. The table also shows what the crude vital rates of England and Wales would be if that country had the same age structure as Mexico. With such an age structure, the crude birth rate would be 21.0 instead of 17.6, the crude death rate 4.8 instead of 11.8, and the crude rate of natural increase 16.2, instead of 5.8. When differences in age structure between the two countries are eliminated by standardization, no matter which population is used as the standard, the birth rates and rates of natural increase are found to move closer together and the death rates further apart. It can also be seen from the table that if Mexico's age-specific fertility and mortality rates were suddenly to drop to the levels of those in England and Wales, Mexico's age structure would cause the crude death rate to be lower and the crude birth rate and rate of natural increase to be higher than those prevailing in England and Wales.<sup>99</sup>

87. Investigating the limits of vital rates which might be attained in human populations, Coale found that a birth rate of 63 would result from the age structure of a stable population which combined the very high fertility schedule of the Cocos-Keeling Islands with very high mortality, viz. an expectation of life at birth of 20 years. A minimum crude death rate of about 2.5 was obtained in a hypothetical stable population which combined the Cocos Islands fertility schedule and a recent Swedish mortality schedule. The latter combination of high fertility and low mortality (gross reproduction rate 4.17 and expectation of life at birth of 75 years) would yield a rate of increase of about 5 per cent per year.<sup>100</sup>

88. The effect on vital rates of "transitional" age structures resulting from declining fertility is more complex. As shown by the data for Japan in table VIII.9 above, a fertility decline for a time produces a high proportion of persons in the reproductive ages. As a result, the decrease in the crude birth rate may be slowed down despite declining fertility rates. Moreover, since mortality risks are comparatively slight in the reproductive ages, such an age structure tends to accelerate the fall of the crude death rate. In general, during the transition from a fairly stable population with high fertility, the crude birth rate tends to be above, and the crude death rate below, the "intrinsic" rates that would eventually result from the current fertility and survival values. Therefore, the current rate of natural increase under these conditions tends to be above that which would eventually result from a continuation of the current fertility and mortality levels.

89. Examining the dynamics of age structure during demographic transition, Lorimer calculated the hypothetical populations which would result after thirty years from an initial population of high fertility and high mortality on two different assumptions: (A) if fertility remained constant while mortality declined substantially; and (B) if mortality declined as in hypothesis A and fertility

<sup>99</sup> A decline in Mexico's fertility would, of course, bring about a gradual change in that country's age structure, but it is certain that the rate of natural increase would remain for some decades at a higher level than that found in populations where fertility had long been low. The effect of transitional age structure on crude vital rates is discussed below.

<sup>100</sup> Coale, "Birth rates, death rates and rates of growth ..." (1965), pp. 263-264.

declined in such a way that the net reproduction rate remained constant. The results showed that, even under hypothesis B, the crude rate of natural increase rose throughout the projection period. Although the mortality assumptions in the two hypotheses were the same, the crude death rate declined more rapidly under the conditions of hypothesis B, owing to the declining proportion of infants in the population.<sup>101</sup>

90. In a recent analysis of the contribution of age composition to population growth, Preston showed that the present age structures of the populations of many high-fertility countries constitute an important factor in their growth, and that with fertility decline, as age structures become more middle-heavy, they will contribute even more to population growth in the future. He calculated that if age-specific fertility rates for Venezuela declined by 2 per cent annually, while mortality rates remained constant, the changing age distribution would be more favourable to growth for a period of seventy years than was the initial age distribution. Moreover, the age distribution's depressing effect on the crude death rate was found to be more important quantitatively than its stimulating effect on the crude birth rate in contributing to continued population growth.<sup>102</sup>

91. In addition to the direct influence that age structure exerts on crude vital rates, it also may create certain economic and social conditions which in turn affect mortality and fertility levels. The relative prevalence of younger or older persons in a population may give rise to optimistic or pessimistic attitudes which influence the frequencies of marriage and childbirth.<sup>103</sup> Disproportionate numbers of young adults unable to find productive employment, or of inadequately cared for older persons may cause such groups to be prone to nervous diseases, suicide, alcoholism, or drug addiction, thus tending to increase mortality rates. Excessive numbers of children may result in their neglect, with consequent higher infant mortality.

92. The availability of suitable mates for men and women of reproductive age obviously has a bearing on nuptiality and fertility. Where there have been heavy war casualties, for instance, the shortage of marriageable males may result in many women remaining unmarried, or marrying only late in life, with consequent depressing effects on fertility. Marriage opportunities for women in the Soviet Union, for example, were severely restricted as a result of heavy losses of young men in the two world wars.<sup>104</sup> Despite France's considerable losses of men in the First World War, Henry found that the proportion of women remaining single in the cohorts most affected

were not nearly as great as might have been expected. He attributed this to a reduction in the customary age difference between spouses, a higher than usual marriage rate among surviving males in the affected cohorts, and to immigration.<sup>105</sup>

93. In the period following the Second World War, significant reductions in the proportions of persons remaining single occurred in a number of European countries which had experienced no fighting on their soil. This trend was more evident for women than for men, owing to recent changes in the sex-age composition of the population which had been brought about by the cessation of large-scale emigration of males, the wearing off of the effects of the First World War, and the trend towards an older population.<sup>106</sup>

94. Since wives customarily are somewhat younger than their husbands, sharp fluctuations in the annual number of births can produce an imbalance in the numbers of men and women of marrying age some twenty years later. In the United States of America, for example, the long-term trend towards earlier marriage was reversed in the 1960s, and the proportion of single women marrying declined. These developments have been traced to disproportions between the numbers of men and women at the prime marriage ages, which appeared as the large cohort of female survivors of the post-war baby boom reached marriageable age.<sup>107</sup> Similar imbalances can be expected in rapidly growing populations, such as those of many developing countries having high fertility and sharply falling mortality. In Malaysia, where a considerable age difference exists between husbands and wives in all major ethnic groups, a surplus of marriageable females began to appear in the early 1960s, as the first female survivors of larger post-war birth cohorts reached marriageable age.<sup>108</sup> The opposite kind of imbalance will occur where there has been a rapid fertility decline, since cohorts of women reaching marriageable age will be too few in number to match the male cohorts with whom they would normally marry.

95. Various writers have been concerned with cyclical fluctuations in birth rates which occur over a period of twenty or twenty-five years and their consequent effects on the age structure.<sup>109</sup> For example, Lösch, writing mainly of German experience, noted that declines in the birth rate during war and subsequent increases in post-war periods create waves in the age structure which

<sup>109</sup> One author has applied complex time-series analysis to trends in the birth rate and their effect on age structure. Coale, "The use of Fourier analysis . . ." (1970).

result in new fluctuations in the birth rate when the affected cohorts reach the age of highest fertility.<sup>110</sup> Studying age data of the Burmese population at successive censuses, Bernardelli found evidence of "population waves", and observed the high frequencies of children which occurred when the female survivors of large cohorts reached reproductive age.<sup>111</sup> Other writers have examined the possibility of a reciprocal relationship between population and economic conditions, whereby fluctuations in age structure have economic effects which in turn influence the birth rate and set off a new round of demographic fluctuations. It has been pointed out that the slowdown of the rate of entry into the labour market in the United States of America during the 1940s, as a result of past demographic trends, was associated with a period of prosperity when job security and good prospects for advancement appear to have encouraged earlier marriage and an upswing in the birth rate. On the other hand, a quite different situation developed in the late 1950s as the survivors of larger birth cohorts began to reach working age and labour supply became more plentiful in relation to aggregate demand.<sup>112</sup>

96. The population's structure may also exert an influence on the rate of migration. For example, after the Second World War, shortages of persons in the productive adult ages in certain European countries led to an encouragement of immigration as a means of redressing structural imbalances in the population. France sought, through immigration, to attain a ratio of workers to dependants more similar to that in neighbouring countries.<sup>113</sup> The relative scarcity of young adult workers in the Federal Republic of Germany and their relative surplus in Italy<sup>114</sup> was undoubtedly a factor in the heavy migration from the latter country to the former in the post-war period.

#### D. Economic and social implications of sex and age structure

97. Throughout history, males and females of different ages have performed different functions in society, have been accorded different status, and have had different

needs. These differences vary widely from one society to another, and are sometimes reinforced by symbolic acts, such as the initiation ceremonies which may mark the transition from childhood to adulthood.<sup>115</sup> While some of these distinctions are biologically determined—for example, by the different reproductive roles of men and women—the economic, institutional and cultural patterns peculiar to each society constitute the predominant force. In the political realm, for example, women have generally played a negligible role,<sup>116</sup> but this appears to be the result of cultural conditioning, rather than of a "natural" disinclination on their part.<sup>117</sup> In certain societies the elderly have been accorded a privileged status because of the knowledge, wisdom, and judgement gained through long experience,<sup>118</sup> but this status has been declining in many parts of the world, while what has been termed a "youth culture" has recently emerged in a number of developed countries.

98. A society's sex and age structure assumes particular importance for the functioning of the economy, since these two attributes constitute the main criteria for determining the division of labour. Taeuber has pointed out that males between the ages of 15 and 59 years of age bear the main responsibility for maintenance of the family and engage in some form of productive work. The activities of women at these ages are more diverse, since they may include childbearing, childrearing and home-making, as well as economic activity.<sup>119</sup> Boserup, on the other hand, has emphasized the very different economic roles played by women in different parts of the world's developing regions, calling attention to the fact that in certain societies it is women rather than men who are chiefly responsible for food production, and what are considered "natural" roles for men and women in one society may be quite different in another society.<sup>120</sup>

99. In view of the diversity of roles and needs, as established in each society, variations in the composition of a population by sex and age can have far-reaching economic, social and political implications. The study of these implications, which requires the expertise of both demographers and anthropologists, has as yet received insufficient attention.

<sup>110</sup> Lösch, *Bevölkerungswellen und Wechsellagen* (1936); and his "Population cycles as a cause . . ." (1937).

<sup>111</sup> Bernardelli, "Population waves" (1941).

<sup>112</sup> Grauman, "Comment . . ." (1960), pp. 281-282; Easterlin, "Economic-demographic interactions and long swings . . ." (1966), pp. 1083-1087. Easterlin's detailed analysis of demographic and economic trends in the United States of America led him to conclude that it was the concurrence of several circumstances—an expansion in the economy, restricted immigration and a low rate of labour force entry—that created exceptionally favourable labour market conditions in the late 1940s and 1950s and led to higher fertility. See his *Population, Labor Force and Long Swings* . . . (1968), particularly pp. 108-109. The author also implied that age composition of the population might have some bearing on cyclical movements in migration. He stated that "Labor demand conditions in the United States were the systematic factor initiating an upsurge [in immigration], though the amplitude and composition of the response depended upon the particular supply conditions prevailing at the time." *Ibid.*, pp. 35-36.

<sup>113</sup> See Sauvy, "Besoins et possibilités . . ." (1950), pp. 216-218.

<sup>114</sup> See the comparisons given in Sauvy, "La population de l'Europe occidentale . . ." (1951), p. 387.

<sup>115</sup> See Piddington, *An Introduction to Social Anthropology* (1952), vol. 1, p. 175.

<sup>116</sup> It may be noted that in mankind's long history, women have received the right to vote relatively recently and that this right is not yet universal. See United Nations, Commission on the Status of Women, *Constitutions, Electoral Laws and Other Legal Instruments* . . . (1968).

<sup>117</sup> On the strong societal forces which have shaped women's "nature", see Mill, *The Subjection of Women* (1869, 1970 ed.).

<sup>118</sup> In many primitive societies, important community affairs are regulated by councils of elders, a system which has been termed "gerontocracy". Piddington, *An Introduction to Social Anthropology* (1952), vol. 1, p. 75. See also Lips, "Government" (1938), pp. 496-497. It has been pointed out, however, that treatment of the aged varies among primitive societies and, in some, old age is looked down upon. Reichard, "Social life" (1938), p. 422.

<sup>119</sup> Taeuber, "Population growth in underdeveloped areas" (1963), p. 39.

<sup>120</sup> Boserup, *Women's Role in Economic Development* (1970), pp. 15-16; see also Lowie, "Subsistence" (1938), p. 319; Bunzel, "The economic organization of primitive peoples" (1938), pp. 336, 369 ff.

TABLE VIII.13. MAIN FUNCTIONAL AGE GROUPS FOR MAJOR AREAS OF THE WORLD, 1950 AND 1965

	World total	Developing regions	More developed regions	Africa	East Asia	South Asia	Europe (excluding the USSR)	Latin America	Northern America	Oceania	USSR
Total population (millions)											
1950 .....	2,486	1,628	858	217	657	698	392	162	166	13	180

SOURCE: Compiled from data in United Nations, *World Population Prospects as Assessed in 1968* (to be issued as a United Nations publication).

Note: Because of rounding, totals are not in all cases the exact sum of the parts.

100. For convenience, the groups or contingents which fulfil particular functions are usually delimited by age (as in the case of the working-age males referred to above), although there is far from complete coincidence between the age limits set for a given functional contingent and the population which actually performs the function in question. For example, the size of the school-age population in developing countries may far exceed the actual number of persons enrolled in schools, partly because of a shortage of educational facilities. Populations of working age may include large numbers not in the work force, particularly women, while excluding many children and older persons who work. Even where the age limits of a contingent are biologically defined, as in the case of women

of reproductive age, actual exposure to the risks of child-bearing are regulated by cultural norms affecting sexual behaviour and age at marriage. The functional contingents discussed below should therefore be viewed as rough approximations of the potential of given segments of a society to fulfil certain roles.

#### 1. DYNAMICS OF MAIN FUNCTIONAL GROUPS

101. A distribution of the population in each region of the world by broad age groups was presented earlier in the chapter. Table VIII.13 gives information on more detailed age contingents and changes in their size from 1950 to 1965. The contingents shown in the table are the

following: pre-school population, school-age population, working-age population, old-age population, and females of reproductive age. The age boundaries of these contingents are not similarly defined in all societies. For example, different conditions may prevail from one country to another with respect to customary working ages. Various additional groups may also be identified, such as the youth population, sometimes taken to be the population between the ages of 15 and 24, males of military age, or the population having legal responsibility, or being of voting age, e.g. persons 18 years of age and over in some societies.<sup>121</sup>

102. The table shows that during the decade and a half between 1950 and 1965, the different contingents were growing at varying rates, and this variation was much more marked in the developed than in the developing regions. In the developed regions, total population grew by a little more than one fifth during this period. The aging trend is apparent from the 43 per cent increase in the number of persons aged 65 years and over. The working-age contingent increased by 18 per cent, and the female contingent of reproductive age by 12 per cent. While the pre-school population grew by only 12 per cent, the school-age population showed a growth of 27 per cent, as the large cohorts from the post-war baby boom moved into this group. The greater uniformity of growth rates of the different contingents in the developing regions is reflected in a fairly stable age structure. Thus, the pre-school contingent, working-age population, and women of reproductive age all increased at about the same rate as the population as a whole (38 per cent). A somewhat higher than average percentage increase (45 per cent) is shown, however, for the school-age contingent.

103. The table shows a considerable contrast between East Asia and South Asia in the growth rates of different contingents. In East Asia the pre-school population grew by only 12 per cent, as compared with an increase of 30 per cent for the population as a whole. This slower growth rate of the pre-school group reflects the more moderate level of fertility estimated for China in the 1960s, and the well-documented decline in Japan. In the latter country, between 1950 and 1965, the number of pre-school children was reduced by about one fourth. In South Asia, on the other hand, where fertility has not yet begun to decline in the populous countries, both the pre-school and school-age contingents have been increasing at a considerably more rapid rate than the rest of the

population. As pointed out earlier, mortality decline in its initial stages is likely to affect the younger age groups disproportionately, resulting in such a pattern.

104. Of crucial importance for determining needs for educational facilities and teachers are the size and growth rate of the population of school age. This group of 5 to 14-year-olds makes up about one quarter of the total population in the developing regions, and about one fifth in most of the developed regions, although somewhat less in Europe. It is noteworthy that the expansion of numbers in this group between 1950 and 1965 was more rapid in Northern America and Oceania (62 per cent and 65 per cent, respectively) than in any of the developing regions, despite the latter's higher growth rates of total population. In the United States, the unprecedented numbers of children and adolescents resulting from the post-war baby boom were causing certain strains on the economy by the 1960s, and double-shift and oversize school classes had become commonplace.<sup>122</sup> In Europe, the school-age population showed a more moderate growth rate of 17 per cent between 1950 and 1965. In contrast to Northern America and Oceania, where high post-war birth rates were sustained for a considerable period, in Europe the baby boom was pronounced only in the immediate post-war years up to 1950; by 1965 the affected cohorts had thus passed into the 15-19 age group.

105. Very large increases in the school-age population were recorded in Latin America (59 per cent), South Asia (50 per cent), and Africa (42 per cent). The magnitude of the problem in one country—India—is illustrated by the fact that the number of children in primary, middle and secondary schools was expected to increase by more than 20 million—from 43.5 to 64.0 million—and the number of such schools to increase by about 96,000 during the Third Five-Year Plan period, 1961-1966.<sup>123</sup>

106. As discussed in chapter IX, section A, trends in the numbers of persons aged 15-64 years have much bearing on the size of the labour force and changes therein. For reasons stated earlier, the numbers in this age group cannot, of course, be equated with the economically active population. Nevertheless, the rate at which the working-age population is expanding gives a rough indication of the rate at which new jobs will have to be provided by the economy, if rising unemployment is to be prevented.<sup>124</sup>

107. The table shows that between 1950 and 1965, the working-age population—both in the developed and developing regions—was growing at a slightly lower rate than the total population. This pattern is also seen in each of the major regions, with the exception of East Asia. The largest percentage increase in the working-age

<sup>121</sup> In studies of the sex and age structure in Yugoslavia, for example, the following are among the contingents which have been singled out: pre-school children (0-6 years old); school-age children (7-14 years old); working-age population (15-64 years for men, 15-59 for women); population past working age; adult population (18 years and over); women of reproductive age (15-44 or 15-49 years), and those which contribute the most to total fertility (20-34 years). See Macura, *Stanovništvo i radna snaga* . . . (1958), pp. 114-117; Tasić, "Dugoročne promene starosne . . ." (1963); Todorović, "Buduće promene u starosnoj . . ." (1968). In an analysis of projected population trends in major developing countries, Taeuber identified the following groups: children in elementary school ages (5-14 years); youth aged 15-19 years and population in the productive ages (15-59 years). Taeuber, "Population growth in underdeveloped areas" (1963).

<sup>122</sup> Bogue, "Population growth in the United States" (1963), p. 77.

<sup>123</sup> India, Planning Commission, *Third Five Year Plan* (1961), pp. 573-577.

<sup>124</sup> Generally, the rate of growth of the active population has been found to be a little lower than that of the working-age population in view of the tendency for activity rates in the marginal age groups to decline over time. See chapter IX, section A.

contingent shown for any region is that for Latin America—46 per cent. The economic absorption of such a huge increase in the productive segments of the population poses an extremely formidable task, making the problem of unemployment and underemployment one of the dominant features of the Latin American economies in the 1960s.<sup>125</sup> Similar problems confront the other developing regions as well, though the rate of expansion of the working-age population was not quite so rapid.

108. On the whole, the old-age population has been growing at a more rapid rate in the world's developed regions than in the developing regions—43 per cent in the former and 27 per cent in the latter, between 1950 and 1965. While the percentage increases in the old-age population were greater in Northern America, the Soviet Union and in Oceania than in Europe, the absolute increase in the last-named region was particularly impressive. Numbering 34 million in 1950, the 65 and over group had increased by 12 million, to 46 million in 1965.

109. The size of the female population in the reproductive age influences the crude birth rate, and hence the rate of population growth. In 1965, the range in the proportion that women of reproductive age constituted of total population in the different regions was not very wide—from about 20 per cent in Northern America and Oceania to 23 per cent in the Soviet Union, the latter percentage reflecting the large deficit of males in the population referred to previously. Between 1950 and 1965 the number of women of reproductive age was growing at a slow rate in Europe, Northern America and the USSR, but very rapidly in the developing regions. In Latin America, this contingent increased by 45 per cent. Such rapid growth in the numbers of women in the fertile ages generates a powerful momentum for increase in the absolute number of births, even in the face of declining fertility rates.<sup>126</sup> Other developing regions also showed large percentage increases in this contingent: about 40 per cent in Africa and about 33 per cent in Asia.

## 2. GENERAL IMPLICATIONS

110. Many of the important economic and social implications of a population's sex and age structure are discussed in detail in later chapters. It has been seen above that age structure has a considerable bearing on the ratio of producers to the total number among whom the national product is distributed. Other things being equal, a population which has a higher ratio of persons in the productive age groups will have a higher *per capita* output, greater savings and larger investments available for developmental purposes. Under these conditions, less

will be spent *per capita* on primary education, housing and "social overhead". Higher *per capita* product is correlated with higher *per capita* consumption and, at least in the early stages of development, with higher productivity of the labour force, resulting in part from better nutrition and work incentives.<sup>127</sup>

111. The needs for educational facilities and teaching personnel are obviously closely connected with the current and projected numbers of population of school age. The larger the proportion of school-age children in the population, the greater is the proportion of national income which must be spent to provide education at a given standard. The high annual investment in education which is required to prevent a deterioration in standards makes it difficult for developing countries with rapidly increasing child populations to provide adequate educational progress.<sup>128</sup> While a change to an older age structure may reduce the proportion of expenditures for educational facilities, the relative needs for other types of social services are increased (see the discussion of implications of an aging population below).

112. The age structure of a population has an impact on consumption levels and patterns, since people at different ages have different needs.<sup>129</sup> Savings, too, may be affected, but these effects are not easily assessed. Generally speaking, findings of studies on the effect of age structure upon savings suggest that the greatest savings are likely to be achieved in a population having a relatively large proportion of adults of working age. The relationships between age structure, consumption levels and patterns, and savings, are examined in more detail in chapter XIII, section A.

113. The age structure of the population, through its effect on the composition of families, may considerably affect housing needs. The numbers of families of various sizes and the numbers with children of various ages clearly help to determine the need for different types of housing, since in a young population, where average family size is large, the relative requirements for houses as compared to apartments will be greater than in an older population where families are of smaller size. A discussion of the role played by age structure in influencing household size and composition and housing needs is contained in chapter X, particularly section E.

<sup>125</sup> United Nations, Economic Commission for Latin America, *Economic Survey of Latin America, 1968* (1970), pp. 21-28. See also El-Badry, "Perspectiva de la población Latinoamericana ..." (1971); Taeuber, "Population growth in underdeveloped areas" (1963), pp. 39-40.

<sup>126</sup> The continued rapid increase of women of childbearing age in the developing countries would result in a 50 per cent increase in the number of births in the late 1970s, compared with the early 1960s, even if fertility levels should remain unchanged. Taeuber, "Population growth in underdeveloped areas" (1963), p. 40.

<sup>127</sup> Coale, "Population and economic development" (1963), pp. 60-61. It has been estimated that the changes in age structure in India which would result from a 50 per cent reduction in the rate of childbearing beginning in 1956 would add about 40 per cent to the income per consumer after thirty years, above that which could be expected if fertility rates remained unchanged. Coale and Hoover, *Population Growth and Economic Development ...* (1958), pp. 272, 284, 291.

<sup>128</sup> See, for example, Coale and Hoover, *Population Growth and Economic Development ...* (1958), pp. 248-249; Lambert, "Croissance démographique et instruction ..." (1960).

<sup>129</sup> For example, nutritional needs (e.g. calorie requirements) vary with sex and age. See Sukhatme, "The world's hunger and future needs ..." (1961), p. 472.

### 3. IMPLICATIONS OF AN AGING POPULATION

114. Aging may concern an individual or a population, these being distinct concepts.<sup>130</sup> An individual ages as his chronological age increases, passing between conception and death through an orderly sequence of irreversible stages which include infancy, childhood, adolescence, adulthood and old age.<sup>131</sup> The aging of human populations is a much more complex notion, and there is no unanimously held definition of this concept. Unlike the case of the individual, a population does not necessarily age over time, but may remain unchanged or even grow younger.<sup>132</sup>

115. Generally speaking, the aging of a population consists of an increase in the proportion of persons defined as "old" in the population.<sup>133</sup> Conversely, it can be said that a population grows younger when the proportion of young persons increases. Actually, both processes, i.e., aging and rejuvenation as defined above, can occur simultaneously. It is sometimes said that a population is aging at the apex when the proportion of old persons is increasing and that it is aging at the base when the proportion of young persons is declining.<sup>134</sup>

116. As seen in section A, the populations of the industrialized countries have aged considerably during the past century, mainly as a result of declining fertility. As the countries most affected by this process are those of Western Europe, Northern America and Oceania, the problem of aging, far from being universal, is confined to a relatively small segment of the world's population. This progressive aging has had substantial repercussions on the economic, political and social life of nations, and has given rise to a special branch of research generally referred to as social gerontology, and concerned with the non-biological problems of aging.<sup>135</sup> Some of the major implications of the aging phenomenon, based on selected studies from the vast literature on this subject, are summarized below.

117. It has often been argued that aging of the population tends to depress the level of living in the highly industrialized countries. One of the ways aging may exert an influence is through its effect on the ratio of dependants to productive elements in the population. As shown in section A, until recently the aging of population in most of these countries has been such as to reduce the dependency ratio, since the relative number of children

has declined faster than the relative number of persons too old to work has increased. The lower dependency ratio which aging thus made possible is estimated to have contributed to rising levels of living in many of the industrialized countries.<sup>136</sup> Recent decades, however, have seen a rise in the total dependency ratio, as the proportion of older persons in the population has risen rapidly, and the proportion of children has increased as a result of the post-war recovery in the birth rate.

118. The shifting ratio of child to aged dependants is also of importance, since the cost of providing for a dependent child may be different from that for an aged dependant.<sup>137</sup> A few studies have attempted to estimate the relative costs of supporting juvenile and aged persons, as well as working-age adults. Burgdörfer found, for example, that the cost of maintaining a child in relation to that of an adult and an old person was in the ratio of 3.5 to 7 to 6 in Germany.<sup>138</sup> In France, the costs of maintaining persons in various age groups in 1966 have been estimated as follows: 16,400 francs for persons below 18 years of age, 32,600 francs for persons 18-65 years of age, and 22,500 francs for those over 65 years.<sup>139</sup> In Great Britain it was estimated for the financial year 1952-1953 that the cost of state social services for maintaining a child under 15 years of age was £34.9, whereas the cost of maintaining an old person was £69.6.<sup>140</sup> A United Nations study reported that the needs of a child and an elderly person were roughly the same—70 per cent of those of an adult.<sup>141</sup>

119. Not only the relative size of the working population, but also the efficiency of workers may be affected by the aging of the population and the concomitant aging of the labour force.<sup>142</sup> Many writers have expressed the view that a relatively young labour force is more efficient than an older one, since young people excel in such qualities as physical strength, energy, enthusiasm, adaptability and the capacity to learn new things and to innovate.<sup>143</sup> On the other hand, wisdom, experience, patience, breadth of view, stability and judgement are qualities more prevalent among older than among younger

<sup>130</sup> Spengler, "The aging of individuals and populations ..." (1966), pp. 44-47.

<sup>131</sup> See Anderson, "Psychological research on changes and transformations ..." (1964). Biological and psychological changes are inherent in the individual's passage from infancy to old age. Kiser, "The aging of human populations ..." (1962), p. 18. These changes have repercussions on the individual's economic activity and his social behaviour. United Nations, *The Aging of Populations* ... (1956), p. 1.

<sup>132</sup> Kiser, "The aging of human populations ..." (1962), p. 18.

<sup>135</sup> Tibbitts, "Origin, scope, and fields of social gerontology" (1960).

<sup>136</sup> The United Kingdom Population Commission estimated that *per capita* national income in the middle of the twentieth century would have been about one eighth lower if the nineteenth century age structure still existed. United Kingdom, Royal Commission on Population, *Report* (1949), p. 112.

<sup>137</sup> A discussion of several studies on this subject can be found in Stassart, *Les avantages et les inconvénients* ... (1965), pp. 60 ff.

<sup>138</sup> Burgdörfer, *Volk ohne Jugend* ... (1932), pp. 304-305.

<sup>139</sup> See Sauvy, *Théorie générale de la population*, vol. 2 ... (1966), pp. 60-61. These are adjusted figures, based on estimates made in 1950 by the Commission supérieure des conventions collectives.

<sup>140</sup> Paish and Peacock, "Economics of dependence (1952-82)" (1954), p. 289. These costs were expected to increase as a larger proportion of the aged became eligible for retirement, and other social benefits became more liberal. *Ibid.*, p. 290.

<sup>141</sup> United Nations, *The Aging of Populations* ... (1956), p. 61.

<sup>142</sup> Robbins, "Notes on some probable consequences ..." (1929), pp. 75-76; Daric, *Veillissement de la population* ... (1948), p. 35. Daric also said, however (p. 140), that a sizable proportion of older workers still have a higher efficiency and productivity than is found among younger workers.

<sup>143</sup> See, for example, United Kingdom, Royal Commission on Population, *Report* (1949), p. 121.

workers,<sup>144</sup> but there is little agreement as to whether such qualities may compensate in considerable measure for the loss of youth.<sup>145</sup> The British Population Commission contended that a reduction in the proportion of younger workers had not led to lowered efficiency since there remained a greater number of people possessing a high degree of strength than there were jobs demanding such strength.<sup>146</sup> Notestein and his colleagues also emphasized that productivity was as much a function of training and experience as of vigour.<sup>147</sup> The view has been expressed, however, that the positive qualities associated with advancing age are no longer considered as important as formerly.<sup>148</sup> Studies of the relative efficiency of workers of different ages in various types of jobs are as yet inadequate to resolve the question of the effect of aging on the efficiency of the labour force.<sup>149</sup>

120. Some authors believe that the efficiency, not only of the workers, but also of their machines, tools and other capital equipment tends to decline as population ages. This is thought to occur because the need for renewing equipment is not felt so strongly in a country where the average age is relatively high, as in one with a younger population.<sup>150</sup>

121. The flexibility of the economically active population is also believed to be affected by the aging process. It is generally concluded that younger men and women are the most mobile and adaptable groups in the population and that, as a consequence, a decline in their relative numbers in the labour force will result in less flexibility, other things being equal. Older workers have been shown to be less likely to migrate in search of better employment opportunities than are younger workers;<sup>151</sup> moreover, they are less occupationally mobile, since having acquired specialized skills, they often cannot easily be retrained

for other jobs.<sup>152</sup> That older workers are less adaptable has been demonstrated by statistics which show longer durations of unemployment for workers past middle age than for younger workers.<sup>153</sup> Thus, aging of the labour force may increase the risk of structural unemployment, though its precise effect in this respect has not been measured.<sup>154</sup>

122. As discussed in chapter XIII, section A, many authors believe that aging of the population tends to lower the rate of saving, since older persons typically live on accumulated savings and the community incurs large expenditures for services to them. It has also been suggested that the aging of a population over a long period may have a substantial effect on its income structure. In the United States a systematic increase in inequality of income with age has been found to exist, with the 65 years and over group displaying the greatest degree of income concentration.<sup>155</sup> Additional statistical analyses of the relation of savings, expenditures and income to age in various countries are needed in order to verify existing hypotheses.

123. Some writers who have concerned themselves with the implications of an aging population place great emphasis on the possibility that economic, cultural and political progress may be retarded where the population is composed of a relatively large proportion of aged persons. They maintain that the management of economic undertakings is less courageous and less enterprising. They believe also that the character of leadership, not only in the economic but also in political and other fields, becomes more conservative as the average age of the leaders rises, and thus, that society tends to lose some of its dynamism.<sup>156</sup> The British Population Commission concluded that not only technical efficiency and economic welfare, but also intellectual and artistic achievement may suffer in an aging society, and that comparisons between

<sup>144</sup> *Ibid.*; see also Spengler, "Some effects of changes in the age composition . . ." (1941), pp. 169-170.

<sup>145</sup> The importance of factors other than chronological age in determining productive performance has been noted by many writers. See, for example, Davis, "Population and welfare in industrial societies" (1962), p. 20; Lehman, *Age and Achievement* (1953); Anderson, "The use of time and energy" (1959).

<sup>146</sup> United Kingdom, Royal Commission on Population, *Report* (1949), p. 119.

<sup>147</sup> Notestein *et al.*, *The Future Population of Europe and the Soviet Union* . . . (1944), p. 130. Reddaway noted that even if some older workers are not fully efficient, neither are young boys and learners. Reddaway, *The Economics of a Declining Population* (1939), pp. 143-144.

<sup>148</sup> See Spengler, "The aging of individuals and populations . . ." (1966), p. 62.

<sup>149</sup> As early as 1940, Myrdal had called attention to the need for empirical studies to ascertain the productivity of workers in different age groups. See his *Population: a Problem for Democracy* (1940), p. 145. Based on a comprehensive summary of studies on the effects of aging on work performance, McFarland and O'Doherty concluded that it is difficult to find dependable criteria for measuring such effects on industrial efficiency. However, measures of productivity, absenteeism and sickness, accidents, and labour turnover were found, tentatively, to be little affected by aging. McFarland and O'Doherty, "Work and occupational skills" (1959).

<sup>150</sup> Darc, *Vieillessement de la population* . . . (1948), pp. 32-33. See also Sauvy, "Social and economic consequences . . ." (1948), p. 116.

<sup>151</sup> Moore, "The aged in industrial societies" (1950); Brennan, Taft and Schupack, *The Economics of Age* (1967), pp. 115-116.

<sup>152</sup> Thoma, "Ageing and problems of adjustment" (1963), pp. 369-370; Durand, *The Labor Force in the United States* . . . (1948), p. 41; Dereymaeker, "Interaction entre l'économie . . ." (1946).

<sup>153</sup> In 1957, in the United States, for example, the average duration of unemployment for men 65 and over was nineteen weeks, compared with only about eight weeks for teen-agers. Gordon, "Work and patterns of retirement" (1961), p. 19. These patterns are also partly due to age discrimination in hiring. *Ibid.*

<sup>154</sup> The theoretical problem of productivity and employment of older workers is dealt with at length in Kaufmann, *Die Überalterung: Ursachen, Verlauf, wirtschaftliche* . . . (1960), pp. 268-304.

<sup>155</sup> Fisher, "Income, spending, and saving patterns . . ." (1952), pp. 82-84, 101-102. See also Sheldon, *The Older Population of the United States* (1958), p. 132.

<sup>156</sup> See Boverat, *Le vieillissement de la population* (1946), pp. 128-133; Spengler, "Some effects of changes . . ." (1941), pp. 159, 170-171; Sauvy, *Théorie générale de la population*, vol. 2 . . . (1966), p. 71; Kaufmann, *Die Überalterung: Ursachen, Verlauf, wirtschaftliche* . . . (1960), pp. 492-499. A tendency for people to pass through several political stages from radical to reactionary as they grow old has been noted. Friedrich, *Constitutional Government and Democracy* . . . (1950), p. 421. Among the systematic age-related changes found in the political orientation of the American electorate were the oft-noted movement towards conservatism, and a steady increase in the strength of political party attachments with increased age. Campbell *et al.*, *The American Voter* (1960), pp. 160-167, 210-211; Campbell, "Social and psychological determinants of voting behavior" (1962).

countries have suggested that average age may have an important effect on the spirit of the community.<sup>157</sup> Furthermore, an aging population is thought to produce certain unfavourable effects on individuals, such as an increased sense of frustration among the young arising from greater competition for promotion, and an increased rigidity and negative attitude towards life with advancing age.<sup>158</sup> Other authors have taken a less pessimistic view of the aging of population as a factor retarding progress, and have stressed the role of non-demographic factors.<sup>159</sup>

124. Trends in aging also have important implications for social security provisions, health services, provision of facilities for the use of leisure, and other services to older persons. Demographic trends in industrialized countries have furnished an important stimulus to the establishment of social security schemes and the liberalization of old-age benefits. The growing proportion of elderly persons in the electorate has led to greater political pressure for higher benefits and more liberal conditions of eligibility.<sup>160</sup> Public expenditures for benefits to the aged have risen not only as a result of the rising proportion of aged persons in the population, but also because of rising *per capita* costs. The declining proportion of child dependants has not provided compensation, since the State normally assumes a much smaller share of financial responsibility for the support of children than for the aged.<sup>161</sup> While the family may be an efficient social institution for the care of dependent children, it cannot, under modern conditions, provide adequate security for older persons, since an increasing proportion of elderly people are childless, or live far away from their children.<sup>162</sup> The heavy budgetary burden imposed on the community by increasing needs for old-age pensions may necessitate restriction of allotments for new developments in other fields,<sup>163</sup> or modifications in the pension schemes.<sup>164</sup>

125. In addition to numerous studies concerned with the income needs and economic status of the aged,<sup>165</sup> a growing body of literature exists on problems associated with providing various services and facilities on behalf of the aged,<sup>166</sup> and the requirements for public expenditures which they entail. Foremost among these needs are adequate housing accommodations, health and medical care, including hospital care, social services and leisure-time facilities. The process of aging also tends to create psychological and social problems for the individual and society. Aging persons typically experience increasing isolation from family ties and personal and social relationships, and often suffer psychological effects from abrupt retirement at a fixed age.<sup>167</sup>

126. Owing to the rapid growth of the aged population and the progressive breakdown of the extended family which accompanied industrialization, the provision of suitable housing for the aged has become a matter for growing public concern. Since the limited financial means of a large proportion of older people precludes their finding suitable living accommodations, State activity, taking the form of subsidization of housing programmes, and rent supplements and allowances, has been stimulated. While a number of countries have made important strides in this area, the provision of housing which suits the physical needs of the aged, as well as their ability to pay, remains a major problem.<sup>168</sup>

---

that the provision of old-age pensions will become an unbearable burden. Bogue, *The Population of the United States* ... (1959), p. 103.

<sup>159</sup> Fourastié, for example, has emphasized the effect on society when large proportions of people live long enough to complete higher education, and can look forward to many years of creative life. Fourastié, "De la vie traditionnelle à la vie 'tertiaire'" (1959). See also Durand, "The trend toward an older population" (1945), p. 150; Brüscheiler, "Vorherrschaft der Alten?" (1941), pp. 6-10.

<sup>160</sup> See, for example, Borrie, *Population Trends and Policies* ... (1948), pp. 159-160; Durand, "The trend toward an older population" (1945), p. 149; Ammann, "Die Auswirkung der Überalterung ..." (1938); Tibbitts, "Politics of aging: pressure for change" (1962). For a case study of an old-age pressure group in California, see Pinner, Jacobs and Selznick, *Old Age and Political Behavior* ... (1959).

<sup>161</sup> Sauvy, *Richesse et population* (1944), chap. 9; Fromont, *Démographie économique* ... (1947), p. 145.

<sup>162</sup> Sauvy, "Social and economic consequences ..." (1948), pp. 118-119.

<sup>163</sup> Daric, *Viellissement de la population* ... (1948), pp. 37-39; United Kingdom, Royal Commission on Population, *Report* (1949), p. 116. Bogue has pointed out, however, that under a social security system such as that in the United States of America, which requires workers to pay a contribution to their future pension, it is unlikely

127. Increasing longevity also presents a challenge in the sphere of health and medical services, as the greater health care needs of the aged, compared with other segments of the population, are coupled with soaring medical costs. In countries with State-sponsored medical care programmes, such as the socialist countries and some Western countries, the costs of medical care for the aged represent a heavy public financial burden. In countries where this burden falls primarily upon the individual, the aged often simply do not receive the medical care which they require.<sup>169</sup>

128. As a person ages, the number of roles which he plays diminishes at the same time that the extent of his interaction with others also shrinks and changes in quality. This process of disengagement, as it has been termed by some writers, has been defined as "an inevitable process in which many of the relationships between a person and other members of society are severed, and those remaining are altered in quality".<sup>170</sup> The disengage-

<sup>169</sup> On health problems of the aged, see, for example, Rosen, "Health programs for an aging population" (1960); Peterson and Peterson, "The health of the aging" (1960); Lissitz, "Evolving a pattern of financing ..." (1962); Paillat and Wibaux, *Conditions de vie et besoins des personnes âgées en France, vol. 1* ... (1969), pp. 37-94.

<sup>170</sup> Cumming and Henry, *Growing Old* ... (1961), p. 211. See also Cumming, "Further thoughts on the theory of disengagement" (1963).

ment process may be initiated by the individual, the society, or by both simultaneously, and is often more abrupt for men than for women. It can result in crisis and loss of morale for the individual, unless suitable alternative roles are available to fill the voids.<sup>171</sup> The associated factors of work, retirement, leisure and morale, as they relate to older persons have, accordingly, been treated in numerous studies.<sup>172</sup>

129. With the trends in aging of the population expected to continue in most parts of the world, the basic problems which aging presents both for society at large and for the individual, some of which have been touched upon above, call not only for additional studies, but also for practicable and satisfactory solutions.

<sup>171</sup> Cumming and Henry, *Growing Old* ... (1961), chap. 12. Parsons believes that the older age groups can provide the necessary element of stability in a rapidly changing society. See his "The cultural background of today's aged" (1962), pp. 13-15.

<sup>172</sup> See, for example, Kleemeier, ed., *Aging and Leisure* ... (1961); Kaplan, "The uses of leisure" (1960); Donahue, Orbach and Pollack, "Retirement: the emerging social pattern" (1960); Dumazedier and Ripert, "Retirement and leisure" (1963); Burgess, "Aging in Western culture" (1960); Ter Veld, "Patterns of leisure-time behavior ..." (1962); Havighurst, "The nature and values of meaningful free-time activity" (1962); Simpson and McKinney, eds., *Social Aspects of Aging* (1966).

## DEMOGRAPHIC ASPECTS OF MANPOWER

1. Work and production are intimately linked to man's existence and survival. Throughout all stages of civilization and development—be it the food-gathering, hunting, agricultural or industrial stages—man has had to exert himself to provide for his subsistence and the needs and requirements of society. With the passage of time and cultures, the nature of work has been changed fundamentally. The growth of knowledge and technology, the increasing specialization and division of labour, and the transformation of economic functions and of society itself have enlarged man's needs, as well as his capacity to produce, thus creating changes in the volume, quality and character of his work.

2. Different disciplines have different interpretations of the economic functions of the population owing to their different frames of reference and diverse approaches to the understanding of human society. Demography, as a science of human population, has developed its own interpretation, based on the economists' distinction between producers and consumers. This interpretation considers the economically active population, or labour force,<sup>1</sup> as a demographically identifiable category which can be distinguished from other population segments by the fact that its function is to produce the goods and services needed to satisfy the requirements of the whole population. Within this conceptual framework, the economically active population is not only an economic category, but a demographic one as well. This means that the research apparatus of demography can be applied to manpower studies. In actual practice, however, many difficulties arise in attempting to distinguish the economically active from the inactive population, and precise concepts and definitions for measuring these categories have become a necessity.

3. The labour force includes, in addition to persons who work for wages or salaries (in civilian jobs or in the armed forces), own-account workers and employers who work for profit and persons who, like the farmer's son, assist without pay in a familial income-producing enterprise. According to recommended international definitions, unemployed persons seeking paid jobs are considered as members of the labour force, as well as

those actually employed.<sup>2</sup> On the other hand, the labour force does not include persons engaged in activities which do not produce income. Thus women engaged only in domestic work in their own homes are not counted as members of the labour force, as the services and goods which they produce are not considered as income, although the value of these services and goods represents an important part of the total product of a nation.<sup>3</sup>

4. The size of a country's labour force and its proportion to the population have evident bearings on the productive capacity of the economy and the level of income per head that can be attained, although the productivity of labour and the rates of unemployment and underemployment are also, obviously, factors of major importance. As a measure of the quantity of labour supply, the number of persons in the labour force is only a first approximation. A more satisfactory measure requires consideration of such aspects as the length of the working week, the numbers of labour force members available only for part-time or seasonal work, and the annual turnover of persons entering and leaving the labour force.<sup>4</sup> The qualities of labour supply are still more

<sup>2</sup> Some analyses have been based on the civilian labour force (that is, excluding the armed forces) or the civilian employed labour force (that is, also excluding the unemployed). See Bloch and Praderie, *La population active* . . . (1966), pp. 27-28. In some of the literature, particularly in socialist countries, "labour force" has a more restricted meaning in that it excludes the unemployed. For further discussion of this question, see Rajkiewicz, "Z problematyki badań nad . . ." (1963).

<sup>3</sup> A comprehensive view of a nation's human resources and their utilization for productive purposes would take into account not only the unpaid work of housewives but also other productive activities which do not yield income, such as "do-it-yourself" production and volunteer work. Data on inputs of working time into such activities and on the value of the products are not widely available. Estimates for Belgium are given in Chaput-Auquier, "La valeur économique du travail ménager" (1959); for Great Britain, Clark, "The economics of house-work" (1958); for the United States of America, Morgan, Sirageldin and Baerwaldt, *Productive Americans* (1966). On time-inputs of French married women into gainful and other activities, see Girard, "Le budget-temps de la femme mariée dans les agglomérations urbaines" (1958); Girard and Bastide, "Le budget-temps de la femme mariée à la campagne" (1959). For Poland, see Sokolowska, *Kobieta pracująca* (1966).

<sup>4</sup> Investigations of time budgets to ascertain working-time inputs have been carried out rather extensively in a number of socialist countries. See, for example, Strumilin, *Problemy ekonomiki truda* (1957), pp. 233-359; Artemov et al., *Statistika biudzheto vremen* . . . (1967); Staikov, *Byudzheto na vremeto* . . . (1964); Strzemińska, *Wyniki badania budzetu czasu* . . . (1964); Sokolowska, *Kobieta pracująca* (1966); Laur, "Statistika nerabochego vremen . . ." (1966). On other aspects of the relationship between the statistical measure of the labour force and the economic concept of labour supply, see Long, *The Labor Force under Changing* . . . (1958), appendix E.

<sup>1</sup> The term "labour force" is used here as the equivalent of "economically active population" in the terminology of international standards for census concepts. Other terms for the economically active population are also found in the literature: "gainful workers", "gainfully employed persons", "working force", "manpower" etc.

important than its quantitative dimensions. In addition to the more strictly demographic characteristics—such as sex ratio and age structure of the labour force—the skills, experience, aptitudes, education and health of workers and the factor of motivation are among the primary determinants of the productive power and growth potential of the economy. The importance of these factors has gained increasing recognition in recent works on the conditions of economic progress and problems of economic development in less developed areas.<sup>5</sup> Altogether, these quantitative and qualitative considerations call for an integrated approach to manpower planning. The manpower balance sheet technique, which has been developed in centrally planned economies, has proved useful in this connexion. It involves a detailed assessment of present and future manpower resources and reserves (by sectors of the economy, skills, geographic region etc.), as well as of present and future manpower requirements, and thus provides the basis for estimating required changes in manpower allocation and for taking measures to effect such changes.<sup>6</sup>

5. The occupational structure of the labour force, its distribution among industrial sectors, and rural-urban and regional distribution within the country are highly relevant to productivity and economic growth. The processes of industrialization and growth of output per head require progressive adaptations of these features of labour force structure and distribution. In part, these are reflections of the changing conditions of demand for labour—that is, of the economic factors which determine the number, character, and location of opportunities for employment, including self-employment. But these economic factors operate within a demographic, institutional and cultural framework which conditions the labour force structure and distribution and the changes in these respects in the course of time. Demographic and cultural factors play an important part in determining the size and growth of the labour force as a whole and its numerical proportion to the population; and they may have appreciable influences also on the rates of unemployment and underemployment and the development of qualitative attributes of labour supply.

6. Section A of this chapter presents a world picture of the labour force, including its size in relation to the total population of different regions, and changes in this relationship over time. Patterns and trends of labour force participation among different sex-age groups, and among women differing in their marital status and child-care responsibilities, are also examined. The main focus of section B is on the role of demographic factors in determining the size, growth and distribution of the labour force, though these are considered in the context

of economic and cultural determinants. Section C discusses tables of working life and related measures, and section D, variations in types of economic activities and their changes in the course of economic development. Measures and levels of unemployment and underemployment are considered in section E. The study of the economic implications of labour force characteristics and changes, and of employment and unemployment conditions, leads farther beyond the boundaries of demography. Such implications are considered only incidentally here, and some of them are treated in other chapters.

### A. Levels and trends of the labour force

7. The principal source of labour force statistics for most countries is the population census, although census-type demographic sampling surveys have been developed recently in some countries as a valuable supplementary source, providing current measures of the labour force, employment and unemployment.<sup>7</sup> Data on the male and female components of the labour force were available from censuses taken during 1955-1964 in 141 countries, representing about 64 per cent of the estimated world population as of 1967. While the great majority of the population in North and South America, Europe, the Soviet Union and Oceania was represented by such data, the representation was relatively poor for Africa (44 per cent) and Asia (50 per cent).<sup>8</sup> The coverage of historical series of labour force statistics for countries in the less developed regions is especially narrow, being limited in most cases to data from one or two censuses.

8. Variations in the definitions applied in the censuses impair the comparability of labour force statistics for different countries,<sup>9</sup> and also often of data from successive censuses for the same country.<sup>10</sup> Among the principal points of variation are:

(a) The time-reference of the census questions on economic activities, which may vary from a single day to one year, or may vaguely refer to the individual's "usual" status;

(b) The treatment of persons engaged both in economic and non-economic activities;

(c) The criteria for identifying unemployed persons; and

(d) The distinction in farm households between members to be classified as in the labour force and those

<sup>7</sup> Employment and unemployment statistics are also derived from various other sources in many countries, but these usually lack the comprehensive coverage of the population census.

<sup>8</sup> United Nations, *Demographic Analysis of Manpower Development* ... (1970), annex III.

<sup>9</sup> See, for example, United Nations, *Application of International Standards* ... (1951), pp. 5-17; ———, Economic Commission for Europe, *European Population Censuses: the 1960 Series* (1964), pp. 79-85; You, "Growth and structure of the labour force ..." (1963).

<sup>10</sup> See, for example: (for India) Sinha, "Comparability of 1961 and 1951 ..." (1964); (for Jamaica) Cumper, "A comparison of statistical data ..." (1964); (for the Philippines) United Nations, *Population Growth and Manpower* ... (1960); (for Israel) Hovne, *The Labor Force in Israel* (1961), appendix A; (for the United States of America) United States, Bureau of the Census, *Estimates of Labor Force, Employment* ... (1944).

<sup>5</sup> For example, Galenson and Pyatt, *The Quality of Labour and Economic Development* ... (1964); Harbison and Myers, *Education, Manpower and Economic Growth* ... (1964); Correa, *The Economics of Human Resources* (1963), and Becker, *Human Capital* ... (1964).

<sup>6</sup> See, for example, Ulyanova, "The methods of drawing up the current and planned balances ..." (1967); Sonin, "Manpower balance in the USSR" (1966); and his *Vosproizvodstvo rabochei sily* ... (1959); Litvyakov, "Planirovanie ratsionalnogo ..." (1965); Kostakov and Litvyakov, *Balans truda* ... (1965); Lengyel, "A foglalkoztatottság ..." (1968).

not economically active.<sup>11</sup> Measurement of the labour force is extremely difficult under conditions prevailing in the rural areas of many less developed countries where a labour market scarcely exists.

9. In addition to the variations of definitions, census measures of the labour force and its components are affected to a great extent by various kinds of errors and biases which may result either from the respondents' inability to recall and report the facts accurately, or from enumerators' preconceptions as to the normal and proper roles of individuals according to sex, age, marital status, position in the family etc. They may also be affected considerably by the form and arrangement of the census questions on economic activities, the organization of the field work, and the training of interviewers.<sup>12</sup>

10. The variations in definitions, errors and biases affect in particular the statistics on the female labour force. For this reason international comparisons of labour force data are sometimes made for the male labour force alone. Alternatively, the category of unpaid workers—a group particularly sensitive to variation in definitions and procedures—is sometimes subtracted from the labour force for purposes of international comparisons. However, where there are real differences between countries in the contributions made by women or unpaid family workers of either sex to the labour supply, exclusion of these groups from the statistics does not provide a satisfactory basis for comparisons.<sup>13</sup>

## 1. THE TOTAL LABOUR FORCE

11. The two factors which determine the proportion of a country's population that is in the labour force are: (a) the propensity to participate in the labour force as reflected in activity rates for the different sex-age groups; and (b) demographic factors, principally the sex-age structure of the population, which is determined by fertility, mortality and migration.<sup>14</sup> There are considerable differences in the percentage of total population in the labour force, that is, in crude activity rates, as estimated for the different regions of the world. According to estimates of the International Labour Office presented in table IX.1, nearly 1,300 million persons belonged to the world's labour force in 1960, constituting 43 per cent of total world population. Owing largely to a higher

<sup>11</sup> For international recommendations on these subjects see United Nations, *Handbook of Population* ... (1958), vol. 2, pp. 24-28; International Labour Office, *Concepts and Methods* ... (1963), annex I, pp. 92-94.

<sup>12</sup> In the United States of America, the labour force totals enumerated in the 1950 and 1960 censuses were smaller by several million than those indicated by current sample surveys for the same dates and with the same definitions—a fact attributed mainly to better organization and training of field workers for the current surveys. See United States of America, President's Committee to Appraise Employment and Unemployment Statistics, *Measuring Employment and Unemployment* (1962), appendices J and K; Bancroft, *The American Labor Force* ... (1958), appendix A.

<sup>13</sup> See United Nations, *Demographic Aspects of Manpower* ... (1962), pp. 7-8.

<sup>14</sup> Sadie, "Demographic aspects of labour supply ..." (1966), p. 219. For a conceptual framework for analysing factors affecting the labour force participation of different sex-age groups, see Bowen and Finegan, *The Economics of Labor Force Participation* (1969), pp. 16-29. See also Becker, "A theory of allocation of time" (1965).

proportion of persons in the working ages, the more developed regions had a higher activity rate—about 45 per cent—compared with the estimated 42 per cent for the developing regions.

12. Within each of the two major areas, there was considerable regional variation. Among the more developed regions, activity rates are highest in Eastern Europe and the USSR, owing to the utilization of a large proportion of female workers. They are considerably lower in Northern and Western Europe, and lower still in Southern Europe, Northern America and Oceania. Among the developing regions, a marked contrast is noted between Asia and Africa—with relatively high rates—and Latin America, where rates are much lower. The much more frequent employment of women in agriculture in the former regions explains the major part of these differences. Whereas only about one fifth of all workers in Latin America were women, in Africa this figure was estimated to be close to one-third, and it may be still higher in Asia—if the high proportion estimated for China (41 per cent) is anywhere near the truth. The limited data on which the estimates for Africa are based suggest quite high levels of female participation in the labour force in Middle and Western Africa, and extremely low levels in Northern Africa.

13. Variations in the extent of female participation in the labour force also occur among the more developed regions. Women constituted slightly more than half of the labour force in the Soviet Union and over 40 per cent in Eastern Europe, but only 25 per cent in Australia and New Zealand.

14. It is estimated that between 1950 and 1960, the world's labour force grew by more than 200 million, with 141 million added in Asia, 16 million in the USSR, 17 million in Africa, 14 million in Latin America, 11 million in Northern America, 10 million in Europe and one million in Oceania (table IX.2.). For the world as a whole, the crude activity rate is estimated to have remained at about 43 per cent in 1950 and 1960. Small declines in crude activity rates were estimated to have occurred in most of the more developed regions. Demographic trends during the 1950s in these regions favoured a lower crude activity rate, since both the proportion of children and of older persons in the population increased at the expense of the working age group. This change in population structure, in combination with falling activity rates at the young and older ages, reduced the crude activity rate for males from an estimated 61 per cent in 1950 to 58 per cent in 1960. In the case of females, however, rising activity rates, particularly at ages 25 to 54 years, were sufficient to offset the effects of demographic trends, and the average crude activity rate rose from about 32 to 33 per cent during the decade.<sup>15</sup>

15. In the developing regions, a small decline in the proportion of population in the working ages and declining activity rates among certain age groups caused the crude activity rate for males to fall from 58 to 55 per cent between 1950 and 1960. Female activity

Note: Because of rounding, totals are not in all cases the exact sum of the parts.

rates are also estimated to have fallen slightly in South Asia and Africa, but these trends were offset by the substantial rise estimated for the mainland region of East Asia.<sup>16</sup> It must be pointed out that, owing to the inadequacies of available data, trends in activity rates in the world's developing regions are difficult to determine and those suggested in the International Labour Office estimates may be subject to considerable error.

16. The current prevailing trend in most parts of the world thus seems to be one of decreasing crude activity rates—in other words, of labour force growth lagging behind the growth of population—which results in part from a declining proportion of population in the working ages and from a widespread tendency towards decreasing specific activity rates for males in the youngest and eldest brackets of potential working ages. This is partly counteracted by increasing activity rates for females in certain parts of the world, although elsewhere the trend for female rates also is downward.

17. Earlier in the century demographic trends among the economically more developed countries favoured a rising activity rate. Due to the decreasing secular trend in birth rates in these countries, there was a rising proportion of population in the working ages<sup>17</sup> which counteracted the declining specific activity rates resulting from factors such as extended school attendance and earlier retirement. According to Bairoch and Limbor's recent analysis of long-term trends in the labour force in the world and its major regions, crude activity rates rose between 1900 and 1920 in those regions of Europe which had long been industrialized, but declined thereafter. In North America a gradually rising trend in the crude activity rate during the first half of the twentieth century was reversed after 1950. For the developed regions as a whole, the estimates show the labour force increasing from 273 million in 1900 to 445 million in 1960—or by nearly two thirds. At the same time, the total population in these regions was expanding by roughly three fourths.<sup>18</sup>

18. According to the less reliable estimates prepared for the world's developing regions, labour force growth is also shown to have lagged behind population growth in those regions. In absolute numbers, the labour force is estimated to have grown from about 477 million in 1900 to 817 million in 1960. This increase of about 70 per cent compares with a near doubling of the total population during the same 60-year period.<sup>19</sup>

19. Although changing activity rates cause the growth of the labour force to diverge from parallel with the population trend—and sometimes even to move in a contrary direction<sup>20</sup>—population growth has generally

played the dominant role in shaping long-range trends of labour force growth in various parts of the world during modern times. For example, in the United States of America between 1890 and 1940, as the growth of population decelerated with the falling birth rate and decreasing immigration, the rate of growth of the labour force diminished steadily from an annual average of 2.7 per cent in the decade of the 1890s to 1.1 per cent in the 1930s, although the trend of the crude activity rate was persistently upward. Of the total increase of roughly 30 million in the United States labour force during those fifty years, approximately 25 million was attributable to the growth of population, 2.5 million to the increase of the crude activity rate, and the remainder to interaction between the two factors.<sup>21</sup> In France, where the crude activity rate rose from 44 per cent in 1881 to 56 per cent in 1921 and declined slightly thereafter, the annual rate of growth of the labour force dropped, as population growth slackened, from about 1 per cent around the end of the nineteenth century to 0.2 per cent during 1926-1931, and the labour force decreased slightly during 1931-1936.<sup>22</sup> More recently, the revival of the French birth rate together with immigration from neighbouring countries has brought about renewed growth in the population and labour force in France.

20. In less developed countries during recent decades, the trends of labour force growth have been dominated by the sharply accelerating rates of population increase. In India, for example, although the crude activity rate dropped from an average of 47 per cent of the population at the censuses of 1901, 1911, and 1921 to 43 per cent in 1931 and 39 per cent in 1951, the rate of growth of the labour force rose from an average of about 2.5 per cent per decade between 1901 and 1931 to 6 per cent per decade between 1931 and 1951, and shot up to 34 per cent in the decade 1951 to 1961 (according to one interpretation of the relationship between the 1951 and 1961 census measures).<sup>23</sup> It appears likely that such a trend has been fairly typical of the recent experience of less developed countries, although long-range series of labour force statistics are lacking in most of them.<sup>24</sup>

<sup>21</sup> Durand, *The Labor Force in the United States* ... (1948), pp. 19, 22. Lebergott, *Manpower in Economic Growth* ... (1964), p. 510, gives estimates of the growth of labour force and employment in the United States of America since 1800.

<sup>22</sup> Desmarest, *La politique de la main-d'œuvre* ... (1946), pp. 13-15, 53-54, 70-74. See also Daric, *Vieillessement de la population* ... (1948).

<sup>23</sup> Kalra, "A note on working force ..." (1962), tables 2 and 3. These estimates were made by adjusting the classifications of 1951 and earlier census years for conformity with the new labour force definition adopted in the 1961 census. They indicate an increase in the crude activity rate from 39 per cent of the population in 1951 to 43 per cent in 1961, but this change appears dubious. Estimates derived from the national sample surveys of 1953-1954, with a labour force definition similar to that of the 1961 census, indicated a crude activity rate of 43.8 per cent.

<sup>24</sup> Egypt may be one exception. According to the results of censuses in that country since 1927 and recent labour force sampling surveys (if their comparability can be trusted), the rate of growth of the Egyptian labour force has diminished in spite of the accelerating growth of the population. The crude activity rate would appear to have dropped from 65.2 per cent of the population in 1937 to 52.3 per cent in 1957. See Seklani, "Population active et structures économiques de l'Égypte" (1962).

<sup>16</sup> International Labour Office, *Labour Force Projections* ... (1971), part V, table 2.

<sup>18</sup> Bairoch and Limbor, "Changes in the industrial distribution ..." (1968), pp. 314-315.

<sup>19</sup> *Ibid.*

<sup>20</sup> A striking example was the wartime expansion and post-war contraction of the labour force in countries involved as belligerents in the Second World War. See Long, *The Labor Force under Changing* ... (1958), chap. 2; Saunders, "Manpower distribution, 1939-1945 ..." (1946).

## 2. DEPENDENCY BURDEN

21. The application of economic analysis to population structure and change has revealed that one of the comparative disadvantages of developing countries, vis-à-vis developed countries, lies in their heavy dependency burden resulting from high fertility. Coale and Hoover have observed that a rapid growth in the number of dependants imposes greater claims on the income produced by the working population.<sup>25</sup> Families with a large number of children are likely to be less able to save, and as a result, the level of investment is likely to be lower. When a large proportion of national investment is provided by the government, high fertility is likely to reduce the government's capacity to raise money for investment through taxation. Populations with a high child dependency ratio must divert a larger proportion of investment funds to less immediately productive uses, for example to housing rather than to factory construction.<sup>26</sup> Moreover, the strain on educational facilities resulting from rapid growth in the child population may impede progress in reducing illiteracy and in providing adequate training for future entrants into the labour force.<sup>27</sup>

22. While there has been much discussion of the disadvantages of high dependency burdens, few studies have attempted to measure differences in dependency loads between countries, owing to the difficulties of obtaining satisfactory statistical measures. As discussed in chapter VIII, section A, the ratio of persons in dependent age groups to those of working ages gives a first approximation of a country's dependency burden. But not all persons of working age participate in economic activities, while, on the other hand, certain persons below or beyond what are considered the normal working ages are employed. Therefore a more accurate assessment of dependency is obtained from the activity classification of the population in the census. Utilizing such data, Ulanis has defined several different measures for studying the dependency burden. These include: (a) the number of inactive persons per economically active persons; (b) the number of inactive and unemployed persons per employed person; (c) the number of dependants of individuals per economically active person; and (d) the number of dependants of individuals per employed person.<sup>28</sup> Although these refinements give additional

<sup>25</sup> Coale and Hoover, *Population Growth and Economic Development* ... (1958), p. 234.

<sup>26</sup> Coale, "Population and economic development" (1963), pp. 54-55.

<sup>27</sup> Coale and Hoover, *Population Growth and Economic Development* ... (1958), p. 236.

<sup>28</sup> Comparing the dependency burden of the Soviet Union and the United States in 1959 according to these four indices, Ulanis found the following results:

	USSR	USA
Number of inactive persons per economically active	0.98	1.61
Number of inactive and unemployed per employed	0.98	1.80
Number of dependants of individuals per economically active	0.81	1.38
Number of dependants of individuals per employed	0.81	1.48

Ulanis, *Dinamika i struktura* ... (1964), pp. 48-49. For other analyses of age structure and dependency, see Sonin, "Aktualnye problemy uluchsheniia ..." (1967), pp. 256-257; and Ulanis, "Dinamika i struktura naseleniia SSSR" (1967), pp. 156-160.

insight into economic-demographic relationships, even they are far from satisfactory, not only because of the inadequacies of the census data on the labour force and the employed population, but also because the amount of time spent at economic activities and the value of the product produced vary for different age groups. A better index of the dependency burden could be obtained if data were available to compute the average value of product produced against that consumed for each age group.<sup>29</sup> Information on which to base such calculations is at present lacking, however, for most countries.

23. As shown in table IX.1, the dependency burden, computed in terms of the number of inactive persons per 100 economically active, is greater in the developing regions than in the more developed, but the gap between the two does not appear as wide as it does when age structure alone is considered.<sup>30</sup> Computed on the former basis, there are, on the average, 140 dependants per 100 active persons in the developing regions, compared with 122 in the world's more industrialized regions. Except for small areas in Oceania, the lowest dependency ratios (less than 100 dependants per 100 active) are found in the Soviet Union and Eastern Europe, owing in part to the high female labour force participation rates reported for those regions. At the other extreme, exceptionally high dependency ratios are shown in most parts of Latin America (over 200 dependants for each 100 active in Tropical South America and Middle American Mainland), as well as in Northern Africa.

## 3. THE MALE LABOUR FORCE

24. Of the estimated labour force of the world in 1960, males constituted nearly two thirds and females only a little over one third. The crude activity rate for males—that is, the male labour force as a percentage of total male population—was estimated to be 56 per cent (table IX.3). Owing to differences in age structure, the male population of industrialized regions averages higher proportions in the labour force (58 per cent) than the developing regions (55 per cent). Average activity rates for Latin America, Africa and Asia varied only from 53 to 55 per cent. Within the more developed regions, however, a much wider range of variations is seen. Whereas 62 per cent of the male population of Europe was economically active in 1960, the corresponding figure was only 54 per cent in North America.<sup>31</sup> The range of male activity rates in individual countries is, of course, much greater. Extremely low male activity rates were reported in Puerto Rico (38.7 per cent in 1960) and among the African population of Zambia (33.8 per cent in 1963). On the other hand, Romania (1956), Portugal (1960) and the Sudan (1956) reported some of the highest rates (66-67 per cent).<sup>32</sup>

<sup>29</sup> See the discussion in Durand, "Population structure as a factor ..." (1953), pp. 2-3. See also United Nations, *Methods of Analysing Census Data* ... (1968), pp. 13-14.

SOURCE: Based on International Labour Office, *Labour Force Projections* ... (1971), part V, table 2.

25. Despite some exceptions, it is clear that the proportions of male population in the labour force are generally higher in the more developed, than the developing countries.<sup>33</sup> On this account, the more developed countries would have an economic advantage even if output per worker were the same in all countries.

26. As noted above, this advantage of the more developed countries is due to the relatively small proportion of children and large proportion of adult population which result from a low birth rate. Without this difference in population structure, crude activity rates would be lower in the more developed than in developing countries, since the latter have higher age-specific activity rates (see table IX.3).

#### (a) Age-specific male activity rates

27. Differences between the patterns of age-specific male activity rates in different countries—and changes in any country in the course of time—primarily reflect variations in the age of entrance into the labour force and in the age of retirement or involuntary withdrawal into inactive status. Custom dictates in every society that able-bodied men in the intermediate ages should be engaged in income-producing work, and most of those not actually employed are likely to be reported as labour force members, in the unemployed category. Male activity rates exceeding 90 per cent in the age groups between 25 and 54 years are the general rule in countries at all levels of industrialization. Rates are found to be lower in the more developed countries than in developing countries in the age groups below 20 and over 55 years, and particularly in the extreme age groups, under 15 and over 65 years, as shown in table IX.3. These differences reflect the fact that males in the more developed countries

enter the labour force later and withdraw earlier in life, on the average, than they do in the developing countries.<sup>34</sup>

28. In addition to entering the labour force later and withdrawing earlier in life, male workers in the relatively wealthy industrialized countries put in shorter hours of work per week, on the average, than do workers in the less developed agricultural countries.<sup>35</sup> Thus, the age-specific activity rates give a distorted notion of the contribution of different groups to labour supply, since they take no account of variations in the extent of activity of labour force members. In assessing inputs to labour supply, it should be taken into consideration that part-time workers are proportionately more numerous in the youngest and eldest than in the central age groups.

29. The difference between the more developed and less developed countries in patterns of participation by males in the labour force has a counterpart in rural-urban differences within countries.<sup>36</sup> Males in rural communities generally enter the labour force earlier, on the average, and continue working to more advanced ages than they do in the cities.<sup>37</sup> In a study of age-specific

<sup>34</sup> Findings of other studies on the relationship between levels of male activity rates and the level of development are similar. See, for example, United Nations, *Demographic Aspects of Manpower* ... (1962), table 3.2.; Ducoff, *Human Resources of Central America* ... (1960); United Nations, *Population Growth and Manpower* ... (1960), p. 55; Correa, *The Economics of Human Resources* (1963), p. 21; Sadie, "Población y mano de obra ..." (1969), p. 35.

<sup>35</sup> Winston, "An international comparison of income ..." (1966).

<sup>36</sup> Examples of works in which urban-rural differentials in activity rates have been analysed are: United Nations, *Studies of the Economically* ... (1959), pp. 28-32; ———, *Population Growth and Manpower* ... (1960); ———, *The Mysore Population Study* ... (1961), chap. 15; Seklani, "Population active et structures économiques de l'Egypte" (1962); Sadie, "The white labour force ..." (1960); Yuan, "Relation of type and size ..." (1965); Taeuber, *The Population of Japan* (1958), chap. 5; Bancroft, *The American Labor Force* ... (1958), chap. 3; Kim, "Labour force structure in a dual economy ..." (1970). Estimated age-specific male activity rates in the agricultural and non-agricultural sectors in Brazil's population, 1940 and 1950 projections for 1960, are given in Arretx, *Población masculina económicamente activa* ... (1963), table 3, annex.

<sup>37</sup> An exception to the rule of lower average age of entrance into the labour force in rural areas was found in Japan before the Second World War; see Taeuber, *The Population of Japan* (1958), pp. 85-86.

<sup>33</sup> An analysis of 1950 census data showed that male activity rates averaged 62 per cent in industrialized countries (defined as having less than 35 per cent of the male labour force engaged in agriculture), 58 per cent in semi-industrialized countries (those having 35 to 59 per cent in agriculture) and 55 per cent in agricultural countries (those with 60 per cent or more in agriculture). United Nations, *Demographic Aspects of Manpower* ... (1962), table 2.4.

TABLE IX.4. URBAN AND RURAL ACTIVITY RATES AND GROSS YEARS OF ACTIVE LIFE,  
FOR SELECTED COUNTRIES

Areas		Crude activity rate (labour force as percentage of total population)			Gross years of active life in age range 15-74 years	
		Both sexes	Male	Female	Male	Female
Guatemala, 1950:	Urban .....	37.7	57.1	19.6	53.9	15.7
	Rural .....	33.0	59.5	5.1	57.3	4.5
Indonesia, 1961:	Urban .....	32.8	48.8	16.7	47.8	16.0
	Rural .....	36.5	53.3	20.1	54.0	20.7

	Rural .....	52.4	56.4	48.7	54.6	44.2

SOURCES: Calculated from data shown in: Ducoff, *Human Resources of Central America* ... (1960), p. 142; Japan, Bureau of Statistics, *1955 Population Census* ... (1957), vol. 2, part 2, p. 34; United States of America, Bureau of the Census, *Census of Population, 1960* ... (1963), table 194; Indonesia, Central Statistical Office, *Sensus penduduk 1961* ... (1961?); Poland, Główny Urząd Statystyczny, *Rocznik demograficzny, 1945-1966* (1968), pp. 86-87; Smolinski, "Statystyczne metody mierzenia ..." (1965), p.11. In computing gross years of activity rates for Japan and Poland, activity rates for certain age groups had to be estimated by graphic interpolation; the census tabulations for Japan provide no subdivisions of the age group 65 years and over in the labour force and those for Poland provide no subdivision of the 70 to 79-year group.

activity rates in forty countries, based on 1960 census data, it was found that rural activity rates for males surpassed the urban in all age groups, though the differences were greatest at ages under 20 and over 64 years and relatively slight at ages between 25 and 54. When the data were examined separately for more developed countries and less developed countries, generally similar patterns were found in both groups.<sup>38</sup> It may be concluded that increasing urbanization of a country at any level of economic development tends to reduce the male activity rate, other things being equal.<sup>39</sup> Yet the crude male activity rate is sometimes higher in the urban than in the rural population, because age-selective migration from the countryside to the cities inflates the proportion of young adults in the city population<sup>40</sup> (and also, in some countries, because the urban population has lower fertility than the rural).

30. A summary measure of the level of age-specific activity rates in urban and rural areas which eliminates the effects of differences in age structure is provided either by age-standardized activity rates or by calculating the gross years of active life. Applying the former measure, Denti found that the average activity rate in

forty countries studied was 52.2 in urban areas and 56.5 in rural areas.<sup>41</sup> The measure of gross years of active life, which has the advantage of not being affected by the arbitrary choice of a standard age distribution, is the sum of products of the age-specific rates multiplied by the number of years in the corresponding age groups. It represents the average number of years in the labour force for a hypothetical generation of males (or females) calculated on the assumption that all would survive up to the end of the potential span of working life and that they would have at each age the specific activity rates observed in a given population. A few examples of differences in gross years of active life and total activity rates are given in table IX.4. It is seen that the gross years of active life for males are higher in the rural than in the urban areas of each of the five countries studied, though in two of the countries (Japan and the United States of America) crude male activity rates were higher in the urban areas.

31. A significant negative correlation between activity rates and school attendance rates of males 10-14 and 15-19 years of age was found in an analysis of data for 30 countries.<sup>42</sup> This association existed even though part-time and seasonal employment of students is not uncommon in many countries, and on the other hand, teen-age males reported as neither in school nor in the labour force are disquietingly numerous in some less developed countries.<sup>43</sup> So the average age of entrance

<sup>38</sup> Denti, "Sex-age patterns of labour force participation ..." (1968), pp. 533-534.

<sup>39</sup> It is important to note that the inverse association between urbanization and activity rates is closely linked to other factors such as education and industrial composition of the labour force. In an analysis of 1961 activity rates by census district in India, it was found that when the influences of literacy, density and the industrial composition of the labour force were eliminated, the association between activity rates and degree of urbanization was not statistically significant. Namboodiri, "A contribution to the study of factors ..." (1966), pp. 51-52.

<sup>40</sup> See, for example, Daragan, "Economic development and internal migration" (1967).

<sup>41</sup> Denti, "Sex-age patterns of labour force participation ..." (1968), p. 536.

<sup>42</sup> United Nations, *Population Growth and Manpower* ... (1960), p. 55.

<sup>43</sup> Such conditions have been interpreted as a result of deficient opportunities for employment discouraging young people from seeking jobs. For example, see United Nations, *Studies of the Economically* ... (1959), p. 27.

of males into the labour force is to a large extent a function of social norms with regard to levels of educational attainment, reinforced by compulsory school attendance laws and legal restrictions on child labour as well as by public provisions for education. Likewise the average age of retirement is partly governed by social norms, which are backed up in this case by public or private provisions for old-age and disability pensions and, in some countries, by governmental efforts to prevent aging workers from being forced out of the labour force prematurely by discriminatory employment practices. Economic and demographic circumstances condition the formation of these norms and the corresponding provisions of law and public policy. In less developed countries, low incomes and high birth rates making for a large proportion of children in the population inhibit long schooling, late entrance into the labour force, and early retirement. At the same time, the organization of the less developed rural-agricultural economy largely in small-scale family units of production makes it relatively easy to put children to work early and affords opportunities for men to continue doing at least some work up to an advanced age—opportunities which may be difficult to find in the wage-earning régime of the urban-industrial economy.

#### (b) Trends of male activity rates

32. Gross years of active life for males in industrialized countries have been decreasing—at least since the early decades of the present century—as a result of decreasing activity rates at both ends of the span of potential working life.<sup>44</sup> Below the age of 14 or 15 years, activity rates for both males and females in industrialized countries have dwindled almost to the vanishing point; in fact, it is no longer considered worth while in the censuses of most of these countries to inquire about economic activities of persons below such an age. Although the trend in the age group 15-19 years has been less consistent, the average male activity rate in this age group for ten industrialized countries is estimated to have decreased from about 80 per cent around 1920 to 70 per cent around 1950. For men 65 years of age and over, the decrease was from about 65 per cent in 1920 to 45 per cent in 1950, and there has also been a noticeable decline in the rate for men between 55 and 65 years of age.<sup>45</sup> Data from more recent censuses show that these trends have continued in industrialized countries since the Second World War. In fourteen of fifteen industrialized coun-

tries<sup>46</sup> where comparable data were obtained in two post-war censuses, the activity rate for males 15-19 years of age decreased during the intercensal period, the average amount of the decrease being about 9 per cent (on a per-decade basis) of the male population in this age group. The rate for males 65 years of age and over decreased without exception in these 15 countries, the average amount of decrease being about 11 per cent (see table IX.5).<sup>47</sup>

33. The causes of the compression in the years of active life between a rising average age of entrance into the labour force and a falling average age of retirement are entwined with developments that have played essential parts in the evolution of modern industrial societies. Increasing need and increasing opportunities for extended education are the counterparts of the rising trend of average age of entrance; the relationship between rising rates of school attendance and falling activity rates for teen-age males in industrialized countries has been demonstrated statistically.<sup>48</sup> The trend towards earlier retirement (or forced withdrawal from the labour force on account of physical disability or other handicaps associated with advanced age) is related to the decrease of agriculture's share in the labour force, the growing proportion of men who work as employees and diminishing opportunities for self-employment,<sup>49</sup> as well as to the development of social security legislation and other provisions for retirement income.<sup>50</sup> The growth of output per worker can also be considered as a fundamental factor in promoting this curtailment of active life at the two ends, since this provides the means of supporting longer preparation for work and longer maintenance in retirement.<sup>51</sup>

34. In assessing economic implications of trends in activity rates, it is important to take account of con-

<sup>44</sup> Industrialized countries are here defined as those having less than 35 per cent of their male labour force engaged in agriculture and related activities, semi-industrialized countries having 35 to 59 per cent, and agricultural countries having 60 per cent or more so engaged.

<sup>47</sup> See also Penniment, "The influence of cultural and socio-economic factors . . ." (1967), p. 319.

<sup>48</sup> Long, *The Labor Force under Changing* . . . (1958), p. 112. In the United States during recent decades, there has been an increase in part-time student employment, but not enough to prevent the continuing decline of male activity rates at ages below 20 (except temporarily during the war decade of the 1940s); see Bancroft, *The American Labor Force* . . . (1958).

<sup>49</sup> Notestein *et al.*, *The Future Population of Europe* . . . (1944), p. 160, summed up this aspect of the matter aptly with the following words: "In agriculture, the handicrafts, and the keeping of small shops the process of retiring can be gradual and adjusted to the weakening faculties of the individual. As the economy has become more complex with larger and less flexible units and more narrowly specialized occupations, individuals tend to be employed fully or not at all. It becomes difficult to find a place for the person who fails to keep the general pace. Moreover rigid prescriptions that ignore the capacities of the individual tend to lower the age of retirement."

<sup>50</sup> There is a vast literature on causes of the decreasing trend of activity rates of elderly men in the industrialized countries. For example, see Daric, "L'organisation scientifique du travail . . ." (1948); Desmarest, "Le régime des pensions de vieillesse . . ." (1948); Long, *The Labor Force under Changing* . . . (1958), chap. 5; United Kingdom, Royal Commission on Population, *Report* . . . (1949), pp. 114-116; Rosset, *Ludzie starzy* . . . (1967).

<sup>51</sup> See section B.

<sup>44</sup> At an earlier stage in the industrial development of Western countries, child labour is believed to have increased; for example, on child labour in England, see Marshall, "The population problem during . . ." (1954), and Dunlop, *English Apprenticeship and Child Labour* . . . (1912). The censuses of the United States in the latter decades of the nineteenth century showed an increasing trend of male activity rates in the youngest age groups, but the reliability of these data is dubious; see Lebergott, "Population change and the supply of labor" (1958). See also Daric, *Vieillesse et de la population* . . . (1948), p. 85.

<sup>45</sup> United Nations, *Demographic Aspects of Manpower* . . . (1962), figure 2, p. 16, and table A-5. See also Bourgeois-Pichat, "Perspectives sur la population active européenne" (1953).

SOURCES: Calculated from data in United Nations, *Demographic Aspects of Manpower* ... (1962), tables A-1 and A-3; ———, *Demographic Yearbook, 1956* ... (1957); ———, *1964* ... (1965); and van den Boomen, "Population and labour force growth ..." (1967).

<sup>a</sup> Unweighted mean of changes in rates, pro-rated to a per-decade basis where the intercensal periods were greater or less than 10 years.

<sup>b</sup> Including one country with no change in activity rate.

comitant changes in the amounts of labour input per worker. It is well known that average hours of work per week have followed a decreasing secular trend in industrialized countries. Taking this factor into account, it has been estimated that labour-time inputs per 1,000 males 14 years of age and over decreased in the United States of America by 41 per cent between 1890 and 1950, in Great Britain by 27 per cent between 1911 and 1951, and in Germany by 29 per cent between 1895 and 1950. In the female population, although the trend of activity rates was upward in the United States and Germany, this was more than counterbalanced by a decrease in weekly hours per worker, so that hours of labour input per 1,000 females 14 years of age and over decreased by 5 per cent in the United States of America and 7 per cent in Germany during the first half of the present century.<sup>52</sup>

<sup>52</sup> Long, *The Labor Force under Changing* ... (1958), chap. 13. In the United States between 1909 and 1964, it has been estimated that average annual hours of work per head for the civilian labour force decreased from 2,662 to 1,999; the decrease was much greater in non-farm than in farm work. See United States, National Commission on Technology, *Automation and Economic Progress* (1966), vol. 1, p. 12. The intensity of work is another question. Wiles, "Notes on the efficiency ..." (1951), maintains that the pace of

35. The decreasing trend in activity rates for males under 20 and over 65 years of age are not confined to industrialized countries. With few exceptions among semi-industrialized countries where indications of changes during post-war intercensal periods are available, the trend has been downward in both of these age groups, and the average amounts of decrease in the rates have been comparable to the averages for industrialized countries (see table IX.5). In the agricultural group, although measures of the changes are available only for a few countries, the prevailing trend in the rates for males below age 20 has been steeply downward since the Second World War. Among men over age 65 also, the downward trend is apparent in some of the few countries for which data are available, but these data are not sufficient to indicate whether this trend is generally typical of agricultural countries.<sup>53</sup> International Labour Office estimates for 1950 and 1960 for the less developed regions as a whole show a considerable decline in the activity rates for men 65 years of age and over and

work in Britain nowadays is slower than it was in the nineteenth century.

<sup>53</sup> On recent changes in Asian countries, see You, "Growth and structure of the labour force ..." (1963).

under 20 years.<sup>54</sup> In India, the total activity rate in the male population appears to have been falling for half a century prior to the 1951 census; measures of long-range trends in the age-specific rates are not available.<sup>55</sup> In Jamaica, decreasing trends of the activity rates for males in the youngest and eldest groups have been traced back to the latter decades of the nineteenth century,<sup>56</sup> and in Puerto Rico, to 1910.<sup>57</sup>

#### 4. THE FEMALE LABOUR FORCE

36. The part taken by women in income-producing work varies enormously in different parts of the world. According to International Labour Office estimates for 1960, women constituted slightly more than half of the total labour force in the Soviet Union, and 42 per cent in Eastern Europe. At the other extreme, they made up only about 7 per cent of the labour force in Northern Africa, and 15 to 18 per cent in Tropical South America and the Middle American Mainland (see table IX.1.). In addition to the Soviet Union, there are a number of countries in tropical Africa whose recent census reports show females outnumbering males in the labour force; these include the Democratic Republic of the Congo, Guinea and Niger. A near equality of the sexes is also found in Thailand. On the other hand, in Kuwait, less than one female was reported as economically active for every hundred males so reported in the census.

37. The regional range of variation in female crude activity rates in 1960 was from 48 per cent in the Soviet Union to 4 per cent in Northern Africa, although individual country figures fell outside these limits. Rates of less than 3 per cent were reported in Jordan (2.6 per cent) and Kuwait (only 0.4 per cent). These exceedingly low figures are in contrast with the rates of more than 50 per cent reported in Thailand (51.4 per cent), among the African population of Guinea (51.4 per cent) and among the African population of Niger (57.3 per cent).<sup>58</sup>

38. In most countries, the census statistics are likely to understate the number of economically active women, especially in the category of unpaid helpers on farms and other family-operated economic enterprises. Differences in the extent of this under-reporting are partly responsible for the wide variations in recorded female activity rates. On the other hand, a full enumeration of all women engaged to any extent in economic activities would exaggerate their contribution to the labour supply, since relatively many female workers are part-time workers in most countries.<sup>59</sup>

39. The economic significance of variations in female activity rates is not the same as that for the variations in male rates, because most adult females who are not

in the labour force engage in productive activities within the home, rendering services and producing goods which are none the less valuable for not being counted as income. While the housewife not in the labour force may be regarded as dependent, she is not so in the same sense as a child or aged person who does not contribute to production. The apparent economic advantage for a nation in having a high female activity rate is to a large extent illusory if it results merely from women producing in paid employment the same kinds of services and goods which, under a different organization of the economy, they would produce without pay within the home.

40. Influences of culture are apparent in the international picture of variations in female activity rates. That some of the highest rates have been recorded in tropical African countries is not surprising in view of the fact that, in many societies in that part of the world, it has traditionally been women's responsibility to till the soil, plant, weed, and harvest the crops.<sup>60</sup> In West Africa, women are also renowned for their role as petty traders.<sup>61</sup> In contrast, the countries of Mediterranean Europe and Latin America form a group having generally rather low female activity rates, Bolivia being a notable exception. The Moslem countries form another such group, although there are some exceptions there, too.<sup>62</sup> The custom of "purdah" in Moslem societies inhibits employment of women.<sup>63</sup> Such traits of culture may affect not only the extent to which women actually engage in income-producing work but also the reporting of their activities in the census. For example, it has been surmised that the very small numbers of women reported as economically active in the conservative rural areas of upper Egypt might be due in part to reluctance to acknowledge the fact of their employment.<sup>64</sup>

41. In Western industrial societies, although employment of women outside the home no longer encounters the disapproval it did in former times, it is still inhibited in varying degrees in different communities by stereotyped ideas about the intellectual and physical capacities of women and traditional conceptions of their proper function as wives and mothers.<sup>65</sup> The feeling that they should not compete with men in their role as breadwinners is likely to be strengthened when there is much unemployment. In socialist societies, on the other hand, equality of the sexes in employment opportunities is emphasized as a principle of social policy<sup>66</sup> and female

<sup>58</sup> United Nations, *Demographic Yearbook, 1964* ... (1965), table 8.

<sup>59</sup> With reference to industrialized countries, see Bruntz, "The part-time employment of women ..." (1962).

activity rates are high: above 40 per cent in the USSR, Bulgaria and Poland and 31 to 33 per cent in Hungary and Yugoslavia according to censuses taken around 1960. These rates compare with a range of 13 to 36 per cent for Western European countries.<sup>67</sup> A comparable measure for China is lacking.<sup>68</sup> Other reasons which have been given for the current high female activity rates in socialist countries include the absorption of male manpower reserves as a result of rapid development, the educational advancement of women and the expansion of social legislation and facilities for child care.<sup>69</sup>

42. Regarding the effect of industrialization upon women's participation in economic activities, Sinha advanced the hypothesis that industrialization at an early stage makes for a decrease in their participation, and at a later stage for an increase.<sup>70</sup> Some support for this hypothesis was found in a comparison of average female crude activity rates for industrialized, semi-industrialized and agricultural countries, based on 1950 census data. While the average for industrialized and agricultural countries was found to be about the same (24 per cent and 25 per cent, respectively), the average for semi-industrialized countries was lower (21 per cent). Not much significance can be attached to this difference, though, in view of the wide variations of the rates among countries within all three groups.<sup>71</sup> The same observations apply to differences between female activity rates in countries classified by income per head, which have been found to be somewhat lower, on the average, for middle-income countries than for those in the lowest and highest

income classes.<sup>72</sup> No correlation is apparent between female activity rates and degrees of urbanization.<sup>73</sup>

43. Urban-rural differences of female activity rates in different countries do not conform to any consistent rule. Among the examples shown in table IX.4, the cases of Indonesia and Japan, with larger percentages of women in the rural than in the urban population classified in the labour force, appear to represent the dominant pattern in the Asian region.<sup>74</sup> The opposite differential, exemplified by statistics for Guatemala, seems to predominate in the Latin American region and it is also found in the United States and to a lesser extent among Western industrialized countries.<sup>75</sup> Whether the urban or the rural rate is higher depends largely on the extent of the reporting of women in farm households as unpaid helpers in agricultural work.<sup>76</sup>

44. The same diversity is found in the results of studies of regional variations in female activity rates within countries, associated with varying degrees of industrialization and other economic and social characteristics. A study of differences in the female rates for various states in India has shown, in the rural population, an inverse association with the percentage of rural workers engaged in non-agricultural industries, and in the urban population, an inverse association with the percentage of workers in "organized" industries (those having at least 50 per cent of the wage-earning labour force and 75 per cent or more of the labour force in non-household establishments). Negative correlations with measures of income and literacy were also found.<sup>77</sup> On the contrary, in Central American countries and Mexico, provincial differences of female activity rates were found to be associated positively with industrialization.<sup>78</sup>

45. In a study limited to the populations of metropolitan areas in various countries (thus minimizing the

(Footnote 66 continued)

"The participation of women ..." (1967); Litvyakov, "Economic and social factors in ensuring full employment ..." (1967), p. 310. Several writers have observed, however, that at the present stage of development of socialist societies, certain problems arising from this policy remain unsolved. For example, it has been recognized that in Yugoslavia, women's participation in social production often results in their carrying a double work load, since they have not been freed from most of their domestic duties in the home. For an extensive discussion, see Hadžiomirović, *Ekonomija ženskog rada* ... (1959), particularly pp. 354-360.

<sup>67</sup> United Nations, *Demographic Yearbook, 1964* ... (1965), table 8. Characteristics of the female labour force of the USSR and the United States are compared in Ulanis, *Dinamika i struktura naseleniia SSSR i SShA* (1964).

<sup>68</sup> In the non-agricultural sector of the Chinese economy, it has been estimated that 17.7 per cent of employed workers in 1958 were females. Emerson, *Sex, Age and Level of Skill* ... (1965).

<sup>69</sup> Rajkiewicz, *Zatrudnienie w Polsce Ludowej w latach 1950-1970* ... (1965), p. 55. See also Sergeeva, "Spetsifika primeneniia zhenskogo truda" (1969).

<sup>70</sup> Sinja, "Dynamics of female participation ..." (1965). There is some evidence to suggest that such a trend has occurred in Poland. Despite increases in non-agricultural activity rates for women during the interwar period, the average activity rate for all women 14 years of age and over declined owing to the outflow of population from agriculture. The total female activity rate stabilized in the 1950s, however, owing to a large increase in female employment in non-agricultural occupations. See Piotrowski, *Praca zawodowa kobiety a rodzina* (1963), p. 39. See also Penniment, "The influence of cultural and socio-economic factors ..." (1967), p. 320.

<sup>71</sup> United Nations, *Demographic Aspects of Manpower* ... (1962), table 2.4. The variations were especially wide among agricultural countries, with both the highest and the lowest recorded activity rates for females being found within this group. Interquartile ranges were 19.6 to 31.0 per cent in the group of industrialized countries, 13.4 to 28.5 per cent in the semi-industrialized, and 10.7 to 41.8 per cent in the agricultural group.

<sup>72</sup> Sinha, "Dynamics of female participation ..." (1965). Since many of the countries included in the middle-income group in this study were Latin American and Southern European countries, the question arises whether the relatively low average female activity rate for the group was related more to income or to culture.

<sup>73</sup> Stewart, "Degree of urbanization ..." (1967), table 4.

<sup>74</sup> Denti, "Sex-age patterns of labour force participation ..." (1968), p. 548. In India, the rural female activity rate recorded at the 1961 census was nearly three times the urban rate, and within the urban population, the rate diminished progressively with increasing city size. See Sinha, "Dynamics of female participation ..." (1965); and India, Cabinet Secretariat, *Tables with Notes on Employment* ... (1959). In West Malaysia, according to a 1962 survey, the lowest female activity rates occurred in large urban areas and the highest in rural areas, with those in small urban areas and metropolitan areas falling in between. Jones, "Female participation in the labour force ..." (1965), pp. 69-70. In the Philippines, on the other hand, female activity rates were not found to be lower in urban than in rural areas. Gupta, "Patterns of economic activity ..." (1970), p. 392.

<sup>75</sup> Regarding the Latin American countries, see van den Boomen, *Algunos aspectos de la actividad* ... (1962), chap. 3. In censuses of some European countries where many family members in farm households are classified as economically active in agriculture, female activity rates in the agricultural sector may exceed those in the non-agricultural sector. This is the case for France and Poland, for example, but it does not appear to be the general rule in Europe.
